I REMEMBER the first time the arc lights were exhibited in my native city, and what a tumult was caused at the telephone office. A circuit was strung up, using the ground for a return and four or five lights were placed upon it. Immediately on the starting of the dynamo, up went the lights, and down went the switchboard drops in the central station, and the confusion of tongues consequent upon the building of the tower of Babel was as the stillness of death compared to the racket on the telephone wires. I was called upon to prescribe for the patient and was obliged to look wise for awhile in order to gain time to concentrate my faculties and make a diagnosis. By a happy inspiration, more than by a reasoning process, I pronounced the disease a bad case of conduction, leakage or overflow of current caused by the use of the earth by the light' people. The remedy was evident; double the light circuit, which was done the next day, and the conduction fiend was exorcised. His twin brother, induction, still remained, but he "roared us as gently as a sucking dove" in comparison, which amelioriation of our condition was partly due to the fact that the heavy current circuit paralleled very few of the telephone lines.

As the electric light companies, whose name is now legion, increased throughout the country, the difficulties from leakage and induction naturally increased until now, especially when the low and high tension wires are on the same poles, the telephone service is more or less impaired. What would be the condition of that service if the electric light circuits were grounded instead of metallic?

Quite a number of expedients have recently been suggested for overcoming the difficulties caused by high tension currents acting through conduction and induction upon low tension circuits. The principal idea, or perhaps speaking more definitely, the one which we have heard the most about, is what is generally known as the McCluer system, which in a few words, consists in detaching the telephone wire from the earth at the distant end and connecting all wires together by means of a common return circuit to the central office or other point, at a distance, if possible, from the disturbing influence; or by a somewhat different method abandoning the use of the earth and connecting all wires together at the central office as well as at the other end. There is nothing in my judgment, particularly new about these ideas, and I am unable to think of any theoretical reasons why they should be curealls for the evils under which the telephone is prone to labor from too intimate association with its ferocious neighbors.

We have heard from time to time that most signal and triumphant successes have been scored in this, that or the other place, by means of the McCluer system, but upon investigation it strikes me that the results are a good deal like the sequel of the old story of the Three Black Crows. I do not think that the laws of electricity are as well known at present as they will be in the future, but I do think that the laws are absolute, and that when the conditions are the same the results will be the same, whether certain experiments are tried in Virginia or Massachusetts, and later on, I propose to quote the opinions of some well-known electrical scientists in order to re-enforce my opinion. In further reference to the so-called McCluer system, it may be of interest to state that it has been fully tried in the neighboring city of Cambridge in order to ascertain whether by its means the telephone service, which had been seriously interfered with by conduction and induction from a *grounded* high tension circuit, might be restored to its previous state of efficiency. We carried out the plan faithfully and at great expense. The results were not and are not satisfactory. The troubles caused by conduction which, in addition to producing an ear-splitting noise on the lines, also threw the drops in the central station, were, as far as the latter point is concerned, mainly gotten rid of, but the effect on induction troubles was virtually nil.

Personal interviews with, perhaps, 100 subscribers and balancing the opinions as to whether or not they had perceived any difference in the working of their telephones, forced us to the conclusion that, from an unbiased standpoint, we had not netted any great returns for our expenditure. I do not know of any reason why we should; theory and practice do not alwaye jibe.

As intimated above, I give, for your information, some statements and opinions of other men concerning the effect of high tension currents on the telephone, and other matters in this connection.

First, Mr. Preece, of the British Government telegraph system, when writing "On Induction Between Wire and Wire," says:

"Last year, at Birmingham, I pointed out that the electromagnetic induction between wire and wire upon lines of telegraph extended to distances much greater than was anticipated, and that effects were observed even when the wires were separated by the breadth of England. In all the following experiments the primary currents were always of rapid frequency, producing a buzzing sound, which could be easily read when audible, if sent in the Morse code and received on a Bell telephone. No difference whatever could be detected in the strength of the signals received by induction, whether the space was air or water, or a combination of air and water.

"I joined a telephone to the ends of two cables, one terminating at Lisbon, 820 miles away, the other one terminating at Vigo, 620 miles away. Signals could be distinctly heard on the telephone from the Brest cable landing, about half a mile away, and terminating at Penzance. The disturbances due to the mixed working currents on our telegraphs cannot be appreciable beyond 450 feet, but those employed in distributing electric light by means of secondary generators must extend to miles, unless they are neutralized by the two conductors being fixed parallel and close to each other."

Writing later "On Disturbances Arising from the Use of Earth for Electric Lighting Purposes," Mr. Preece says: "The magnetic field produced by a current flowing in a straight wire and returning through the earth, extends to such distances that it is quite impossible to say where, or when, or how a telephone circuit in that field would be disturbed by any changes in that current. It is quite certain that if a single conductor between Deptford and London were subject to rapid alternations under a potential difference of 10,000 volts—the current returning by way of the earth—every telephone circuit in the metropolis would be disturbed and probably rendered unworkable."

After quoting from a paper read by him before the British Association, stating the law determining the distance to which this influence extends, Mr. Preece proceeds to say that:

"It follows from this formula that currents of rapid frequency on a conductor of ten miles in length, carrying 100 amperes, might be evident at a distance of nineteen miles. It becomes, therefore, important to decide to what extent disturbing influences can be eliminated. It is well known that if either the disturbing circuit or that disturbed be constructed of two wires so close to each other and so erected that the mean average distance between the disturber and the disturbed is the same, no inductive effects are evident, for the influence on one wire is entirely neutralized by the equal and opposite effect on the other. But if this mean average distance is not equal, or if the equality of the two currents be departed from, then a disturbance will arise which will depend on the difference between the two currents and their relative distances. Hence the most perfectly silent telephone circuit becomes noisy when leaks occur in the insulation, and hence it is that the earth plays such an important part in the efficiency of the system."

Writing on "Problems in Electric Traction," Dr. Louis Bell says:—

"The effect of a traction line on all neighboring telephone lines is very marked, in some cases rendering them almost useless. The exact nature of the phenomena produced is very complicated. Listening at a telephone thus affected, it is possible to follow in considerable detail the operation of the motors. Whenever a car is started, a low hum is heard, gradually rising in intensity and pitch as the speed increases, and as the connections are shifted from step to step on the switch box. Beneath this distinct note is a confused whirring sound of lower pitch and greater intensity. The effects are clearly due to the superposition of several different periodic variations in the current and E. M. F. on the traction line. The transference of this disturbance to the telephone line depends on two quite distinct causes; first, the direct effect of induction, and second, the disturbance due to the fact that both systems are grounded at points not very far distant from each other. The relative importance of these two causes varies very widely in different places. Here (Lafayette, Ind.), most of the trouble comes from direct induction, while it is not uncommon to find nearly all of it coming from the grounds. Both causes must in general be eliminated to avoid the difficulty. But in very many cases it is desirable to use the single overhead wire, and some simple means of avoiding at once earth and induction is desirable. Clearly it is not sufficient to use the track alone for a return, or the track with an auxiliary wire beside it, as is quite usual. For the current of supply is, or always should be, divided between the trolley wire and a line wire connected with it at intervals; hence the inductive effect of this overhead system can never be balanced by an equal current along the ground by reason of unequal distance from the overhead telephone wires."

In an article lately published by Mr. Nelson W. Perry, of Ohio, he quotes some published opinions of Mr. Sprague's, of the Sprague Electric Railway Co., and in reply thereto says:—

"One thing I found out, and that is that it is not safe to generalize as Mr. Sprague has done. We cannot say that in one case either induction or conduction will be the predominating disturbing element until we have actually tested the case in question. This is so, not because the nature of the laws governing induction are imperfectly understood, but because there may be many modifying causes that cannot certainly be predetermined either as to their existence or extent.

---

[1] Abstract of a paper read before the Boston Electric Club.

"Now the McCluer device is one by which it is sought to remove the telephone ground to a point so far removed from the seat of disturbance that conduction currents cannot enter upon the telephone lines. It is not claimed by Mr. McCluer, nor is there any theoretical reason whatever for claiming, that the McCluer device can, or will, abate in any way disturbances due only to induction.

"A telephone subscriber located at a considerable distance, say a mile or two, from the electric railroad, will, if his telephone have a ground at that point, enjoy the fullest benefits of the McCluer device. As many of the telephone lines running parallel with the electric railroad extended to this distance, and in some cases to much greater distances from the line of the railway, and were still exceedingly noisy, I thought it not worth the while to attempt an experiment with a specially prepared McCluer wire. In fact, as four of the wires extended to a distance of not less than 17 miles beyond the terminus of the railroad and were still exceedingly noisy, I would have had to go a long distance indeed to have found a better point to ground my wire. It was proof conclusive that the McCluer device would do no good in that particular case. I also demonstrated another point that I did not know before, but which, it seems, was known to others more familiar with the subject than I, and which afterward came out in the expert testimony at the trial, viz., that two quiet circuits, when united into one, may become quite noisy.

"But I was very much mystified by the difference in degree to which telephones seemingly similarly situated were affected. Every rule and probability seemed to be set at defiance. As I have said, some telephones, whose grounds were furthest removed from the railroad, were noisier than some whose grounds were nearer to it. A telephone whose wire ran parallel with the road for a quarter of a mile was sometimes noisier than one whose wire ran parallel for half a mile; but what was more perplexing, it was not always the case. Two telephones, whose wires were parallel for equal distances, were usually affected to perceptibly and often markedly different degrees. Sometimes, of two telephones leaving the street at the same pole, the one going east was the worse; at others that going to the west gave most trouble. Sometimes it was the one that ran into low ground that responded the loudest.

"Mr. Sprague argues that the induction cannot become prominent because the wires are not nearer than from 20 to 30 or 40 feet, and seldom parallel for distances greater than two or three miles. One of my experiments shows that if they are parallel for half a mile at this distance, the disturbance is quite marked. And furthermore there are several patents that have met with more or less success experimentally for telegraphing to and from moving trains. This is accomplished in exactly the same way as the telephonic troubles under discussion are caused, and in such appliances of the principle and induction the length of parallelism is not two or three miles, but limited to the length of a single railroad car, or at most to the length of a railroad train.

"Mr. Sprague furthermore says: 'The current used upon this wire (the trolley wire), is not of the character which distinguishes some of the arc light circuits, but is of more or less even flow, and the abrupt and large changes due to the change of load on the motor are comparatively infrequent. There is a very small change due to the variation of resistance of the armature of the motor, because of the different relative positions of the commutator blocks under the brushes, and there is likewise a variation due to the slight but rapid changes of counter electromotive force set up by the motor when running.'"

Mr. Perry in reply says: "Variations in current due to such cases is many times too slow to produce an audible sound, but I do not think it is largely due to the very rapid and inevitable changes of current due to the varying contact between the wheel and the dirty track over which it is rapidly moving, and, in case the electrical connection between the motor and the track be by means of the gear, by the unavoidable variation of contacts between these parts."

As we have dwelt at considerable length on the difficulties to which the telephone is subjected in consequence of its sensitiveness and adaptability for picking up extraneous sounds which are not at all desirable or necessary in the proper transaction of the business, it may be well to point out, if possible, what might be done towards eliminating these troubles. It is easy to say the telephone people should use metallic circuits; much easier to say, than it is to do it. A real good metallic circuit for telephonic use can be made by twisting two insulated copper wires together. I do not know of anything that will equal in efficiency this plan. It is very evident that this copper wire needs some extra protection, and that is obtained generally by using a lead pipe to encase the cables made up of copper wires. This arrangement will do very well when laid in underground conduits, or, as has been done in a few instances, by making up a light weight cable and suspending it from poles; but it is utterly impracticable to use cables or twisted copper wires in all cases. Underground wires must connect at some point with overhead wires, and regarding the working of wires underground Mr. J. J. Carty in his very able paper recently read before the New York Electric Club says:

"This putting wires underground in cities is the only bar to a universal system of telephony, and if direct air lines were built, New York and Chicago would be placed within speaking distance of each other at once. To place telephone wires underground and maintain the same efficiency as in overhead lines, would require an insulation on each wire of over two feet in thickness, and instead of getting 50 pairs of wires into a three-inch pipe, as at present, a tunnel occupying half the street would be required for one cable alone. When we consider that a telephone office of even moderate size would require about a hundred such gigantic cables, it is seen how almost hopeless the case becomes."

Lastly, in addition to the fact that in order to obtain the very best results, not only are the twisted wires a necessity, but a balance must be maintained between each side of the metallic circuit, and the insulation should be as good on one side as on the other. A loss of insulation will certainly result in a noisy circuit.

Now, leaving out of consideration altogether the points of dispute as to which interest, if any, should own the earth, or as to whether this line, or that line, was the first comer, we can think of what, in a general way, may be a cure for the induction and conduction disease.

And as we have dwelt upon what might be done by making the telephone wires up in metallic circuit, we can also point out some other way. Low tension wires and high tension wires should be separated from each other as much as possible. I think there can be no dispute about that. Telephone wires should be placed on one side of the street and high tension wires on the opposite side of the street, if no greater distance can be attained. The main troubles arising from conduction will manifestly be gotten rid of in this way. The probable interference from induction still remains to some extent. That, however, can be materially lessened by having both sides of each high tension circuit placed as near to each other as is practicable, and with frequent transpositions of each circuit—the placing of lamps on each side in order to preserve as nearly as is possible an electrical balance, and carrying in a loop both sides of the circuit on which lamps are to be placed on a street, and not on the direct line—will certainly tend to lessen the troubles under which the telephone labors. I do not know that it is necessary to dwell upon what might be done with grounded circuits carrying a high tension current, except to say that there are good reasons why there should not be any such circuits.

THE KANSAS STATE ELECTRIC ASSOCIATION.

A meeting of the representatives of the various electric light companies doing business in Kansas, was held at Topeka, and organized a state association of central station companies under the name of the Kansas State Electric Association, to promote the legitimate growth of the business; the securing of uniformity in regulations for inspection of construction and inside wiring; also underwriters' rules for insurances, and to give such assistance and advice to the companies in its membership as may be consistent with the general interests of the industry and the benefit of consumers. The following officers were elected: President, L. A. Beebe, Hutchinson; vice-president, G. F. Parmelee, Topeka; second vice-president, J. C. Fuller, Winfield; secretary and treasurer, R. C. Johnston, Lawrence.

MANUFACTURE OF PROJECTILES BY ELECTRIC WELDING.

ANOTHER of the many uses to which electric welding can be put, has been prominently brought forward in the shape of rumors well founded that the Thomson Electric Welding Co. would commence the manufacture of projectiles by the welding process.

It has heretofore been remarked that the Thomson Electric Welding Co. had taken out patents which might form the basis for the organization of a new welding company, but particulars have not until now been accessible. It appears that about four months since Lieutenant W. M. Wood of the United States navy, who is on leave of absence, and associated with the Thomson Welding Co., conceived the idea of manufacturing projectiles by the electric welding process, with a view to secure better results than have been heretofore obtained by any other process, and at a saving of expense. The idea was wrought out, and patents for this purpose have been granted. Heretofore the government has had to bore solid metal at great cost. By the process as governed by the patents a steel tube of the proper length and thickness is welded to the head and then to the butt of the shell, thus in a few moments accomplishing what now requires hours of costly machine labor. The process is varied according to the class of shell or shrapnel to be manufactured, all details of which are covered by the patents which the company holds.

The Thomson Electric Welding Co. has taken out similar patents in all foreign countries, and that department will receive attention later. The old, or parent, electric welding company is arranging to supply welding plants at the navy yards in Brooklyn, Norfolk and Washington, and a dispatch reports that an item of $12,000 has been reported to the House by the naval committee in the appropriation bill for a chain welding plant for the Charlestown Navy Yard.

THE STANDARD TYPE OF ELECTRIC LIGHT AND POWER STATION.

The Electric Mutual Insurance Co. has now been formed in Boston, with the following officers: Stephen E. Barton, *president;* Everett W. Burdett, *vice-president;* Herbert H. Fairbanks, *secretary and treasurer;* William Brophy, *chief inspector*. The *directors* are, F. A. Gilbert, president Boston Electric Light Co., Boston; C. L. Edgar, manager Edison Electric Illuminating Co., Boston; E. W. Burdett, treasurer Citizens' Electric Light Co., East Boston; General Benjamin F. Peach, Jr., assistant treasurer Thomson-Houston Electric Co.. Boston; T. C. Bates, director Worcester Electric Light Co., Worcester; Elisha Morgan, president United Electric Light Co., Springfield; Robert B. Taber, manager New Bedford Gas Light Co., New Bedford; Thomas T. Robinson, contractor, president and director of several electric light companies, Boston; Stephen E. Barton, Boston; William Brophy, Worcester.

The requirements of the company for the construction, equipment and maintenance of a standard electric light or power station, are:—

CONSTRUCTION OF BUILDING:

Material of Walls.—It should be built of brick, or other fire-proof material, and not over two stories high. A wire tower, or basement will not be regarded as a story.

Material of Roof.—The roof should be covered with metal, slate, composition, tar and gravel, or other non-inflammable material, and the cornice should be brick, metal, or open and plain. Boxed or cased wooden cornices are undesirable.

Wooden sheathing should not be placed on roof timbers or rafters so as to leave concealed space, and vacant attics should be avoided. With either pitch or flat roofs, it is desirable that no attic or blind space be left.

Material of Floors.—The floors (if not made of some fire-proof material) should be at least three inches thick, preferably of two or three-inch plank, grooved and splinted, with one-inch jointed hardwood for a top flooring. Maple, birch, beech, or hard-pine are desirable for the "top flooring," as they do not readily absorb oil. If the station is more than one story high, the floors above the ground floor should be free from all openings, if possible, in order that a fire originating on one floor would not readily communicate to another through the openings in floors.

Stairs and Elevators.—Stairs and elevators should be placed outside, where possible, or if inside the building, stairs should be completely partitioned off from the room below, with some hardwood or other slow-burning material, and provided with self-closing doors hung at the bottom of the flight. Elevators should not be cased up but should be provided with approved, self-closing hatches.

Inside Finish.—There should be *no* inside finish such as sheathing, lath and plaster, or any finish that would leave concealed spaces between outer and inner walls, or add inflammable material to the station. If the building is of brick, the inside should be left perfectly plain, being finished with paint if necessary to cover the roughness. If constructed of wood, the timbers and boarding should be dressed on the inside if a rough finish is undesirable. But by all means the inside walls and ceiling should be left plain and open, sacrficing beauty for safety, always.

Boiler-House.—Boilers and boiler chimney should be cut off from the engine and dynamo-rooms by a fire-wall (not less than eight inches if brick, and thicker according to the character of building) with as few openings or communications as possible, and such openings should be protected with heavy, tin-clad doors (or shutters, if windows). The cut-off wall should extend high enough between the boiler-room and engine or dynamo-room to effectually stop communication of fire between them.

No wood should be in contact with any part of the boiler-setting, and roof or floor should be three feet or more from boilers.

Fire-Doors and Shutters.—An approved fire-door or shutter is made of two thicknesses of one-inch matched boards, a layer of asbestos between boards, and nailed together with clinch-nails. The boards should run diagonally, the two sides in opposite directions, to give strength. The covering should be with "I–C" tin, 14x20, laid on with flat lock, securely nailed under the lap, the covering to commence at the edge of the door, and "locked in" to the centre of the side of the door. Both sides and the edges should be covered, and great care taken that all joints lock. Sheet tin should be used, and *not* sheet iron, the latter being too heavy to allow of lock jointing. The doors or shutters should be hung with substantial hinges, preferably wrought iron, bolted through the door and equally as securely fastened to the door-frame or building. The frame, or casing of the door, should be as securely tin-clad as the door. The door, or shutter, should be provided with a strong latch to hold it firmly in place.

Doors should be self-closing to insure their being kept shut. If *necessary* to have them open for ventilation or other purpose, they should still be provided with the self-closing apparatus, but held open by a long hook, or stay, made in two sections and joined together by a soft solder that will yield at a temperature of 150 degrees Fahr., and allow the door to automatically close, or by some similar arrangement.

Whether fire originates in the boiler-room or the engine and dynamo-room, the efficient fire-wall is valuable in saving from injury either the one or the other, and thereby lessening the delay and loss incident to a destruction of the whole plant.

Chimney and Iron Stack.—If the chimney is of brick, it should never be less than two bricks thick, with air-space, and should be free from contact with wood, where possible.

If an iron stack is used, and it goes through a wooden roof (or floor), the wood should be cut away at least one foot all around, and a metal collar placed over the opening. This collar should not come within three or four inches of the iron stack, but should be turned up on the inside edge, flange-like, around the stack. Above the collar should be placed a hood sufficiently wide to prevent storms from beating in.

Such an arrangement will, in addition to being safe, serve as a good ventilator for the boiler-room.

Automatic Sprinklers in Lieu of Fire-Wall.—Where a fire-wall, as above described, is impracticable or undesirable for any reason, an approved equipment of automatic sprinklers thoroughly covering the area of the boiler-room will be accepted in lieu of such fire-wall. The pipe supplying the sprinklers must be of sufficient size to adequately supply all of the automatic heads at one time, upon the assumption that such an emergency may arise, The water supplying the pipes must come from some water-works, or other gravity source with sufficient head and supply to give a satisfactory pressure and quantity.

The gate-valve admitting the water to the sprinkler pipes should be securely fastened *open*, and sealed to insure its being *always open*. An auxiliary supply to the sprinklers should be provided by attaching the boiler feed-pump, or any other forcing pump of sufficient capacity, on the premises; the pump to be used in case the gravity supply should happen to be shut off when needed.

(Specific information in relation to sprinklers and supply will be given if called for.)

ELECTRICAL EQUIPMENT.

Insulation of Dynamos.—All electric generators should be well insulated on dry floors, or dry wood base frames, and if the latter, they should be well painted in order that they may not absorb moisture or oil, and they should at all times be kept free from oil by frequent wiping. Dynamos should be provided with water-proof covers, to be kept on them when not running.

Wiring.—All wiring from dynamos, generators, or exciters, to switch-boards, rheostats, or instruments and devices of any nature, and from thence to outside lines, should be run in *plain sight* and wholly on non-combustible insulators such as glass, or porcelain, or on hard rubber hooks. Where any wires pass through wood (either floors, partitions, or walls), they should be absolutely free from contact with the wood by the use of non-combustible, or non-inflammable insulating tubes, such as glass "floor insulators"; wooden cleats should never be used in a station.

Separation of Wires.—Wires of opposite polarity, or the same polarity where any great difference of potential exists, should be rigidly kept apart sufficient distance to preclude the possibility of their coming in contact.

'Bus Bars.—'Bus wires, or bars, and all connections thereto, should be ample in carrying capacity to prevent heating under any normal conditions, and they should be supported on non-combustible insulators, absolutely free from contact with wood or other inflammable material.

Connections, Splices.—All wire connections or splices should be equal in carrying capacity to the wire itself, and they should be soldered if necessary to secure permanent good contact and conductivity.

Wires Under Floors.—Where possible it is preferred that wires should be run from dynamos directly up to proper insulators overhead, rather than down, through the floor and up again to switchboards, etc. If it should be impossible to avoid running them down through the floor, the best of insulation, that will not yield to the solvent action of oil, and also glass floor insulators must be used. The space under the floor should be ample to admit of easy examination and good ventilation, and the wire must be specially insulated and run on non-combustible insulating supports.

Switch-Boards.—All switch boards should be set out from the walls or partitions, so that free access can be had all around them. They should be made of non-combustible material, such as slate or the like; or, if made of wood, they should be "skeleton" in form, and of oak, hard pine, or other slow burning wood. They should never be built in compact, solid form, extending from floor to ceiling, but should be in such form that no arc or fire could occur without being discernible from any part of the room.

All wiring on the switch-board (if of wood) should be on glass or porcelain.

Rheostats.—Unless the case or frame surrounding rheostats, or similar instruments, is made of non-inflammable material, they should be set out from the woodwork by placing porcelain knobs, or the like, behind them.

It is preferable that all such devices be placed on the switch-board, or on non-combustible walls.

Feeder Equalizers.—The frames of feeder equalizers should be of iron or other non-combustible material, and they should be set at least one foot from any wood or other inflammable material. Where they are grouped together, or cannot readily be arranged as provided above, they should be separated by asbestos or cement from wooden floors or walls, and at once protected by a sufficient number of automatic sprinkler heads with gravity supply of water constantly on them.

Wire Tower.—If a tower is used for wires entering the station, it should be easy of access for inspection, sufficiently large to prevent crowding and dangerous crossing of wires, and the wiring should be only on non-combustible insulators; glass, or other equally good, non-inflammable insulating tubing to be used where wires pass through the sides.

Lightning Arresters.—Both sides of every circuit should be provided with lightning arresters, placed in some location in plain sight, preferably on the switch-board away from woodwork. The ground wire should be of large size. A "saw-tooth" arrester should not be used on any circuit of over 125 volts.

All arresters for currents of over 125 volts should be so constructed as to instantly break the arc after the discharge has passed off.

FIRE APPARATUS.

Gravity Supply of Water.—Every station should be supplied with water from some gravity source, such as public water-works, or a tank with not less than 2,500 gallons, elevated enough to furnish pressure necessary to reach any part of the building.

Size of Pipe.—The outlet pipe from the water-works or tank to the hydrants should not be less than two inches in diameter, and larger according to the size of the station.

Hydrants.—If the engine and dynamo room are separated from the boiler-room by fire-wall and fire-doors, there should be a hydrant on each side of the wall, located at some accessible point where it would command all parts of each room and could be readily reached and controlled from the inside or outside.

Hose.—The hose on these inside hydrants should not be larger than 1½ inch diameter, and need not be larger than 1 inch. Hose of small size can be more quickly and easily handled by one person. It should be the best in quality, say cotton woven and rubber lined, and should be constantly attached to the hydrant, and kept on a proper shelf or hose rack, lapped one fold upon another so that it can be taken off without twist or kink. It should never be coiled up, except the coil is started at the middle of the length, so that the two ends will be together; otherwise when uncoiled it will contain a twist for every convolution. The hose at each hydrant should be of sufficient length to reach all parts of the rooms it is designed to protect, but not so long as to be cumbersome. It is well to have an extra length or two in reserve.

Nozzles.—The nozzle should be small at the delivery end, not over one-half or three-eighths inch, in order to give greater pressure, and there should be no cock or valve in it, as they are liable to stick from corrosion and other cause.

Valves.—The valve for letting on water should be at the hydrant where the hose is kept attached, and it should be occasionally tried to see that it works freely.

Secondary Supply of Water.—As an auxiliary water supply, the hydrants should be connected with the most powerful forcing pump on the premises, by a pipe of the full capacity of the pump or of the hydrants. Public water sometimes gets shut off, or its pressure becomes reduced, and tanks or other sources may become exhausted; therefore it is important to have pumps attached to hydrants.

Tell-tale for Tanks.—If a tank is used, a "tell-tale" should be arranged to indicate to the proper person when the water becomes lowered by evaporation or otherwise.

Fire-pails.—Each floor must be provided with not less than three fire-pails (and more if a large room), which should be constantly filled with water unless a supply is on hand in the room, such as from faucets in sink, or barrels kept full. The pails should be of galvanized iron, fibre, or some similar material that will not shrink and become unserviceable in time, and they should be kept exclusively as fire-pails.

Fire Extinguishers.—In the absence of a gravity supply of water, the inside hydrants must be supplied from the boiler pump, or other forcing pump, and the station should be supplied with two or more fire extinguishers, similar to the modern "Babcock Pony Extinguisher."

Outside Protection.—If the station is located in a town having a Fire Department with water-works or steamers, or both, a special hydrant (if water-works) should be secured and set within 200 feet of the building, unless there exists one within that distance. If the service consists of a steamer or steamers without water-works, a reservoir or other supply for the steamer should be located within the distance above named.

Fire-Alarm.—If there exists an electric fire-alarm system in the place, a special box should be secured and located at the station, unless there is one within a couple of minutes' reach, and a key (unless it is a keyless box) should be kept at the station. In the absence of any electric fire-alarm system, a signal, such as blowing the whistle, should be agreed upon with the Fire Department in order that a call for help may be quickly responded to.

Exposures.—If there are other exposing buildings or hazards within 50 feet, the station should be protected by tin-covered shutters at the windows or other openings on the exposed sides, if it is built of brick or has other fire-proof walls. If the station is built of wood, the exposure may sometimes be reduced by running a line of open sprinkler-heads along the top of the exposed side; the pipe supplying the heads to be of ample size to give them all full pressure at once, and it should be connected to some gravity source of water or force-pump, with a valve to open and let on the supply in case of fire in the exposing building.

Dwellings will not, ordinarily, be regarded as exposures.

CARE AND ATTENDANCE.

Attendance.—The station should not be left alone any considerable time, and a competent man should be kept constantly in the dynamo and engine rooms when in operation.

Oily Floors.—As oil has been the most prolific cause of the spread of fires and the consequent serious damage in electric stations, it will be required that the floors and machines be kept as free as possible from the accumulation of it on them.

Washing Floors Weekly.—If dynamos are properly insulated on dry, painted wooden base frames, and if the wiring is properly done by carrying conductors up direct from the dynamos to insulators overhead, it will be quite safe to wash the floors every week, and thereby keep them free from oil. Washing may be safefy done where wires pass down through the floors, if good water-proof insulation and glass-floor insulators are used.

No wire should ever be laid *in* the floor, or under moulding or boxing on the floor.

Waste.—Oily waste should be carefully deposited in metal waste cans, kept in the engine and dynamo room for that purpose. It should never be laid on the floor, or in wooden boxes.

Oil-room.—Oil tanks should be kept in a room with cement or other non-absorbent and non-inflammable floor, or should be provided with metal pans under them, and any accumulation of open oil in pans or about the station should be avoided.

NOTE.

After every precaution has been taken to avoid fires happening, it must be conceded that they are liable to happen; and the aim of this Company is, to reduce the chances of such accidents, by approved construction of the building and safe electrical installation, and then, recognizing the fact of the inevitable fire, to have the station kept as free as possible from inflammable substances, particularly as to oil around engines and dynamos, and so equipped with ready and efficient fire-extinguishing apparatus that the least possible damage will be done. If everthing fails, and the station is destroyed, it should be fully insured, but, by neglecting precautionary measures the price of full insurance is so large as to preclude it. If it can be secured at *cost* after all precautions are taken, it should be carried by every station-owner.

LAND LINES AND LIGHTNING.

The *Journal Télégraphique*, of Berne, gives a table showing the various accidents which occurred to telegraph lines during the year 1888. From this list we take the casualities due to lightning in the undermentioned countries.

	Percentage of Casualities to		
Countries.	Posts.	Insulators.	Instruments.
Belgium	0·071	0·004	0·315
Denmark	0·035	0·009	1·491
France	0·070	0·019	0·675
Germany	0·055	0·001	1·613
Holland	0·071	0·011	1·851
Italy	0·220	0·042	2·222
Switzerland	0·035	0·005	3·030

It will be noticed that lightning damaged the greatest number of posts and insulators in Italy, and by far the greatest number of instruments in Switzerland. The least damage was caused to posts in Denmark and Switzerland, to insulators in Germany, and to instruments in Belgium.

MAGNETISM.

BY DR. JOHN HOPKINSON, F.R.S.

(Continued from p. 219.)

In speaking of the properties of bodies which, like manganese steel, are slightly magnetic, it may be well to enter here a caution. But little that is instructive is to be learned by testing filings, or the like, with magnets, as these show but little difference between bodies which are slightly magnetic and those which are strongly magnetic. Suppose the filings to be spheres, in the following table are given comparative values of the forces they would experience in terms of μ, if placed in a magnetic field of given value, μ having its ordinary signification—that is, being the ratio of the kick on the galvanometer when a ring is made of the material of the filing, to the kick if the ring is made of a perfectly non-magnetic material:

μ.	Attraction.	
1	0	Non-magnetic body.
1.47	0.18	Manganese steel with 12 per cent.
3.6	1.2	Manganese steel with 9 per cent.
5	1.5	
10	2.1	
100	2.8	
1,000	2.98	

Now bodies in which μ is so small as 3.6 belong distinctly to the non-magnetic class; but the test with the magnet would very markedly distinguish them from manganese steel with 12 per cent. of manganese. The distinction, however, between $\mu = 3.6$ and $\mu = 1,000$ is comparatively small; whereas, under the conditions of experiment, μ is much more than 1,000 for most bodies of which iron is the principal constituent.

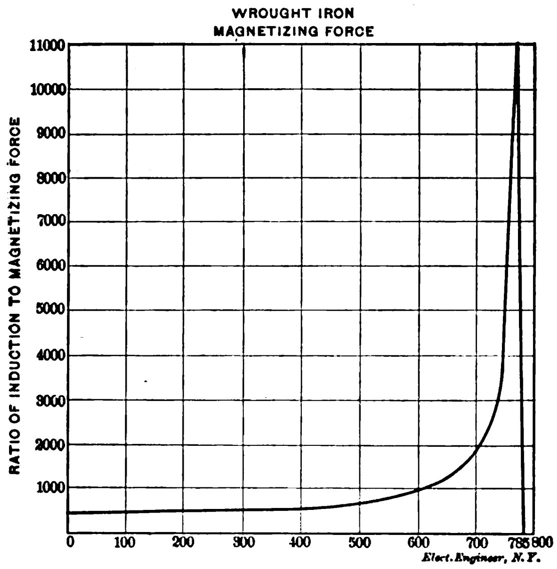

FIG. 8.

The effect of stress on the magnetic properties of iron and nickel have been studied by Sir W. Thomson. A fact interesting from a broad and general point of view is that the effects of stress are different in kind in the case of iron and nickel. In the case of iron, for small magnetizing forces in the direction of the tension, tension increases the magnetization; for large forces, diminishes it. In the case of nickel the effect is always to diminish the magnetization.

When one considers that the magnetic property is peculiar to three substances—that it is easily destroyed by the admixture of some foreign body, as manganese—one would naturally expect that its existence would depend also on the temperature of the body. This is found to be the case. It has long been known that iron remains magnetic to a red heat, and that then it somewhat suddenly ceases to be magnetic, and remains at a higher temperature non-magnetic. It has long been known that the same thing happens with cobalt, the temperature of change, however, being higher; and with nickel, the temperature being lower. The magnetic characteristics of iron at a high temperature are interesting. Let us return to our ring, and let us suppose that the coils are insulated with a refractory material, such as asbestos paper, and that the ring is made of the best soft iron. We are now in a position to heat the ring to a high temperature, and to experiment upon it at high temperatures in exactly the same way as before. The temperature can be approximately determined by the resistance of one of the copper coils. Suppose, first, that the current in the primary circuit which we use for magnetizing the ring is small; that from time to time, as the ring is heated and the temperature rises, an experiment is made by reversing the current in the primary circuit and observing the deflection of the galvanometer needle.

At the ordinary temperature of the air the deflection is comparatively small; as the temperature increases the deflection also increases, but slowly at first; when the temperature, however, reaches something like 600° C., the galvanometer deflection begins very rapidly to increase, until, with a temperature of 770° C., it attains a value of no less than 11,000 times as great as the deflection would be if the ring had been made of glass or copper, and the same exciting current had been used. Of course a direct comparison of 11,000 to 1 cannot be made; to make it we must introduce resistance into the secondary circuit when the iron is used; and we must, in fact, make use of larger currents when copper is used. However, the ratio of the induction in the case of iron to that in the case of copper, at 770° C., for small forces is no less than 11,000 to 1. Now mark what happens. The temperature rises another 15° C.; the deflection of the needle suddenly drops to a value which we must regard as infinitesimal in comparison to that which it had at a temperature of 770° C.; in fact, at the higher temperature of 785° C. the deflection of the galvanometer with iron is to that with copper at a ratio not exceeding that of 1.14 to 1. Here, then, we have a most remarkable fact: at a temperature of 770° C. the magnetization of iron 11,000 times as great as that of non-magnetic substance; at a temperature of 785° C. iron is practically non-magnetic. These changes are shown in Fig. 8. Suppose now that the current in the primary circuit which serves to magnetize the iron had been great instead of very small, In this case we find a very different order of phenomena. As the temperature rises the deflection on the galvanometer diminishes very slowly till a high temperature is attained; then the rate of decrease is accelerated until, as the temperature at which the sudden change occurred for small forces is reached, the rate of diminution becomes very rapid indeed, until, finally, the magnetism of the iron disappears at the same time as for small forces. Instead of following the magnetization with constant forces for varying temperatures, we may trace the curve of magnetization for varying forces with any temperature we please. Such curves are given in Figs. 9 and 10. In the one diagram, for the purpose of bringing out different points in the curve, the scale of abscissæ is 20 times as great as in the other. You will observe that the effect of rise of temperature is to diminish the maximum magnetization of which the body is capable, slowly at first, and rapidly at the end. It is also very greatly to diminish the coercive force, or to increase the facility with which the body is magnetized. To give an idea of the magnetizing forces in question, the force for Fig. 8 was 0.3; and as you see from Figs. 9 and 10, the force ranges as high as 60. Now the earth's force in these latitudes is 0.43, and the horizontal component of the earth's force is 0.18. In the field of a dynamo machine the force is often more than 7,000. In addition to the general characteristics of the curve of magnetization, a very interesting, and, as I take it, a very important, fact comes out. I have already stated that if the ring be submitted to a great current in one direction, which current is afterwards gradually reduced to zero, the ring is not in its non-magnetic condition, but that it is, in fact, strongly magnetized. Suppose now we heat the ring, whilst under the influence of a strong magnetizing current, beyond the critical temperature at which it ceases to have any magnetic properties, and that then we reduce the current to zero, we may in this state try any experiment we please. Reversing the current on the ring, we shall find that it is in all cases non-magnetic. Suppose next that we allow the ring to cool without any current in the primary, when cold we find that the ring is

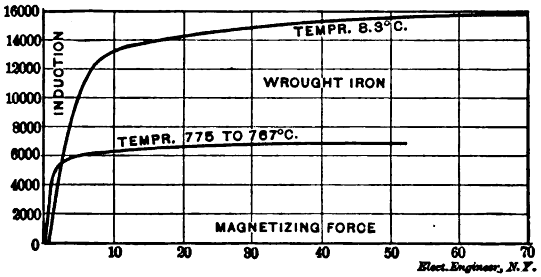

FIG. 9.

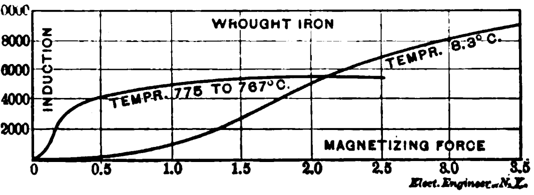

FIG. 10.

magnetized; in fact, it has a distinct recollection of what had been done to it before it was heated to the temperature at which it ceased to be magnetic. When steel is tried in the same way with varying temperatures, a similar sequence of phenomena is observed; but for small forces the permeability rises to a lower maximum, and its rise is less rapid. The critical temperature at which magnetism disappears changes rapidly with the composition of the steel. For very soft charcoal iron wire the critical temperature is as high as 880° C.; for hard Whitworth steel it is 690° C. (*To be continued.*)

THE NEW DAFT ROAD AT SUNBURY, PA.

The Daft Electric Light Co., of 115 Broadway, have recently completed a most interesting electric railway installation for the Sunbury and Northumberland Street Railway Co. This road, which is to be operated on the overhead system, crosses a bridge a mile long across the Susquehanna river, and the Reading and Lehigh Valley Railroads have contracted with the electric road for the transfer of expressage, passengers, etc. The track is well built, having been laid with Johnson girder rail, and a speed of 25 miles an hour will be made. Three trains of cars will be run. The motor cars are equipped with the 30 h. p. individual motors which the Daft company have adopted as their standard. The power plant has been equipped in duplicate, in engine units of 125 h. p. each, with generator capacity to correspond. Altogether the road is a striking piece of work, and it is attracting considerable attention.

A LIST OF THOMSON-HOUSTON ELECTRIC RAILWAYS.

THROUGH the courtesy of the Thomson-Houston Electric Co., we are enabled to print a complete list of their electric roads up to April 1.

ROADS IN OPERATION.

December 15th, 1889	528	335.75	49
April 1st, 1890	665	463 56	61
Increase	137	127.81	12

The grand total of roads built and under contract is 100 roads 1,096 cars and 848.76 miles of track.

The company have also received "repeat" orders as follows from roads in operation: Second Avenue Passenger Railway, Pittsburgh, 10 motors; Bangor, Me., Street Railway Co., 10 motors; Central Railway Co., Peoria, Ill., 12 motors; Des Moines, Ia., Electric Railway Co., 20 motors; Denver, Col., Tramway Co., 4 motors.

... IF I can succeed in working a magnet ten miles I can go round the globe.—*Prof. Morse.*

.... THERE is a proper curiosity in knowing the possible influences which produced a man on whose brow fame has, with much apparent fondness, rested her decorating hand.—*Hon. James D. Reid.*

.... THE electric telegraph as it exists to-day was of slow and gradual growth—so slow and gradual that it is impossible to point to any one man as being the inventor of telegraphy.—*G. W. de Tunzelmann.*

.... ELECTRICITY as a science is susceptible of great powers to stimulate and delight. Its demonstrations are, unique, startling, brilliant. No branch of experimental philosophy is so full of pictures, so replete with surprise.—*Hon. James D. Reid.*

....SINCE the use of gas has become so general in our cities as to be considered almost one of the essentials of civilized life, a new source of danger has been introduced. Persons who repudiate the use of lightning rods because they attract the electricity from the clouds, should reject the introduction of gas—particularly in the upper stories of their dwellings, since the perpendicular pipes must act as the most efficient conductors between the clouds and the earth.—*Joseph Henry.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

The New Subway Work.—The Edison Exhibition.—The Edison-Gilliland Phonograph Suit.

AT the last meeting of the Board of Electrical Control, the Standard Subway Co. withdrew from the contest to obtain a share of the subway building, and the Board has now given orders to the old Consolidated Company to proceed with the work. The plans now approved cover a large number of streets and will require, it is said, about two years to be carried out.

The Edison exhibition at the Lenox Lyceum, Madison avenue and Fifty-ninth street, for the benefit of the New York Exchange for Women's Work, draws delighted audiences every afternoon and evening. The phonograph exhibition is truly wonderful. The electric lighting apparatus, the talking dolls, the telephone combinations, and a score of ingenious and wonderful things are to be seen and heard there during the whole of the present month. Over $5,000 has already been received by the lady managers, for season tickets alone.

Mr. Luther Stieringer is very much to be congratulated upon the success, immediate and pronounced, that he has won with the "Tower of Light," and which, with the help of Messrs. Seubel and Meadowcroft, he built from his original designs in one short week. It is an immense column, gracefully proportioned, in the centre of the hall, eight feet in diameter and twenty five feet high, with 3,000 to 4,000 small Edison white and colored lamps running spirally around it from the base to the capital, on which are massed a number of larger lamps in ground glass globes. The lights on the tower are operated by switches grouped within it, and are also in circuit with hundreds more on festoons of smilax carried out to the galleries, like streamers from a huge May pole. The operator in the tower throws all the lights on at once or in sections, and now and then flashes them in time with the music. The effect under any of the conditions is most beautiful, and it is understood that Mr. Stieringer proposes to try some further startling combinations of the novel and the beautiful, all to be achieved with apparatus grouped in the tower. It is a detail, but worthy of note, that all the wires within the the tower, and they are not a few, are run through "interior conduits" which lend themselves aptly to this class of work. The "Tower" has already become one of the great features of the show. A curious part of the matter is that many of the people who stand and admire it do not know that it is a product of American taste and skill but think that it "came from Paris" with the rest of the Edison exhibit and the latest spring fashions. When they learn that it is wholly an American idea, they seem surprised that such is the case, and go away gratified and patriotically pleased with the electric rival to the iron Eiffel.

Judge Wallace of the U. S. Circuit Court has handed down a decision sustaining the demurrer to the complaint in the suit of Thomas A. Edison against Ezra T. Gilliland and John C. Tomlinson. Edison alleged that he authorized Gilliland to sell his phonograph company stock; that Gilliland found a purchaser—Mr. Lippincott, of Philadelphia; that a contract was made for the sale, and that then he made a discovery. It was that Gilliland, having taken Tomlinson in with him, had agreed that Mr. Lippincott should take the stock for $500,000 and should pay $250,000 for certain agency rights to sell phonograps held by Gilliland. Gilliland, Edison charges, represented that he was to be paid for his agency rights in stock not worth over $75,000, and at the same time had an agreement with Lippincott to take the stock off his hands at par. Mr. Edison sued to recover the $250,000, which he alleged the defendants had obtained by fraud. Judge Wallace says: "The bill is fatally defective, because the facts set forth do not disclose that the plaintiff has parted with his stock or otherwise been a loser in consequence of the alleged misconduct of the defendants. He has entered into an agreement to sell and deliver his stock at a future day upon receiving the purchase money, but that day had long expired before the contract was ever consummated. For all that appears he has the stock now, is still its owner, and nothing ever came from the contract. Whether Lippincott repudiated it or whether the plaintiff did or whether it was carried out is left wholly to conjecture. It must be assumed upon demurrer that the plaintiff has stated his case as favorably as the facts will permit. It must be inferred, therefore, that the contract for some unexplained reason has fallen through and that the plaintiff is in the same position as before it was made. The case as stated by the bill is at best one in in which a principal has employed agents to sell property for him and they have taken advantage of their agency to sell their own property at a price largely in excess of its real value. The case is not one where the principal has lost the sale of his own property by the misconduct of his agents, but the theory of the bill is that the property was actually sold, while the facts alleged show that the sale has never been completed, and consequently that the plaintiff has lost nothing by the transaction."

NEW YORK, April 12, 1890.

PHILADELPHIA.

Chief Walker's Report on the Electrical Bureau.—Ferreting out Bogus Telephones.—A Suit Against the Frankford Merchants' Electric Light Company.

THE Chief of the Electrical Bureau made his annual report a few days ago. The report commends itself to consideration, as it enters into the workings of the various systems of electric lighting; telegraph and telephone and conduit companies using the streets of the city for the above purpose.

The careful supervision maintained by the Electrical Bureau of the overhead construction has a resultant effect, inasmuch as no fires and but four deaths have occurred in this city since the introduction of electric light, three of which were employees of the electric light companies and one accidental, caused by a fireman cutting a wire from the roof of a building, which, falling across the electric wires, carried their current to the street, where a boy became entangled in it with the result mentioned. The bureau has tested and has in operation an underground system for the arc light wires and for telegraph and telephone service, which has been found to work in a satisfactory manner.

D. R. Walker, chief of this Bureau, does not hesitate to endorse this system. His experience that it can be made to work in a manner that will greatly improve the service, as well as reduce the cost of maintenance materially, and at the same time remove from our streets the unsightly wires and poles.

During the past few months the American Bell Telephone Co., of Boston, has had detectives at work in this city endeavoring to ascertain how many "bogus" or outlawed telephones were in use here. Over 200 have been discovered, and last Thursday the first batch of fifteen or twenty liverymen, doctors, dentists, druggists and fuel dealers who have been using the infringing telephones were summoned to appear in the United States Circuit Court on the first Monday in May. Dr. S. M. Plush, Manager of the Bell Telephone Co. of Philadelphia, said last evening: "Those bogus telephones are doubtless the remains of the assets of some former competitors of our company. Somebody has been trying, evidently, to work off those old 'phones. Two years or more ago the American Bell Co. brought exactly the same kind of a suit against a number of business men, some of whom are on the list at this time. They were all released upon the promises that they would not continue to use the infringing instruments. Such will not be the case this time. I cannot understand how so many good business men can permit themselves to use what they know it is against the law to use. Every intelligent business man knows of Professor Bell's victory in the courts. I am astonished, so was the American Bell company's agent, at the number of illegitimate telephones that have been in use in Philadelphia during the past year or two. We meet constantly with wires not our own, and we know of course, that they are "pirates."

The Westinghouse Electric Co. recently brought suit against the Frankford Merchants' Electric Light Co., to recover $7,882.01 for a claim arising under a contract entered into between the parties, in pursuance of which the plaintiffs furnished defendants with material and labor used in the construction of an arc electric light plant in defendants' station in this city, consisting of dynamos, lamps, armature, etc., etc., and work of construction.

PHILADELPHIA, April 12, 1890.

CHICAGO.

Mr. Pumpelly before the Chicago Electric Club.—Purchase of the Winsor-Wirtz Lightning Arrester.—The National Engineering Bureau.—The Bucket Shop Fight.

ON Monday evening, the 7th inst., an able and interesting paper entitled "Storage Batteries to the Rescue," was read before the Chicago Electric Club by Mr. J. K. Pumpelly, who pointed out very clearly the occasion when the accumulator comes in as an aid to the dynamo-electric machine, and its many general features of advantage and utility. This paper called forth a lively discussion upon the commercial success of storage batteries, participated in by Messrs. Sperry, Kempt, DeLand, Black, Bauer, Degenhardt and Badt, in which the various merits and demerits of the much maligned secondary battery were pretty thoroughly commented upon.

The Westinghouse Electric Co., of Pittsburgh, have just purchased the Winsor-Wirtz lightning arrester, which it is claimed is simpler and more reliable than any at present in the market.

The National Engineering Bureau is a new enterprise, with offices located in the Rookery. Its promoters, Mr. Thos. G. Grier and Mr. Jas. A. Lounsberry, are gentlemen of known ability and extensive theoretical and practical knowledge in engineering and electrical work. The object of the bureau is to carry on a business in testing, drawing up reports and specifications, and especially carrying out inspection work.

The Board of Trade made another move this week in the fight against the bucket shops which closed up one more avenue through which they might get quotations. Commission firms which have posted quotations on blackboards in their offices for the benefit of their customers were requested by the management of the board to discontinue the practice for the present. They all acquiesced, and the result was that the bucket shops were incommoded to a greater degree than at any time since war was declared against them. They failed to get more than one out of ten of the regular quotations, and these were not posted until about five minutes after the trade was made on the floor of the board. Consequently the bucket-shop proprietors are taking a pessimistic view of the situation, while the Board of Trade people are correspondingly elated. As an instance of the decline of the bucket-shop business in outside towns, it is stated that the proprietors are canceling their orders for the commercial circulars published here, which they have always subscribed for to be distributed to their customers.

They deem it advisable to cut down all their expenses until the result of the fight is known.

CHICAGO, April 12, 1890.

BOSTON.

Resignation of Mr. S. E. Barton and Captain William Brophy.—Their New Sphere of Work.—The Electric Mutual Insurance Co.—Increase of Thomson-Houston Stock.—Edison Toy Dolls Now Ready for Sale.—Supervision of Electric Wires—Speed of Electric Cars.—Cambridge Allows Tow Cars.—Extension of the Edison System.—The West End Street Railway.—The Laminar Fibre.—The Berrenberg Vacuum Pump for Lamps.

MR. S. E. BARTON, chairman of the electric light committee of the New England Insurance Exchange, and Captain William Brophy, chief inspector of the New England Insurance Exchange, have both resigned their positions, and from the first of April have entered upon their new duties, the former as president and the latter as chief inspector of the Electric Mutual Insurance Co., with headquarters at 85 Water street, Boston. Mr. Barton has been connected with the New England Insurance Exchange since its organization in 1883 and Captain Brophy since April, 1886. Both gentlemen have been regular attenders at the electric light conventions, and are most favorably known amongst electric light men from all parts of the country. From an underwriter's point of view, their opinion of an electric light station is extremely valuable and perfect, a very short examination, the result of extensive experience, being necessary by them to determine the true character of a plant as regards fire risks. The schedule for rating electric light central stations about a year ago is too well known to require discussion, and it is interesting to note that since that schedule was adopted by the New England Insurance Exchange, in April, 1889, a very similar schedule has been adopted and partially applied by nearly all the other insurance organizations, among them being the New York State organization, the Middle States', Philadelphia, the Southern States', at New Orleans, and the Southeastern Tariff Association, at Atlanta, Ga. Messrs. Barton and Brophy's past experience has thus eminently fitted them for the sphere of work upon which they are now entering, and success is sure to crown their efforts in providing for all electric light and power companies an insurance company which will fully understand their requirements, issues policies suitable to the case and prevents them from insuring in half a dozen more companies, each one of which has conflicting suggestions to make before it will issue a policy.

The Electric Mutual Insurance Co. proposes to commence to issue policies on May 1st.

They have prepared and are about to send to all electric generating stations, a small pamphlet (the full text of which is printed on another page), setting forth the requirements for construction, equipment and maintenance of standard electric light or power stations. Already over $2,000,000 pledges have been given, that is, insurance ready to place on May 1st. The Electric Mutuals, as it is commonly called, will begin by issuing not more than $15,000 insurance on one station, but will place the balance at the same rates with eight or ten of the strongest English and American insurance companies, who have placed their agencies with the Electric Mutuals, and will accept lines varying from $5,000 to $10,000 on any station accepted by the Mutual company. All the examinations of the stations will be left entirely in the hands of the Mutual company, Captain Brophy and such assistants as he may require, performing functions with regularity and intelligence, and no cancellation of policy will be possible. Besides issuing policies on the stations, the Mutual company will also insure street circuits and lamps under separate policies, a class of insurance which has hitherto been extremely difficult to obtain from stock companies, first, because they are afraid of the supposed dangers of the current, and secondly, because they are already loaded with insurance on the buildings and their contents in every city, and have all that the insurance laws will permit them to carry. To accommodate stations at a distance, blank surveys will be sent at present, though probably inspectors will be appointed in a number of local centres as the business grows. Messrs. Barton & Brophy have the good wishes of a host of friends, who desire for them every success in their new enterprise, believing that they are acting for the distinct benefit of every holder of electric light stocks and securities in the country.

The stockholders of the Thomson-Houston Electric Co., at a special meeting held at Middletown, Conn., voted to increase the capital stock $3,000,000 making the total capital stock outstanding $11,500,000.

The Edison Toy Doll Co., have at last got their dolls perfected for the market, and have begun to deliver them in fulfillment of orders. They are now making them at the rate of 300 to 400 per day.

The mercantile committee had a hearing this week at the State house, upon several orders relative to the supervision of electric wires. E. W. Burdett appeared for the Massachusetts Electric Lighting Association, G. A. Bruce and S. L. Powers for the American Bell and New England Telephone Companies, and F. A. Wyman for the Westinghouse Electric Co. Mr. Means argued that the wires as they existed to-day were not properly guarded, and claimed that compulsory legislation was necessary for Boston, to compel companies to remove their dead wires, as the city council cannot pass such ordinances. Mr. Powers argued strongly in favor of allowing things to remain where they are, and claimed that it would be a poor policy to establish a state commission for the regulation of the wires, New York being an example of such a policy. He claimed that the electric companies were amply able to look after their own wires, and that there was no need for legislation. The hearing has been continued.

As was to be expected the slow speed of the electric cars has so annoyed the traveling public that, at a recent meeting of the board of aldermen two petitions from prominent business men of Boston, were presented asking that the standing regulations of the board of aldermen be so amended as to allow street cars to run at a rate not exceeding 12 miles an hour on Shawmut avenue, south of its junction with Tremont street. To illustrate how easily it is for complaints to be made on alleged over speed, it is amusing to read the following story copied from a daily journal: "A driver of one of our slow-going electric cars tells an experience with an old gentleman who rode in from Cambridge one day, and, becoming alarmed at the 'great speed' of the car, threatened to report the matter to the superintendent. He did so, and the driver was called up for a reprimand. 'This man complains that you ran your car at least 15 miles an hour,' said Superintendent Monks. 'What have you to say to the charge?' 'Well,' answered the driver, 'if I ran my car 15 miles an hour you must have pretty swift horses on your horse cars, for I followed one all the way from Central Square.' He went back to his car minus the reprimand."

At a recent meeting of the Cambridge board of aldermen the recent order for the withdrawal of tow cars was rescinded and the board gave the West End Co. permission to run the cars, providing that two men be placed in charge of each car, that the company reopen its South Boston line for one fare, and that fenders be placed on the cars at the earliest date possible.

THE Edison Electric Illuminating Co. has declared a quarterly dividend of one per cent., payable May 1. During the coming spring and summer they will make extensive alterations on their premises at Head place, and have commenced operations to increase their present building two stories. The present office room will be used for an extension of the dynamo room, and the office, stock rooms and meter room will be moved upstairs. Extensive increases in the underground operations are now in progress, and the Back Bay Incandescent Co., which was organized some months ago for the purpose of providing lights for the Back Bay district, has made arrangements with the Edison company to run feeders and mains there this summer, and will be heard of no more. Mr. C. L. Edgar, the general manager of the Edison Illuminating Co., returned from his European trip last week, and all the alterations will be made under his careful supervision.

At a meeting of the Society of Arts, held in the new Institute of Technology building, Professor Elihu Thomson read a very interesting paper on "Experiments with Alternating Currents," practically illustrated. It covered the ground given in THE ELECTRICAL ENGINEER'S abstract this week.

Before the Street Railway Committee, ex-Governor Long made the closing argument in favor of allowing the West End Street Railway Co. the privilege of erecting an elevated road in the more crowded parts of the city. He argued that there was a necessity for increased facilities and more rapid transit, a fact which, he said, showed beyond all doubt that the company's petition was entered in good faith. He declared that the necessity could be best met by the West End company, with the minimum of inconvenience of cost and of danger, and with the maximum of convenience, of safety and economy. The electric car will still hold the surface of the streets, whatever charters are given, and all the West End company asked for was the privilege of relieving the streets in the crowded part of the city. Following Mr. Long, came Mr. Solon Bancroft, of Reading, who made the closing argument for the People's Elevated Railway Co. (C. H. Nichols and others). He contended that it would be for the benefit of the people that there should be an independent system of elevated roads, having no connection with any existing organizations, and he claimed that there was no danger of combination with the West End or other corporation. G. H. Towle, of Boston, closed for the Meigs petitioners. He severely criticised the West End bill, and said there was no rapid transit in it. It was only a transfer to the West End company of all rights and powers of the general court over the streets of Boston and the surrounding towns. Arguments will follow for White, Bartholomew, Mac and Torrey in the order named, and the outcome is looked forward to with an immense amount of interest.

The West End Street Railway Co. have petioned the Cambridge Board of Aldermen for permission to set up and maintain boilers and engines at the old glass house in East Cambridge, which it had recently purchased for a power house, and permission to run feed wires from that building to the company's electric lines. Foundations of the new power house in Cambridge have been laid and the brick work started. The equipment of this plant will consist of 10 250-h. p. dynamos, which will furnish power to about 250 electric cars. Until the station is completed this fall, the power will be furnished by the Cambridge Electric Co.

The Laminar Fibre Goods Co. has been organized, with headquarters in the New England building, for the purpose of manufacturing an insulating material called "Laminar Fibre," which is made either in sheets or tubing, hard or flexible. Mr. C. H. Whall, the manager of the company, has been connected with the manufacture of fibre goods for several years, and Mr. T. S. Hanna, the superintendent of the factory, which is situated at North Cambridge, is the original promoter of fibre interests in this country, having been connected with its manufacture for about 14 years. Laminar fibre in sheets and in its natural color, looks and cuts like a piece of horn, and is perfectly homogeneous in its nature, and can be used for an infinite number of mechanical purposes, such as bearings for light running machinery, small pulleys, toothed noiseless gearing pump valves, etc. It will stand an immense amount of heat, and is non-inflammable, possessing also great tensile strength and resistance to compression. Though it can be made of any color for insulating purposes, Mr. Whall recommends the natural gray color, which prevents the introduction of any foreign or mineral substance to produce the coloring. It can be tapped and screwed, and machined into any shape, and there is practically no limit to the field of its uses. For pulleys it requires no bushing, laminar itself being able to outwear any steel spindle ever made. The factory is one of the finest in the country for the production of fibre goods, costing $60,000, and is fitted with the best and most modern machinery for the manufacture of laminar into any desired shape.

Several very interesting exhibitions of the Berrenberg vacuum pump, the invention of Mr. Adolph Berrenberg, of Somerville, have been given this week at 109 Purchase street. The pump is designed for exhausting incandescent lamps, instead of the present mercurial pumps now used by all lamp manufacturers. The pump is not entirely new, experiments having been made with it some years ago, but it is only within the past few months that it has attained its perfection in the hands of Mr. Berrenberg, assisted by Mr. Wm. E. Nickerson, a mechanical and chemical expert. This week, Mr. J. E. Randall, superintendent of the Thomson-Houston lamp factory, and Mr. J. R. Lovejoy, were present at some tests, and have exhausted a few lamps of their own manufacture for the purpose of future experiments. The pump, to look at, is an ordinary three-cylinder piston air pump, but the inside construction of it has not yet been made public. Lamps can be exhausted in 15 minutes by the Berrenberg pump, against five hours by any mercurial pump, and show by the mercurial tests wonderful results. The current can be put on the lamps in 30 seconds after the pump starts operation. The degree of exhaustion is very easily tested by breaking the stem of a lamp after it is sealed, under mercury, when the mercury immediately rushes into the lamp to supply the vacuum. The air left in the lamp is shown by a small globule, and the smaller the globule the better the exhaustion. It is not too much to say that the globules of air in lamps exhausted by the Berrenberg pump were as small, and in many cases smaller, than those in lamps exhausted by the small mercury pump. Tests are also being made on the life of the lamps, which are up to the present entirely satisfactory, some being shown which have burned about 600 hours, considerably over potential. The result of the investigation by the various lamp companies will be looked forward to with great interest, as the use of this machine, ought to cheapen the manufacture very considerably, since the process of exhaustion forms from 20 to 30 per cent. of the cost of manufacture. The claims made for the pump, and which appear to be well borne out by the experiments, may be briefly summed up as follows: It does in minutes what now takes hours for a mercurial pump, and the work is better and more uniform; it does also what would require hundreds of mercurial pumps; it takes up very little room, and will not poison those who work it; the lamps made by it are better than others, and will burn longer on account of the uniformly good vacuum it produces. The pump has a strong syndicate interested in its development and it will soon be put to practical use.

BOSTON, April 12, 1890.

PITTSBURGH.

Developments in Electric Railroading.—Telephonic and Railway Interference.—Damage by the late Gale.—Electricity as a Manufactured Article.

THE Duquesne Traction Co.,—the corporation, which is going to cover this whole city with a network of electric street car lines,—evidently does not intend to let grass grow under its feet. Last week work was already begun on the power-house, which is to be built on the corner of Fifth avenue and Craig street. The company proposes to have the first car running by next fall. Car loads of Belgian block are constantly arriving and everything is pushed along as rapidly as possible. The directors of the company have, however, not yet decided which system of electric motive power is to be utilized.

The Troy-Hill electric railroad company has received a charter from the Governor of Pennsylvania for the purpose of building a street car line from Allegheny city to Troy Hill. The company has a capital stock of $100,000. The line will be about three miles long and it is almost decided by the company to operate the line with the Sprague electric motor system.

Charters were also granted to the following corporations of this city: The Exchange street railway company, four hundred feet in length, capital $1,000. The Monongahela street railway company, one mile in length, capital $3,000. The Grant street railway company, one half mile long, capital $6,000. The Riverside street railway company, three-tenths of a mile in length, capital $1,800. All of these lines are intended for feeders of the Duquesne Traction Co.

The local telephone and telegraph companies are constantly expressing their undisguised displeasure at the rapid development of the electric street car systems in this city, They make the charge that the many street car wires interfere greatly with their own wires. The telephone company has been compelled to move its wires entirely off Second avenue, where an electric road is operated with the Thomson-Houston system.

The high wind, which swept like a cyclone over the eastern portion of Ohio last week made itself also felt in this city very strongly and considerable damage was done here to the electric wires. The Second avenue electric line had to cease operation for several hours, on account of one of the wires breaking on Fourth avenue.

The plan, to build an electric railway from Allegheny city to Belleview, which was started some time ago, has been abandoned, on account of the inability of the promoters to get the necessary funds for the enterprise together. A bridge would have had to be erected across Jack's Run to complete the line, and the cost of this structure seems to have frightened the promoters of the enterprise.

The Citizens, Traction Co., which is now operating a cable road from Pittsburgh to Lawrenceville, has decided to build an electric line from the present terminus to Sharpsburg a distance of two miles. The latter is now operated by horse cars.

Judges Simonton and McPherson, of Harrisburg, Pa,, recently listened to the argument of two cases for the purpose of determining whether electricity or electric light is a manufactured article. The Brush Electric Light Co., and the Philadelphia Electric Lighting Co., refused to pay the tax levied against them because they are manufacturing companies. The commonwealth, however, seems to have a different idea of the case, and has therefore asked the courts to decide the matter.

PITTSBURGH, April 11, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

THE PUFFER TESTS OF INCANDESCENT LAMPS.

[122.]—On page 162 of your issue for April 2, there are five tables showing the efficiencies of the lamps of various makers.

These tables are the authorized production of the Rogers' Laboratory of Physics, Massachusetts Institute of Technology, of Boston, bearing the endorsement of Professor Wm. L. Puffer.

These tables show that various lamps of well-known makers vary in efficiency expressed in terms of watts per horizontal candle power from 2.45 to 4.26 watts per candle. These tables on examination will be found worthless when it is noticed that lamps are not burned at the candle power they were made for, and at which they are ordinarily used in commercial practice.

There may have been no partisan spirit running under the tests, but the casual reader would be led to infer that the tables expressed the relative value of the lamps tested. Whereas the tables only express that lamps wrongly marked were tested at the false volts marked on them rather than at the candle power the lamps were made to burn at.

If it were not for the weight of the names attached to the paper I should consider it only a subject for passing ridicule. But bearing the stamp which should only seal valuable *and complete* work, and giving as it does wrong impressions, the paper should not pass without protest. FRANCIS R. UPTON.

HARRISON, N. J.

SOCIETY AND CLUB NEWS.

BUFFALO ELECTRICAL SOCIETY.

Madison Buell read a paper on "Rapid Transit" before the Electrical Society on April 7.

It was admitted by electrical and other people, the speaker said, that this country had made greater progress in the application of electricity to railways than all the rest of the world. On January 1, 1890, there were 151 roads in operation and under contract, with an aggregate of 1,641 miles and 2,346 cars. The street railway company of Minneapolis threw aside the half million unused cable plant, adopted the electrical system of transit, and has made a big success of it. Yet Buffalo was now going through the chrysalis stages of discussion and arguments relative to the adoption of such a system.

The same arguments, the same objections, had been gone over in nearly 200 towns and cities, and they had been met and answered decisively. The Buffalo Street Railway Co. refused to adopt, and wisely, too, the cable system, but was willing to adopt the trolley system, subject to certain conditions acceptable to the people of Niagara street. There were grave and even insuperable objections to the storage battery.

In THE ELECTRICAL ENGINEER of April 2, he said, was an illustration of the new Sprague railway underground work, and this was undoubtedly the system that the Buffalo Street Railroad Co. intended to put—or ought to put—on Niagara street. This plan, as described, contemplates carrying double trolley wires between double tracks, with the mains and feeders carried in insulated feeders underground. The sub-feeder wires between the main line and the trolley line will be carried up the interior of the poles in insulated "interior conduited" pipes. Another set of wires for lights will be supplied from a separate switching circuit running direct from the station and connected with all the series of light on the poles. The details of this system, it was claimed, give a very excellent form of construction for street railways, making the overhead system entirely unobjectionable and furnishing also the lights for the streets through which the road passes, the control of the lights being from the power station direct.

Holding it to be proved that the pressure of electricity used for the trolley system is not dangerous to life, the lecturer held that the danger to be feared was simply from the network of wires used in its present construction, and their proximity to the electric light wires. The Senate Committee on General Laws having presented to the Senate a report which recommends that all electric light wires be placed under ground, the danger constantly menacing the trolley system would be abated.

The railway people should have authority to move their tracks one foot toward the curbing of the sidewalks. This would be an item of expense which would be vigorously opposed by them, but it would have the effect of giving the citizens a new road the entire route, besides giving a wider space between the two tracks, which would not interfere with the regular traffic of the street. This extra space would be required anyway for safety, as the electrical cars run much faster than the horse cars. The courts and the legislature having taken hold of electrical matters and obviated the greater part of the dangers of electric railway traffic, it was only necessary for the Niagara street people to come to some understanding with the street railway officials and arrange the details of a system that will prove beneficial and satisfactory to both parties and a source of pride to the citizens of Buffalo.

NEW YORK ELECTRIC CLUB.

The Electric Club will hold its annual meeting for the election of officers at its club house, 17 East Twenty-second street, next Thursday evening, April 15.

.. NO PART of the writings of Franklin exhibits his sagacity and his power of sicentific generalization in a more conspicuous light than his theory of electricity. The talent to discover isolated facts in any branch of science, although possessed by a few, is comparatively inferior to that characteristic of mind which leads to the invention of an hypothesis embracing in a few simple propositions whole classes of complete phenomena.—*Joseph Henry.*

BRIGHTER PROSPECTS FOR THE U. S. PATENT OFFICE.

A SPECIAL dispatch from Washington of April 11 says: "It is a topic of common remark that the golden age of invention is at hand, if encouragement by the government counts for anything. The present Congress seems more than merely well disposed towards the patentee class. Representative Butterworth's bill appropriating three million dollars to build a new Patent Office has been favorably reported to the House, and will probably go through as even the strictest economists will not complain that the sum is exorbitant in view of the character of the building required, nor can it be argued that it is a bad business idea to give a proper housing to the one bureau of the government which brings in a handsome yearly revenue above all expenses. The money to be spent on the new home for the Patent Office bears no extravagant proportion of the amount which actually stands upon the books of the treasury to the credit of that institution.

Mr. Simonds' bill, also increasing the pay of the leading members of the Patent Office force, is regarded as having a fair prospect of success. With the host of other channels of expenditure clamoring to be filled by the present Congress, there may be some reduction of the amount to be distributed in increased salaries for the present; but Commissioner Mitchell cogently remarks: "The primary examiners are now drawing no more pay than they were in 1848, when the labors of everybody in the office were infinitely lighter, and when the competition for first-rate ability between the government and the business world outside was not nearly so sharp. It cost less to live, and the best men could afford to work for lower pay. But it is all wrong to continue nowadays the salary-list of that period. The inventors themselves have a right to demand better treatment at the hands of the government. If they are willing to pay good fees, it is only reasonable in them to expect the best service their money will buy. What is the fact? We are taking from them hundreds of thousands of dollars of their money every year; we shall turn into the treasury this year a cool $228,000 over and above all the expenses of running the office. The increased salaries proposed by Mr. Simonds would foot up about $60,000, leaving $168,000 clear profit still. Is it an extravagance to ask such an advance from Congress?"

Another consideration which will incline many person to look kindly upon Mr. Mitchell's recommendations is the fact that he has shown, thus far, a proper respect for the dignity of his own office, and for the technical character and standing of the bureau over which he presides. Though a Republican partisan of the strictest stripe, he appears to have conducted his bureau generally in accord with the spirit of civil service reform. That is a good deal to say for a bureau chief who is responsible to such a cabinet officer as secretary Noble. The result of Mr. Mitchell's business-like administration is that the work of the office is nearer abreast of the incoming business than it has been for several years, and patents are turned out faster than ever before, without any apparent neglect of the preliminary details.

THE NATIONAL FAST TELEGRAPHING TOURNAMENT.

IN accordance with the arrangements made by Mr. Fred Catlin, its promoter, the National Fast Sending Telegraphic Tournament, came off on Thursday afternoon and evening, April 10, at Hardman Hall, this city, when money prizes aggregating $820 were competed for by the largest gathering of contestants ever seen on such an occasion, and in the presence of hundreds of spectators. The contestants were divided into four classes as follows:—

Ladies' Class.—Free for all. First prize, $50; second prize, $40; third prize, $20.

Class A.—Open for all. First prize, $100; second prize, $70; third prize, $30.

Class B.—Open for all, barring those who made a record of better than 11 minutes in the contest of 1885. First prize, $85; second prize, $65; third prize, $30.

Old Timer's Class.—For those who were in the service prior to 1865. First prize, $50; second prize, $40.

Mr. A. B. Chandler offered a prize of $10 for best pen and ink copy, and $10 for clearest transmission, regardless of speed, to each of which the management added $10. The United Press offered $25, to the contestant, in each class, adjudged to have done the most finished and accurate sending in the quickest time. During the evening a telegram from J. I. Sabin, of San Francisco, received through the *Electrical Review*, added $100 to the prize fund, and a Commercial Cable dispatch from Dunfermline, Scotland to Mr. T. C. Martin, of THE ELECTRICAL ENGINEER, announced that the Hon. James D. Reid, now U. S. Consul at that port, would present a handsome Cairngorm brooch to the prize winner among the ladies. The other prizes were offered by the Western Union and Postal Telegraph-Cable Co.'s, Andrew Carnegie, Genl. Thomas T. Eckert, Thomas A. Edison, A. B. Chandler. W. P.

Phillips, The Associated Press, The United Press, the *Electrical World*, *Electrical Review*, the *Electric Age*, the *New York World*, The E. S. Greeley & Co., J. H. Bunnell & Co., Western Electric Co., the New Haven Clock Co. and E. H. Johnson.

The officers were as follows :—

JUDGES.—Walter P. Phillips, Gen'l Manager of the United Press; Thos. R. Taltavall, Editor of the *Electric Age;* Geo. H. Usher, Manager Postal Telegraph-Cable Co.; E. F. Howell, Official Tester Western Union, central office; Geo. E. Holbrook, of the *N. Y. World*. STARTER.—C. W. Price, of the *Electrical Review*. TIMER.—W. J. Johnston, of the *Electrical World*. MASTER OF CEREMONIES.—R. J. Hutchinson, Superintendent Telegraph, Stock Exchange.

In addition to the record taken by the judges, Mr. P. B. Delany volunteered to keep score with his ingenious new speed indicator, on which he is securing a patent. This instrument, placed in the local circuit, with the sounder, will indicate with absolute correctness up to a speed of 100 words per minute. One hundred thousand words may be indicated without rewinding. Thus the number of words transmitted over a wire during a day, or the amount of actual work done by an operator, may be ascertained with perfect accuracy. In competitive trials of speed the indicator will detect the omission or addition of a single dot in a trial of any length.

The second hand requires 120 impulses for a revolution, the minute hand requires 60 times that number or 7,200, while the hour hand marks 86,400 impulses for a revolution, which, computed at the rate of three impulses to a letter, and five letters to a word, makes 5,760 words.

Below are given the winning 5-minute records :

Ladies' class.	Delany ticks.	Words and characters.
1. K. B. Stephenson (W. U.)	2,436	217
2. B. M. Dennis (W. U.)	2,426	212—4
3. E. R. Vanselow (W. U.)	2,467	210—4

Special prize of $25 for best sending :

4. T. V. Freschel (W. U.)	2,397	200—5

Old Timers' class.	Delany ticks.	Words and characters.
1. A. S. Ayres, (Postal)	2,576	229—1
2. F. Catlin (W. U.)	1,986	217

Mr. Ayres also took a special prize of $25 for best sending.

There were a large number of entries in class A, but it is unnecessary to give the records of others than the leaders. The record of Pollock, who came from the Hartford office of the New York, New Haven & Hartford Railroad, far surpassed anything ever before made.

Class A.	Delany ticks.	Words and characters.
1. B. R. Pollock (N. Y., N. H. & H.)	2,785; 2,796	258; 260
2. J. W. Roloson (Postal)	2,616	248—3
3. F. L. Catlin (P. W.)	2,718	241—1
4. W. M. Gibson (U. P.)	2,730	239
5. F. J. Kihm (U. P.)		238

This showing left the judges in doubt as to the relative merit of the men for first place, and there was a second and third repetition of the test, with the result that Pollock made the amazing record of 260 words, or two more than on the first trial. The other competitors fell off a little. The first prize in this class was thereupon awarded to him ; the second to Gibson, the third to F. J. Kihm. The prize for best sending was taken by W. L. Waugh (U. P.) with 229 words, sent in 2,221 ticks.

The contestants in class B were quite numerous, and after a spirited struggle the prizes were awarded as follows :

Class B.	No. of words and characters.
1. F. L. Catlin (P. W.)	251—1
2. W. L. Waugh (U. P.)	229
3. F. English (P. W.)	225

Special prize for best sending :

4. J. P. Bradt (U. P.)	220—2

A special prize of $30 for the best sending, regardless of speed, was awarded to A. S. Ayres.

For the receiver's prize only one contestant, T. R. Taltavall of the *Electric Age*, appeared. He took Mr. Waugh's 229 words, and the judges pronounced his copy the finest high-speed writing they had ever seen.

Mr. W. B. Upperman, of the Associated Press, received the transmissions through the day and recorded them on a caligraph.

....NOTHING is so fatal to success in electrical work as apparatus erected in a manner that will just *do*. If a fault occurs, put it right at once and put it right thoroughly, not merely patching it up, thinking to put it right at some future time.—*F. C. Allsop.*

LEGAL NOTES.

DECISION OF COMMISSIONER OF PATENTS.

FORBES *vs.* THOMSON.

A decision was rendered March 26, by Commissioner Mitchell in the interference case of Forbes *vs.* Thomson. A patent was granted August 7, 1888, to Professor George Forbes, of London, for a method of measuring electricity which consisted in passing the current through a conductor traversing a closed vessel, evaporating a liquid therein by the heat generated in the conductor, and finally using the amount of evaporation or quantity of liquid condensed from vapor as a measure. On the same date Professor Forbes filed an application for a patent for an apparatus for carrying this process into effect. Professor Elihu Thomson had filed as early as October 19, 1887, an application claiming a similar apparatus, and interference proceedings were accordingly instituted which resulted in an award of priority to Thomson. As Thomson made no claim to the method, Forbes' patent claiming the method was allowed to issue as stated. After the issue of Forbes' patent, but before the issue of Thomson's, the latter filed a second application claiming the process. A second interference was instituted, but after the preliminary statements had been filed, counsel for Forbes moved to dissolve the interference, claiming that Thomson's application for the process was not properly a division of the the original application. The primary examiner granted the motion to dissolve, whereupon Thomson appealed to the commissioner. The commissioner now overrules the decision and reinstates the interference.

EDISON *vs.* THE UNITED STATES ELECTRIC LIGHTING CO.

On March 28, two motions were made by defendants before Judge Lacombe, in the case of The Edison Electric Light Co., *vs.* the United States Electric Lighting Co., in equity No. 3445, in which the Edison filament patent No. 223,898 is in litigation. The first motion was for leave to defendants to amend their answer and to set up as a defense the expiration of the Edison patent by reason of the lapsing of a later Swedish patent which the defendant claimed operated to terminate the prior Canadian patent and through that invalidated the United States patent. It was contended by the plaintiffs that the point was entirely covered by the recent decision of the Supreme Court in the case of Pohl *vs.* Anchor Brewing Co., but Judge Lacombe granted the motion in order that the facts might be in the records when the case came before the Supreme Court.

The second motion by defendants was for an order to compel the plaintiffs to furnish them with certain papers in a pending application of Mr. Edison filed in the fall of 1880, in which the defendants assert would be found statements limiting the scope of the Edison filament patent. These statements, it is claimed by the plaintiffs, have been made by persons formerly employed in the Patent Office and therefore surreptitiously obtained. Judge Lacombe denied the motion.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued April 8, 1890.

Alarms and Signals :—*Electric Alarm Devics for Clocks*, F. H. D. Schwarz, 425,004, *Electrical Annunciator Drop*, M. Hynes, 425,078. *Thermostat*, W. P. Singer, 425,089. *Thermostatic Coil*, D. W. Thompson, 425,114. *Burglar Alarm*, J. Moran, 425,143.

Conductors, Insulators and Conduits :—*Machine for Weaving Insulating Covering on Electrical Conductors*, C. T. Stetson, 425,036. *Pole for Electric Wires*, L. R. Greene, 425,071. *Device for Shielding and Protecting Wires*, H. E. Penney, 425,107.

Dynamos and Motors :—*Electric Rotary Pump*, E. I. Nichols, 425,106.

Galvanic Batteries :—*Electrode for Galvanic Batteries*, W. P. Kookogey, 425,135. *Process of Manufacturing Metallic Electrodes for Batteries*, F. Marx, 425,335.

Lamps and Appurtenances :—*Electric Lighting and Advertising System*. A. Douglass, 425,125.

Measurement :—*Voltmeter*, M. M. Garver, 425,068. *Ammeter*, M. M. Garver, 425,069. *Electric Meter*, M. E. Thompson, 425,269 and 425,270.

Metal Working :—*Method of Electric Welding*, C. L. Coffin, 425,164.

Miscellaneous :—*Switch-Board*, E. A. Owen, 424,995. *Electric Stop-Motion for Warping Machines*, J. E. Prest, 424,997. *System of Telpherage*, J. E. Maynadier, 425,038. *Lightning Arrester*, J. D. Bishop, 425,061.

Railways and Appliances :—*Electrically Propelled Vehicle*, R. M. Hunter, 425,076. *Electric Railway Car*, R. M. Hunter, 425,077. *Support for Electric Railway Conductors*, C. J. Kilian, 425,101. *Electric Railway Apparatus*, J. B. Odell, 425,388.

Telegraphs :—*Central Office System for Autographic Telegraphs*, J. H. Robertson, 425,086.

Telephones and Appliances :—*Graphophoning*, D. W. Brown, 424,956. *Telephone Toll-Box and Connection Register*, C. E. McCluer, 424,993. *Telephone Toll-Box*, H. L. Cassard, 425,161.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

A MAGNETIC PEN-HOLDER.

Various electrical devices have been invented for the prevention of what is known as writer's cramp, but if we are to credit the contents of a patent recently issued to Mr. Edwin A. Hill, the application of magnetism alone is sufficient to effect a cure. The inventors claim to have found that "by the use of a magnetic pen-holder, owing to the action of the magnetic currents from the poles of the magnet or magnets forming the pen-holder on the muscles of the hand which holds it, the user cannot experience writer's cramp to any appreciable extent."

THE FRINK SYSTEM OF REFLECTORS.

THE arrangement of the electric lights that the executive committee of the Metropolitan Museum of Art, New York, has determined to place throughout the entire building has caused the committeemen a great deal of bother and worry. There were different opinions as to the best arrangement of lights for the galleries of paintings The question was settled by having the electricians arrange lights according to different methods in different rooms for inspection. At the meeting of the full committee, I. P. Frink's system of reflectors was unanimously adopted. With these reflectors the paintings will be evenly covered with a light without glare, and throwing the interior of the room into the shade. Now that this is decided upon the work of lighting every gallery in the museum is being rapidly pushed by Mr. Frink, and very soon the museum will be thrown open on Tuesday and Friday nights for the accommodation of the public.

NEW WESTINGHOUSE WORK.

The Westinghouse Electric Co. has been awarded the contract for installing a new central station plant for electric lighting in Portland, Va., with alternating current apparatus. The plant will be started with a capacity of 1,500 lights.

The Monongahela Mining Co. is about to light one of its mines by electricity. The plant is to be of a special character so as to make it perfectly safe and economical. A current pressure of 300 volts will be utilized on the line and the lamps will be placed in series of three throughout the mine. The capacity of the plant is 150 lights and The Westinghouse Electric Co. has the contract for furnishing the apparatus.

The new Westinghouse arc lighting system is to aid in dispelling the nightly darkness at Troy, N. Y., in the near future. The Westinghouse Electric Co. has received an order from that place for a 60-light machine.

Salt Lake City is to have a lighting plant to use the Westinghouse alternating current incandescent system. The initial capacity of the plant will be 500 lights only, but the prospects are good for an increase at an early date after getting the apparatus at work.

APPROVAL OF THE INTERIOR CONDUIT SYSTEM.

It will be remembered that in THE ELECTRICAL ENGINEER of April 2, was published an illustration of the underground system developed by the Interior Conduit and Insulation Co., of 16 and 18 Broad Street, this city. That system has now been adopted for Detroit and will be put in there by the the Detroit Electric Light and Power Co., to carry services of all classes and potentials.

With regard to the "interior" system proper, the company has received from Mr. Frank Kitton, insurance inspector of the city of Buffalo and chief operator of the Western Union Co. there, the following letter:—

"Replying to your favor of March 29, 1890, asking my opinion of the utility of your system of electric wiring, I am glad to be able to say I regard it as one of the greatest advances made in this direction, since electric lighting became a commercial possibility.

"The use of your conduit tube provides great immunity from the dangers that may arise through the development of excessive heat in conductors of electricity, protects the wires from mechanical injury and excludes moisture.

"The system is so flexible, and possesses such engineering advantages as to commend its adoption to those seeking a systematic method of providing for the wiring of buildings in the course of construction, as well as others, more especially concerned in the safety of electric light and power installations."

This is, however, but one of the testimonials held by the company from prominent men in the insurance and electric lighting fields.

THE STATE OF THE COPPER MARKET.

"The strength of copper stocks," says the *News Bureau* "is based on the improvement in the metal. Mr. Lewisohn, now in Boston, says that all the leading mines are sold ahead, some up to July 1. The smaller mines have no surplus, and find no difficulty in selling their daily production. Within the past nine months the bankers holding the foreign surplus, the legacy of the old French syndicate, have marketed 15,000,000 pounds of Lake ingot, besides over 1,000,000 pounds of Arizona. Recently the bankers have sold 6,000,000 pounds ingot from 14 to 14½, with the last sale at ¼c. This has all gone into consumption, together with the production of the mines. But for this surplus copper would have sold very high. The holding of the bankers is now estimated at about 12,000,000 pounds, and they could get 14 cents for all of it to-day. The great copper demand is for wire bars and cakes, and of these brands the bankers have none. The Calumet is working day and night smelting wire bars, and the same is true of some of the Bigelow group. Wire bars and cakes are strong at 14½c. If the demand for brass and electrical purposes continues as it has the past nine months all the surplus stock will be wiped out. The consumption to-day is greater than the production. Mr. Lewisohn says, however, that he would be glad to see copper stay where it is, as the more stable the prices the better for the copper interests."

CHANGES IN THE CANADIAN TARIFF.

By changes just made in the Canadian tariff, taking effect at once, the duties are advanced on a number of electrical goods and supplies. Brass and copper wire, bare, will now be taxed 15 per cent.; they were formerly on the free list. Wire covered with cotton, linen, silk or other material, 35 per cent. ad valorem; it was formerly 25. Telephones and telegraph instruments, telegraph, telephone and electric light cables, electric and galvanic batteries, electric motors and apparatus for electric lights, including incandescent light globes, and insulators of all kinds, not elsewhere specified, 35 per cent. ad valorem; the rate was formerly 25.

It is expected that this change will stimulate electrical manufacturing in the Dominion.

"KERITE" WIRES AND CABLES.

Mr. Geo. B. Prescott, Jr., who is so well-known throughout the country as an electrical engineer of high attainments and wide experience, has been appointed general agent for Day's "Kerite" wires and cables, and will carry on the business at the old headquarters, 16 Dey street. Mr. Brixey will continue in charge of the large factory at Seymour, Conn. It is needless to say that in such hands these specialties will lose none of their excellence or popularity. Mr. Prescott assumes his new duties on the 15th, with the hearty good wishes of a very large circle of personal and professional friends.

A NEW SPRAGUE ROAD IN THE SOUTH.

We understand that a northern syndicate has secured control of the electric interests in the towns of Winston and Salem in North Carolina, and that an electric line, connecting the two towns will soon be installed. The line will be five miles long, and will include six cars. The Sprague system of overhead wiring will be used. The dynamos will be located in the electric light station which will hereafter supply both light and power for the street cars and for general industries along the line. This is probably the first station in the country, from which will be distributed electric power for street railway, and general industries, and light by both arc lamps and incandescent. Among the incorporators of the company mentioned, are E. H. Johnson, J. H. Mc Clement, F. J. Sprague and E. B. Hawkes.

Although electric roads are now in operation pretty generally throughout the northern and western states, the use of electricity as a method of propelling cars, has not as yet met with such wide adoption among the cities of the southern states, though it had there its first important introduction.

There are, it is true, a number of cities in the south where there are electric roads in operation, or in process of construction, but the horse and mule are still relied upon in most cities for the operation of the street cars. Northern capital, however, is rapidly developing many of the southern towns, and a few years changes a locality from a condition of inertness to one of business and enterprise.

Salem-Winston is a good example of the progressive towns of the new south, and shows by its interest in electrical enterprises, that it is fully awake to the latest of modern improvements.

THE NATIONAL ELECTRICAL MANUFACTURING COMPANY.

A company as above named succeeds to the business of the electrical department of the New Haven Clock Co., of 29 Murray street, and on May 1 it will remove to 14 and 16 Vesey street. This new departure is one of unusual importance. The new company, which has incorporated under the laws of New Jersey, has among those interested in it several of the most prominent and influential men in New York city. The management of the business will remain as before in the efficient hands of Mr. Noyes. The company takes over from the New Haven Clock Co. all the machinery and tools, patents, etc. that have been used by it, and will add a variety of labor saving machinery, besides being at liberty to employ at any time any of the clock making plant that may be temporarily or specially desirable.

It is the intention of the new company to make all grades of insulated wire, and they state that their facilities in this department will be equal to those of any other wire concern in the field. They will be in full operation by May 15, and will be ready to fill orders of the largest size.

It is a happy augury that at the moment of making this change, the company should have seen their New Haven Clock Co.'s telegraph key used by the winner, Mr. Pollock, last week, in the National Fast Telegraphing Tournament. This key was used by several of the speediest contestants, and with it Mr. Pollock made the phenomenal record of 260 words in 5 minutes. A peculiarity of the key is that it has no steel lever; and it is claimed that it is very superior in maintaining its elasticity.

THE BUCKEYE ENGINE CO.

The many friends and customers of the Buckeye Engine Co., Salem, Ohio, will be glad to learn that the item in the newspaper telegraphic news a few days since to the effect that their factory had been seriously injured by the recent cyclone is not true. The path of the cyclone was narrow and lay very near the Buckeye works, but that company fortunately escaped uninjured.

THE STANDARD UNDERGROUND CABLE CO.

After the first of May the New York office of this company will be found in the *Times* building, where more extensive quarters have been secured. During the past few years the enormous increase in the business of this company has made it necessary to twice double the capacity of its factories, but the present factories are still insufficient and the company has just broken ground at Brinton, Pa., for new factories which, it is claimed, will be, when completed, the most extensive wire and cable factories in existence.

THE SOUTHWARK, LONDON, UNDERGROUND ELECTRIC RAILWAY.

On March 5, the lord mayor of London, inagurated the Southwark electric railway which operates underground, including a tunnel under the Thames. The line has a double track, and current is led to the motor through an insulated conductor placed close to one of the rails, the return being through the rails and ground. There will be six stations for the completed line which extends from King William street to Stockwell, and a bill is now before Parliament for an extension of the line to Clapham.

THE FOREST CITY ELECTRIC WORKS.

Since the first of the present month the Forest City Electric Works, of Cleveland, W. B. Cleveland, manager, etc., have removed their factory to Geneva, O., where largely increased facilities will enable them to increase their outfit and keep up with orders.

....As a parting word to electric bell fitters and all who have anything to do with electric bells, I say, "Be thorough!"—*F. C. Allsop.*

.... If electricity is in reality a fluid, it might exhibit weight, could it be so isolated and condensed as to become sensible to our balances.—*Joseph Henry.*

....To protect the wires from mischievously disposed persons, let the two tubes be buried six feet below the surface of the middle of the high roads, and let each tube take a different route to arrive at the same place.—*Sir Francis Ronalds.*

.... An electrical engineer requires to know not only whether a current will be produced under certain circumstances, but also the exact effect of each one of these circumstances, so that he may be able to determine the conditions most favorable to its economical production, and design his apparatus and system accordingly.—*G. W. de Tunzelmann.*

THE CENTRAL AND SOUTH AMERICAN TELEGRAPH CO.

The Central and South American Telegraph Co. has just paid (April 8) a dividend of 1¾ per cent. The Mexican Telegraph Co. has declared a dividend of 2½ per cent., payable April 15 to stock of April 8. President James A. Scrymser of the Mexican company says the encouraging receipts of the present quarter (to March 31, 1890) tend to confirm the estimate that the business of 1890 will pay the usual 10 per cent. dividend on the new capital, $2,000,000, and leave a surplus equal to that of 1889. There are now in the treasury 874 shares of the company's stock and 1,634 shares of the Central and South American company. The balance sheet of the American company December 31, 1889, shows:

ASSETS.

Cost of Plant	$1,434,420
Duplicate cable, equipment, etc	395,034
Cash in bank	38,245
Bonds at cost	26,806
Stock at cost	127,450
Treasury stock at par	65,600
Open accounts	111,099
Total	$2,198,659

LIABILITIES.

Capital stock	$1,500,000
Invested revenue	110,913
Premium on treasury stock	16,560
Loan to C. and S. American Telegraph Co	40,000
Open accounts	95,962
Net revenue to December 31, 1889	435,223
Total	$2,198,659

Mr. Scrymser says of the Central and South American company that this quarter's receipts justify expectation of 7 per cent. on the increased capital of $4,808,000, and as large a surplus as that of 1889. There are now in the treasury 1,920 shares of capital stock. The repair steamer, "Relay," has been accepted from the contractors. The balance sheet of December 31, 1889, shows:

ASSETS.

Cost of plant	$4,351,603
Improvements	181,040
Cash in bank	230,833
Bills receivable	11,284
Investment securities	57,861
Temporary loan	40,000
Treasury stock	993,400
Open accounts	256,088
Total	$6,072,109

LIABILITIES.

Capital stock	$5,000,000
Invested revenue	476,043
Open accounts	11,538
Net revenue to December 31, 1889	584,528
Total	$6,072,109

THE McCREARY ELECTRICAL SPECIALTY COMPANY.

Mr. A. A. McCreary, of 18 and 20 Cortlandt street, whose well-known reflector for incandescent lamps has achieved such remarkable success, has been busy organizing the McCreary Electrical Specialty Co. which will carry on the industry he has built up in so short a space of time. One of the novelties it will bring out is a new patent switch for both arc and incandescent lighting, its feature of merit being the prevention of the arc that usually follows the opening of a switch.

With regard to the reflectors, it is worthy of mention that 500 of them have just been placed in the famous Corcoran art gallery, and are much admired by the Washingtonians. All the large companies are recommending the reflector and some orders from January yet remain unfilled. Mr. McCreary proposes to be up to date, however, in a few weeks.

MORE "COMBINATION" TALK.

The Boston *Herald* of April 11, publishes a remarkable special dispatch dated from Haverhill, April 10, in which it is stated a Villard syndicate is to take up some 120,000 additional shares of Thomson-Houston stock to be issued by the directors, and that this with other stock pledged to the scheme, will give the syndicate in question the majority control for which it has been seeking very anxiously. The dispatch thus concludes: "If this deal be consummated it will be one of the largest on record, and the question naturally occurs, What will become of the minority of stockholders? Will they be compelled to sell their holdings to the New York syndicate willy nilly, and, if so, at what price?"

The Clark Automatic Safety Device.—This ingenious arrangement has been designed by Mr. E. P. Clark, of the Clark Electric Co., for the purpose of avoiding the danger due to broken electric light circuits falling on metallic roofs or to the ground, where they are liable to come in contact with persons. By the Clark device, the instant the circuit parts, the dynamo is de-energized and current ceases. The action is so prompt that the opening of the line for even a fraction of a second stops the current. The automatic device has been arranged for series and shunt machines and continuous and alternating currents.

NEW ENGLAND TRADE NOTES.

MESSRS. S. C. NIGHTINGALE & CHILDS, the New England agents for the Magnesia sectional steam pipe and boiler covering, have received a contract to cover the main steam pipes, connecting pipes, drips, engine receivers, and feed-water heaters in the temporary power station of the West End Street Railway Co., Boston.

MR. F. E. PETTINGELL, of Pettingell, Andrews Co., of Boston, has returned from his trip to London, and brings with him a few English electric novelties. Though his trip at this time was ostensibly for the benefit of his health, it is satisfactory to learn that it was also profitable, Mr. Pettingell having arranged some important business while on the other side.

THE NATIONAL TELEPHONE MANUFACTURING CO., of Boston, have got out a very complete and interesting illustrated price list of their non-electric telephone apparatus. Their business in these telephones continues to increase rapidly, as they become better known. There is an extremely large field for such instruments, but at the same time there have been many failures of other acoustic telephones, and there is a certain lack of confidence in the minds of the public, which it is gratifying to know is gradually being overcome. The National company have several patents on their apparatus, and are well equipped to do excellent work, and to give satisfaction to intending purchasers.

THE TRIPP MANUFACTURING CO., of Boston, are at present engaged in building a double truck car for the West End Street Railway Co., of Boston. The car will have eight wheels, will be 28 feet long from door to door, 7 feet 3 inches wide, and 7 feet 9 inches in height from the floor, and will have seating capacity for 40 passengers. Each truck has four 30-inch steel wheels, and two 15 h. p. Thomson-Houston motors. The car will be provided with vacuum and hand brakes, and the brakes will be operated by a toggle joint arrangement, giving immense power. The Tripp patent roller bearings will be used throughout, and the car will be hung on trucks of an entirely new design, (on which patents are pending) the equalizing bar being connected direct to the journal boxes underneath, instead of passing around on top as hitherto. There are less parts and fewer bolts about the new Tripp truck than on any other form of truck, and they leave plenty of room for the application of the motors and electrical apparatus.

THE GETHINS ELECTRIC MANUFACTURING CO. are rapidly beginning to reap the benefit of their long experiments carried out by Mr. Gethins on batteries, and are coming to the front as one of the most important producers of reliable gravity batteries. The Gethins battery has been often and well described, and is now familiar to all consumers of gravity batteries, as reliable, cheap and durable. It requires almost no attention, no renewal of chemicals, and is absolutely constant, it being impossible to copperize the porous pot. The Gethins Manufacturing Co. are recently in receipt of large orders from the cities of Worcester, Pittsfield, Fitchburg, Portland, Ore., and Chelsea, the last named city having ordered for the second time, and reports go to confirm all the company claim for it.

THE TROPICAL AMERICAN TELEPHONE CO. report that the switchboard capacity at Caracas, Venezuela, is now full, and that business is growing with them in that country more rapidly than ever. The government have notified the American Telephone Co., Consolidated, a company which tried to usurp the rights of the Tropical company in Caracas, that their concession has been cancelled for non-performance of its conditions, no work having been done. Their shares are now offered at 3 per cent. of their face value with no buyers. The Tropical Telephone Co. has made an *exclusive* contract with William R. Grace and Company of New York, for Peru West Coast, under the recent Grace-Donoughmore concession by the Peru government. Mr. O. E. Madden, is at present in London negotiating the sale of the West Coast Telephone Co.'s business, and Mr. Charles Williams, Jr., is spending a few months with his family in Berlin.

THE WRIGHT ELECTRICAL ENGINEERING CO., of Boston, have contracted for the construction of a pole line of incandescent mains for the new Brush alternator recently supplied to the Haverhill, Mass., Electric Light Co. The line will extend from the central station to the centre of the city. They will also place the converters. The Wright company are also preparing plans and specifications for a 300 h. p. central station for the North Adams Gas Light Co. Provision will be made for at present three 45-light 1200 c. p. Thomson-Houston arc dynamos; and one 500-light Thomson-Houston alternating dynamo. The specifications will include two 150 h. p. Hazleton upright boilers, two 150 h. p. Fitchburg compound condensing engines, and Hunter clutches, pulleys and shafting. The Wright company have just finished wiring for 50 lights, using the "interior conduit" system, the house of Mr. W. A. Stiles, at Newburyport, a gentleman well known in electrical circles.

WESTERN TRADE NOTES.

THE KNAPP ELECTRICAL WORKS, 54 Franklin street, Chicago, are very busy filling orders for the well-known Grimshaw white core wires, tape and other specialties. They are also supplying large numbers of Perkins lamps for which they are special Western agents. These lamps have given good satisfaction wherever used, and show a remarkably long life and do not blacken.

MR. W. J. FLOYD, formerly of Boston, and well-known in electrical circles there has accepted a position with the Excelsior Electric Co. of this city and will take charge of the sales department. The Excelsior company and Mr. Floyd are both to be congratulated in this connection.

THE SPERRY ELECTRIC CO. are remarkably busy shipping their well-known dynamos to various parts of the country. The Sperry arc lamp is continuously in large demand. Mr. J. L. Kirland has joined the forces of the Sperry Electric Co. as electrical engineer, and his abilities will find there a large field.

COLONEL J. H. SHAY of the Charles Munson Belting Co., this city, has recently returned from a western trip with his pockets full of orders for their famous belting. Amongst others the following may be noted:—Denver Electric Illuminating Co., 100 feet 10 inch dynamo belting. Manitou Electric Light Co., Manitou, Col., 80 feet 10 inch dynamo belting. Pueblo Gas and Electric Light Co., 50 feet of 8 inch dynamo belting, South Denver Cable Co., 65 feet of 12 inch dynamo belting and the Kansas Ciiy Packing Co., 100 feet 30 inch double link, 272 feet 22 inch and 100 feet 20 inch double eagle. Truly Munson belting has found favor in the eyes of the electrical fraternity.

MR. GEO. FAIRBANKS, manager of the Chicago office of the Westinghouse Electric Co., is as usual busy looking after the interests and extensive sales of the company. He reports business to be in fine shape and prospects for the future very bright.

MR. W. A. SHELDON, general agent of the Schuyler Electric Co. was in town this week and called at the Electric Club.

MEETING OF THE EXECUTIVE COMMITTEE OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

The above meeting was called together at 11 o'clock A. M., at the Electric Club, New York, April 14, the following members being present: Mr. C. R. Huntley, Mr. Jas. English, Dr. A. F. Mason, Mr. M. J. Francisco, Mr. John A. Seely, Mr. Marsden J. Perry, Allan V. Garratt, secretary.

A letter was received from Mr. M. D. Law tendering his resignation, owing to removal to Denver. Mr. Law's resignation was accepted, and Mr. C. H. Wilmerding, of the Chicago Arc Light and Power Co., was elected in his place.

A communication was read from the Hon. Robert R. Porter, superintendent of the U. S. Census Bureau, thanking the Association for its hearty co-operation in the matter of electrical statistics.

Mr. R. W. Ryan was appointed official stenographer for the next convention.

In view of the fact that the present quarters of the Association will be required for other purposes on the 1st of May, a committee was appointed consisting of John A. Seely, James English and the secretary, to provide new headquarters for the Association.

The question of the legal rights of the Association to use an official seal, was referred to a committee of one, consisting of Secretary Garratt.

An entertainment committee of the five following members: F. T. Walton, A. J. DeCamp, J. J. Burleigh, John A. Seely, the Secretary, was appointed, with powers to add to their own number; to appoint sub-committees and to fix the date of the semi-annual meeting.

A committee of the following three members was appointed, to procure suitable papers for the next convention: J. E. Lockwood, of Detroit, C. H. Wilmerding, of Chicago, A. F. Mason, of Boston.

It was resolved that the secretary, under the advice and consent of the president, be empowered to contract for the placing of such advertisements as he can procure, to be published in connection with the report of the official proceedings, and that the price of the proceedings be made $1 for all applicants.

Secretary and Treasurer Allan V. Garratt tendered his resignation, to take place on the 15th day of June, 1890. Mr. Garratt's resignation was accepted.

The president nominated as secretary and treasurer, to take effect upon June 15th, 1890, Mr. Allen R. Foote, of Washington, D. C. Mr. Foote's nomination was ratified by the executive committee.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Vol. IX. NEW YORK, APRIL 23, 1890. No. 108

Nature is our kindest friend and best critic in experimental science, if we only allow her intimations to fall unbiased on our minds.—Faraday.

ELECTRIC RAILWAY EVOLUTION.

THE remarkable energy which has lately been concentrated upon the technical and commercial development of the electric railway has allowed but little time, if any, for the consideration of problems in which the future is involved. But the changes which have been brought about even during the past few years are, it would seem, but an indication of what may be expected to take place as time passes, and as both the designer, the electrician and the railway manager avail themselves of the experience of the near past. In considering the electric railway from the standpoint of the future, in a paper read before the Boston Electric Club, the author points out a variety of directions in which advances may with certainty be looked for, not only in details of apparatus, but also in general design and methods of operation. Among these the return to the single motor instead of the pair as now employed seems probable, and desirable, from more than one consideration, while the reduction of speed and a consequent elimination of a part of the gearing is also foreshadowed. Another important point touched upon is the application of the original electric locomotive drawing two or more cars, instead of the present car with its individual equipment of motive power. That the changes suggested under this head are by no means distant, was shown by the discussion on Mr. Wetzler's paper, in which Mr. F. H. Monks, general manager of the West End Railway, announced that his company were even now at work on the designing of an electric locomotive, in order to avoid the necessity of equipping a large number of cars which must necessarily lie idle during a considerable part of the time. Such changes as these are, of course, to be looked for more particularly in large electric car installations, but that their consideration is even now in order is evident.

ARC LIGHT MACHINERY.

THE production and exhibition of the first modern arc light system set to work immediately a host of inventors, whose entire energy was bent towards devising numberless ways of generating a constant electric current, and maintaining a steady arc. The results of this work early became apparent in the rapid progress of the art in a comparatively short time, and fortunately so, for the incandescent light, which soon after entered the field of practice, so absorbed the attention of electricians in turn that the arc machine has generally been neglected for some time past, so far as any systematic attempt at improvement or modification is concerned. Signs are not wanting, however, to indicate that a revival of interest in this direction may be looked for, and, in corroboration of this we need only point to the new Hochhausen arc light machine described elsewhere in our columns. The working out of the details of arc light machines involve considerations which are not present in the designing of incandescent machines, and which make the problem a somewhat more difficult one. As a consequence of these fundamental considerations, it is also impossible to attain the economy of material ordinarily reached in incandescent machines for a like electrical output in electrical horse-power. The new Hochhausen machine, however, compares most favorably with the latter in this respect. The details of its highly ingenious construction and regulation show that arc lighting, in skillful hands, is by no means incapable of important modification or improvement; and that even with the demands in other departments, time can be profitably spent on one of the earliest.

IS POLLOCK A BEAU IDEAL?

"THE highest ambition of a first-class Morse operator" once remarked Jack Selden of the old "House" telegraph line, "is to send stuff so that nobody can read it." It would perhaps be hardly fair to say that it was this sort of sending that carried off the highest prize in the recent telegraphic manipulative competition, but it is certain that the award was not made for excellence in the qualifications most essential in a commercial operator. Telegraphy is not a purely æsthetic pastime, like horse-trotting and billiard playing, inasmuch as the question of utility must receive some little consideration. The modern tendency in telegraphy, as in other industrial arts, is to sacrifice everything to speed and cheapness, but it is one which ought to be resisted rather than encouraged. The skill which has been acquired by the modern expert sound-reading operator has led to certain material modifications in the formation of the telegraphic characters, which are not only admissible but advantageous, if not carried too far. But old-fashioned "plain Morse" will never be without its uses, so long as paper tape-readers, and partly developed sound readers must necessarily constitute a large proportion of the aggregate number of persons engaged in the telegraphic service. It would seem, therefore, as if it would be wise, in formulating the conditions for these contests of skill, to see to it that legibility of transmission, and not speed, should be the *first* point to be considered, not only in certain classes of entries, but in all.

In this connection, we may call attention to the very bright and witty article that is contributed to our columns this week, by the well-known inventor, Mr. P. B. Delany, who, having behind him no mean record as a telegrapher, discusses the tournament in all its bearings, as a connoisseur, and brings out a number of new ideas. We believe that his views of the results obtained will commend themselves in the main, not only to the operators and the telegraph officials, but to those who like himself, have graduated from the key and can discuss the situation with the kindliest impartiality to all concerned. It will be observed, by the way, that Mr. Delany's careful analysis of the figures is highly complimentary to the skill of the ladies in the contest. Their beautiful sending was unquestionably one of the most encouraging features of the occasion.

Air as Insulation.

BEFORE the advent of the electric light the large majority of electricians were engaged in the telegraph or cable service, and hence it comes that the patent records of the time referred to contain many references to forms of insulation composed of a large variety of substances, but few of which are practically applied to-day. The insulation *par excellence*, dry air, was, of course, the standard which it was desired to approach as nearly as possible, but the nature of the materials employed evidently fell far short of this, and the use of air itself as the dielectric seemed impossible of accomplishment. The advent of the telephone and the frequent enforced burial of the conductors made it still more desirable to retain the air insulation of the overhead conductors, and constant efforts have been made to reduce the specific inductive capacity of the insulating materials surrounding such conductors. As an interesting approximation to air insulation for wires in the form of cable, we presented last week a description of the method employed by Mr. John A. Barrett. Although more especially designed for telephone work, this new type of insulation seems well adapted to other electrical service involving heavy currents, and we are not surprised to find that our note on the subject is attracting attention.

A New Electric Railway Enterprise.

THE appearance of the Westinghouse Company in the electric railway field is now definitely announced, and it is understood that work will be begun immediately. This is important news, and means greater activity than ever in this vast and extending department of electrical application. There will be considerable interest as to the form of apparatus adopted by the company. Rumors have been afloat for some time that it would introduce alternating current apparatus, but it may be opined that such will hardly be the case just for the present. As to direct current machinery, it will be open to the company either to produce original apparatus of its own, or to give new life and vigor to some system already known to the public. It may do both things, but whatever it does will be watched with the keenest interest on both sides of the Atlantic. One point is clear, and that is that 1890 will be a great year for electric street railroading in America. It will require 1891 to catch up to all the work developed, and in 1892 will begin the attack on the shorter steam railroads of the country.

Possibilities of the Telephone.

THOUGH the telephone has long since ceased to be a wonder, its great powers and adaptability to various purposes as yet but hinted at, must still command attention, very much on account of their commercial aspect. This is evident on contemplating the work done by this instrument in the installation at the Lenox Lyceum, by which the "Long Distance" telephone company has placed before the public an exhibit of superb qualities. It seems strange, indeed, that up to the present time, the telephone companies have not done more towards exploiting a field which could certainly be made a source of considerable revenue by the furnishing of musical and other entertainments by wire at the fireside. But still more impressive than the musical part is the remarkable clearness of the long distance transmission. Although we are all accustomed to ordinary local telephone transmission, the mind can yet hardly grasp the reality of the enormous progress which permits persons hundreds of miles apart to maintain perfect oral intercourse. Yet, we believe the time is not remote when even this will cease to attract even passing notice, and when the "long distance" lines, now mostly confined to the Eastern States, will cover the entire country with a vast net-work of "speaking-wires." The "Long Distance" company is to be commended for the liberal policy adopted by it, in educating the public to the proper appreciation of the facilities available for it, and, if we are not mistaken, it will date one of its quickest and longest strides forward from the display at the Lenox.

Electric Tube vs. Gas Pipe.

OUR New England representative makes note in his correspondence this week of the remarkable and interesting fact that the fine new telephone building in Boston, will not contain an inch of gas-pipe, and that in its place will be found the well-known "interior conduits," through which every wire, no matter for what service, will be drawn. It is true that there are buildings in this country already where no gas pipes are to be found, but we believe this is the first instance in which the electric tube has driven the gas pipe into exile. The incident is evidently one quite out of the common, and it will be interesting to see how quickly the practice thus inaugurated becomes common. The day of the "interior conduit" is certainly upon us.

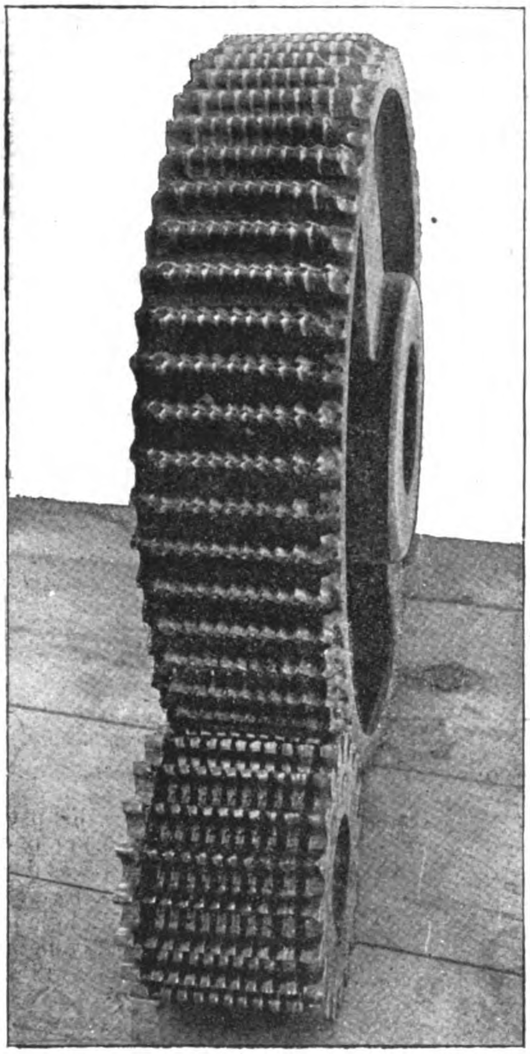
Sources of Rubber Supply.

THE statement is made by cable dispatch from Brindisi that on landing at that port and being interviewed, Mr. Stanley, the African explorer, divulged the important fact, which he had intended to mention solely in his forthcoming book, and that was that the Aruwimi forest, which belongs to the Congo Free State, was enormously richer in everything, especially in rubber trees, than the Amazon forests. This section of Africa, he declared, would be the rubber reservoir of the universe. In view of the extent to which rubber now enters into electrical manufactures, this news is encouraging as indicative of steady supply at moderate prices.

ELECTRIC CAR GEARING.

The gearing connecting the electric motor to the axles of the car has perhaps received as much attention as, if not more than, any single detail of electric railroading; and of the many devices contemplated and tried, the gear and pinion is the one most generally employed at the present time.

The ordinary practice is to transmit the power from the armature to the axle by four gears and pinions. The average car wheel and axle make about 115 revolutions per minute, to accomplish a car speed of 10 miles an hour. The intermediate shaft makes from 300 to 400 revolutions per minute, and the armature shaft from 900 to 1,200 revolutions per minute. This high speed means a rapid meshing of the teeth of the small pinions with the teeth of the gears.



Past experience, however, has shown that solid metal pinions meshing with solid metal gears produce a continuous metallic ring, increasing in volume with increase of speed; and to avoid this inconvenience, a composite pinion made of alternate layers of hard metal and rawhide, fibre or other non-resonant material, securely bound together, has been substituted very largely for the solid pinion. The disagreeable noise or hum was almost entirely eliminated, it is true, but another difficulty was developed in its place, which is vividly demonstrated in the accompanying engraving made from a photograph of a pair of electric car gears. The rapidly revolving metal parts of each tooth of the composite pinions, it will be noted, wear grooves into the faces of the teeth of the all-metal gears. Side play of the armature or intermediate shafts in some measure reduces the groove wear. The rapidly revolving small pinion, however, should wear away first; but in actual practice when the surface of the teeth of the all-metal gear is badly worn, a new gear must be substituted at the same time when the composite pinion is replaced. Solid pinions of metals other than iron are largely used to-day; they wear away more rapidly, and have the objectionable ring or hum, but, commercially, are considered of advantage. Among these, gun metal is preferably used, as also various compositions of a bronze nature. Solid steel pinions, with holes bored in the line of the axis and filled with lead, are also employed, the lead plugs being securely rivetted in position, so that they may not fall out when they become loosened after considerable service. This loosening takes place because of the peculiar compressibility of lead.

Solid fibre, specially prepared, is also found serviceable, but undue or excessive strains on worn, and even new, teeth have resulted in the breaking away of some teeth and the destruction of the pinion. Even pinions of layers of rawhide, compressed and glued together by adhesive compounds, are in service on some motor cars. Fibrous pinions are generally affected by the conditions of the weather, moisture being readily absorbed. Special precautions to treat the fibre or rawhide, however, lessen the influence of moisture.

The pinion and gear shown in the engraving have given a service of about 18,000 car-miles at an average speed of from 10 to 13 miles an hour. They were protected as well as possible from the dirt and dust of the road-bed by canvas truck coverings, but it is evident that the grit intermixed with the grease played a large part in the wear shown. The pinion was composed of rawhide and steel.

DEFINING "SECONDARY," "PRIMARY" AND "STORAGE" BATTERIES.

BY FREDERICK RECKENZAUN.

In The Electrical Engineer of April 9 is an article in which the author, Mr. E. R. Knowles, offers a definition of the terms "secondary," "primary" and "storage" batteries and "accumulators," the main object of which appears to be the exclusive assignment of two of these terms to a class of batteries which have thus far acquired comparatively little practical importance, namely, primary batteries capable of being regenerated by the action of an electric current.

While the selection of an appropriate designation for this class of batteries may be quite desirable, for the sake of distinction, it seems hardly advisable to borrow for this purpose from existing terms, the meaning of which has been so well established and so universally adopted. Whatever controversy there has been aroused, now and then, by the attempt to draw a distinct line between primary batteries on the one hand, and devices known as secondary or storage batteries, or electrical accumulators, on the other, the three last-named expressions have always been accepted as perfect equivalents.

In France, Germany, Austria and other countries, electrical literature avails itself of the terms "secondary batteries" and "accumulators" absolutely without an idea of distinguishing between them, the latter being the more generally employed where both are not used in conjunction. In England, and in this country, the same usage prevails, only the term "storage batteries" having been added as an equivalent which, although perhaps less appropriate from a scientific point of view, has found very ready acceptance in the language of practice. The desirability of having two or three terms to designate the same thing, may be questionable, but we find numberless precedents everywhere to disarm our objections. It is certain that confusion would be created by separating "secondary battery" from "accumulator" and "storage battery," to use the first named alone for the designation of the familiar device, while "stealing" the other *two* for the obscure object that so often furnishes the bone of contention when comparison is made between "primary" and "secondary" batteries.

If we are to have one term only for the latter, then let us drop the other two altogether,—although time may itself do the sifting—but do not let us make matters worse by lending the other familiar terms a new meaning.

If necessary, a new and more appropriate name could undoubtedly be found for that third class of batteries having properties of both the others; this would at least avoid stamping existing literature with confusion.

HENRY'S FIELDLESS MOTOR.

In the development of the modern dynamo and motor many hundreds of different patterns have been brought out, but through all of the designs it is not difficult to trace relationship between them and older members of the family. But a decided departure from the usual type is a form of motor recently designed by Mr. John C. Henry for street car work. This consists of a motor without fields, but having, instead, a plurality of armatures, with their brushes placed so as to cause a mutual action and reaction between the magnetic poles of the separate armatures. The object of the design is to make a machine of light weight capable of being self-sustained on a car axle.

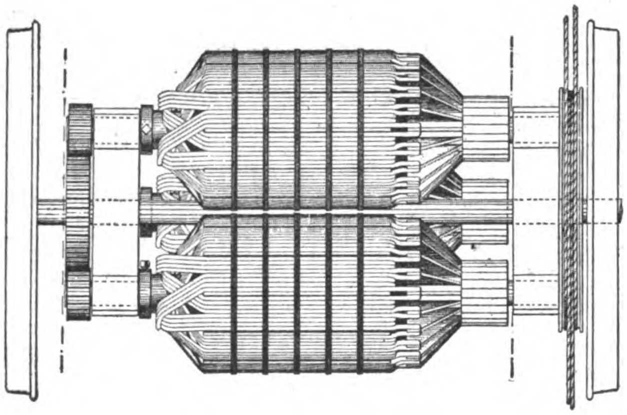


FIG. 1.

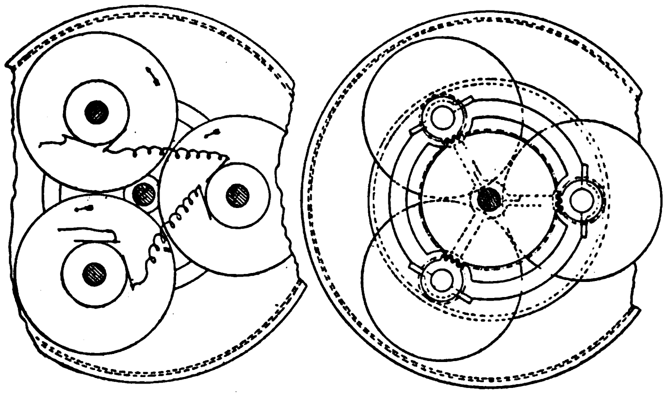
In the accompanying engraving, Fig. 1, are shown three armatures so mounted in a triangular frame, and supported loosely on a car axle. The armature shafts carry pinions which engage with a spur or internal gear which is keyed to the car axle, as shown in Fig. 2. On the opposite end a friction wheel is secured to the carrying frame. Around this friction wheel are placed wearing shoes and a cable which extends to the brake stems on the car platform.



FIGS. 2 AND 3.

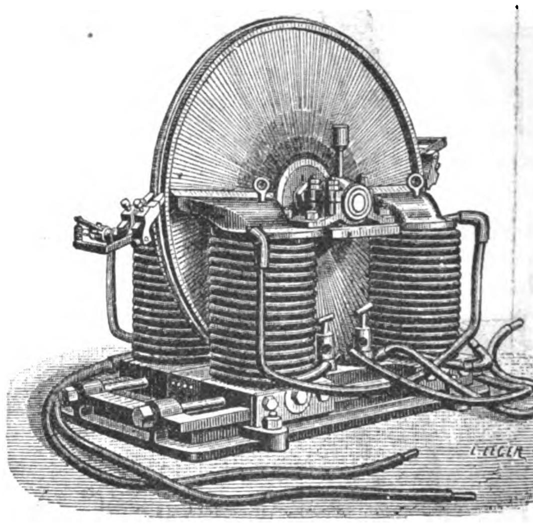
Ordinarily, under the influence of the current, the armatures turn around the car axle as well as on their own shafts, the former remaining stationary; but if tension is applied to the cable, the carrying frame is retarded or held stationary, and the car wheels are driven. By allowing the clutch to slip, the car speed is varied.

The illustration, Fig. 3 shows the arrangements of the brushes, which are placed 60 degrees apart, the armatures being connected in series.

We may add that the motor illustrated is now undergoing tests with both alternating and direct currents, and the results obtained are said to be very encouraging.

THE POLECHKO DISC DYNAMO.[1]

At a recent meeting of the Congress of Russian Naturalists, M. Polechko described a form of dynamo of the disc type, which involved some novel methods of construction. The armature of the dynamo, as shown in the accompanying engraving, consists of a single piece of metal, one metre in diameter, insulated from the shaft, and cut radially into 350 segments, separated from one another by fibre to within 13 centimetres of the shaft. The periphery of the disc is furnished with a steel rim, insulated from the disc itself, and widened out on either side of the disc, so as to serve as a collector.



THE POLECHKO DISC DYNAMO.

In the first machine, constructed after this pattern, with a magnetic field, equal in intensity to 6,500 C. G. S. lines, an E. M. F. of 25 volts and 2,000 amperes was developed at a speed of 1,500 revolutions per minute, its weight being 1,140 kilograms, (about 2,500 lbs). While more particularly adapted for electrolysis and electro-metallury, the inventor hopes to increase the voltage so as to make it applicable to electric lighting.

THE FRANKFORT, GERMANY, ELECTRO-TECHNICAL EXHIBITION OF 1891.

This exhibition will be opened on May 15, 1891, and will close on October 15. The exhibits will be classified under twelve sections:—I. Motors for electro-technical purposes. II. Generation of electricity. III. Conductors and auxiliary apparatus. IV. Accumulators and switches. V. Transmission of electric power. VI. Electric lighting. VII. Telegraphic and telephonic apparatus. VIII. Electric signaling. IX. Electro metallurgy and electrolysis. X. Measuring instruments. XI. Medical electricity. XII. Electro-technical literature. Applications for space must be sent to the executive committee before July 1, 1890. The delivery of exhibits which will require some time to erect may commence on March 15, 1891, and must be completed on April 15. Other exhibits may be sent in up to May 1. The charges for space are as follows:—A. Main building, 15 marks the square metre (about $3.25 per square yard.) B. Semi-covered space, 10 marks per square metre. C. Open air, 2 marks per square metre. The cost of insurance is to be paid by the exhibitors. The charge for power will be 3 cents per horse power hour, 3 h. p. being the minimum.

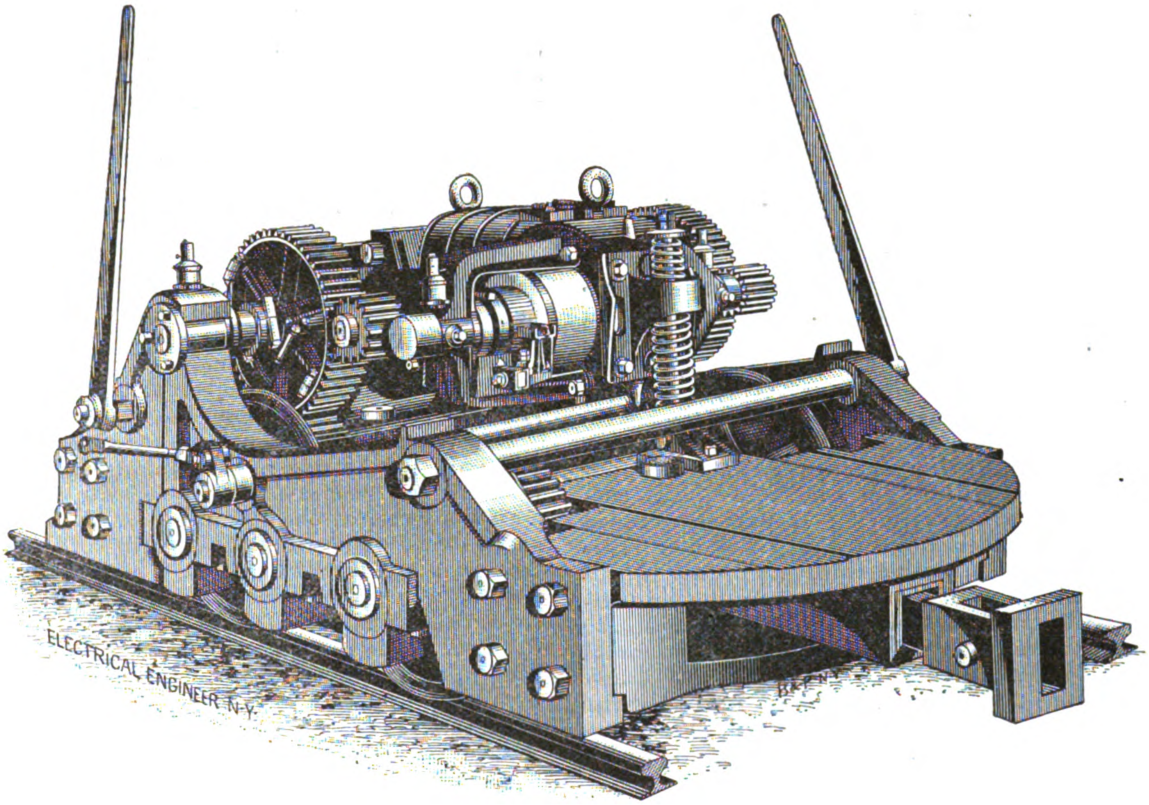
---

[1] *La Lumière Electrique.*

A SPRAGUE MINING LOCOMOTIVE FOR SWEDEN.

The attention which has been given to the application of electricity in mines has already evolved distinct types of apparatus for this class of work, which requires the fulfillment of some very exacting conditions. The application of the electric locomotive alone, for the propulsion of mining cars has called forth a variety of designs. As our readers are no doubt aware, considerable attention has been devoted to this branch of electric power application by the Sprague Electric Railway and Motor Co., and one of the latest products in this department of work is an electric mining locomotive which will shortly be sent to Stockholm, Sweden, to be placed in a mine.

The motor, which is illustrated in the accompanying engraving, is of 15 h. p., and of the standard railway type. It is hung in a method similar to that employed in street railway work, and includes the regular Sprague system of flexible suspension, but with the motor geared to both axles.



ELECTRICAL ENGINEER N.Y.

A Sprague Mining Locomotive for Sweden.

The electrical control of the motor is effected in the regular way by the use of a railway switch, which is placed on top of the box covering the motor, and which has handles on each end, so that the motor can be controlled from either end of the car. In the engraving the motor is shown with the covering box removed. There is also a brake lever at each end of the car, and the entire control of the car is effected by means of the electrical switch and brake.

The arrangement of the switch is such, that the motor can be run at any speed, from the slowest crawl to full speed, by varying the position of the switch through an arc of 150 degrees. The same switch reverses the direction of the motor and the car by moving the handle of the switch in the opposite direction.

The current is carried to the car by means of a single electric circuit, the underneath trolley contact being used. The draw bar is arranged to swing over quite a large arc, so as to accommodate the trail cars when going around curves. The gauge is 36 inches, wheel base, 26 inches, with the draw bar about 12 inches above the track.

TELEPHONY AT THE WOMEN'S EXCHANGE EXHIBITION.

The exhibition organized under the auspices of the Exchange for Women's Work at the Lenox Lyceum in this city, contains besides the exhibit of Mr. Edison's apparatus and the many beautiful lighting effects, another very noteworthy and interesting feature contributed by the American Telephone and Telegraph Co., who operate the long distance telephone lines which are now rapidly extending over the country. The exhibition contains what is probably the first systematic attempt to afford an opportunity for allowing a large number of people to listen to telephonic reproduction of a theatrical performance and the reproduction of musical solos and speech from a distant city.

As an example of what has been done in this direction we may note that every evening trumpet solos, singing and speech, direct and phonographic, are transmitted from Boston to the Lyceum a distance of 254 miles, in such a manner that 80 people are enabled to listen to the sounds at one time. That this is a remarkable achievement will be admitted when it is considered that besides traversing more than 500 miles of copper wire circuit the current passes through eight miles of cable. The articulation which we have had opportunity to test, is remarkably clear. This is specially noteworthy in the case of a transmission by a loud-speaking receiver which gives the sounds with remarkable purity and discernible easily by the ear at a distance of several feet.

Experiments have also been successfully tried in transmitting the reproduced speech by phonograph from Boston to Syracuse, via New York. This was accomplished on an evening devoted to the New York State Press Association when representatives of the press in the western part of New York were gathered at Syracuse and heard the sounds uttered in Boston.

Besides this remarkable exhibition of the power and possibilities of the long distance telephone and the long distance system generally, the public is also, with the aid of the Metropolitan Telephone Co., treated to an excellent exhibition of the manner in which the performances of theatres and concerts can be brought to their houses. For this purpose transmitters have been arranged at various theatres about the city, among them, at the Casino, where the "Grand Duchess" is now being performed. The plan adopted has been to distribute ten transmitters in the manner indicated in the accompanying diagram, Fig. 1. Four transmitters on each side of the theatre are attached to the boxes and faced towards the stage together with two in the centre of the house, as indicated. The primaries of each two transmitters are placed in series, and connected to two Fuller cells in series, while the secondaries of all the transmitters are connected in multiple arc to the lines running to the exhibition hall. Here there are receiving boards arranged in which the telephones are connected as shown in the accompanying diagram. There are four receiving boards arranged for the public, each board consisting of eight sets of five receiving telephones arranged in series as indicated in the accompanying diagram. This arrangement of placing the receivers five in series was shown after considerable experimenting to be the most advantageous with telephones having a resistance of 120 ohms. This, however, was only for the reception of local transmission; for the connection with Boston it was found more advantageous to place the telephones three in series instead of five. There are thus four boards of 40 receivers each, making 160 telephones which are able to receive transmission originating in New York at one time; while at the same time 13 sets of three each are arranged to receive from Boston. With the additional 'phones on the line there are altogether over 200 receivers connected. This is probably the largest number which has yet been employed in the simultaneous reception of telephonic transmission.

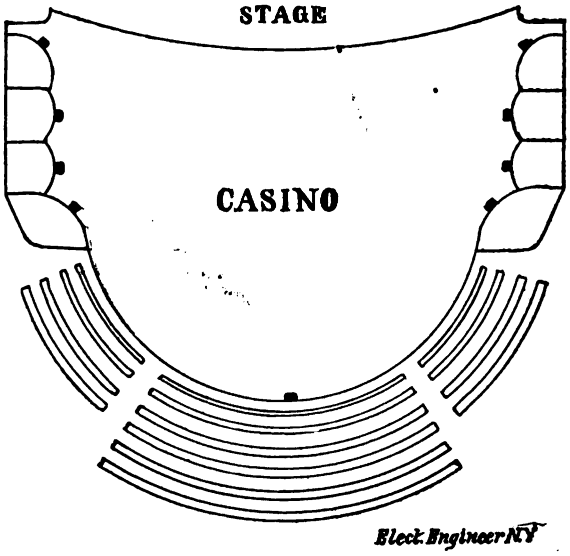


FIG. 1.

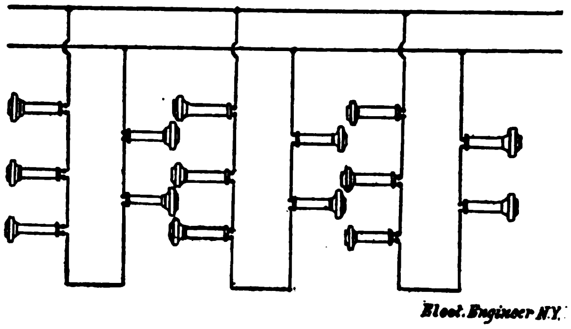

FIG. 2.

The work accomplished here has been of the most thorough kind. Every connection of the switch-board was soldered and okonite wire was employed throughout. There is also a mechanical switch-board employed for the purpose of changing over from one theatre to another, and for throwing in circuits connected to various exchanges.

The installation deservedly attracts a large share of the attention of visitors, many of whom remain for hours listening to the beautiful strains and recitations which come over the line during the entire evening.

The arrangements of the details of this interesting exhibit have been carried out by Messrs. A. S. Hibbard, J. C. Hovey and F. A. Pickernell of the "Long Distance" Co., and the results obtained are in the highest degree satisfactory, proving that the telephone, and especially the long distance telephone, can be made to fill a sphere of usefulness which is but little realized at the present time. The exhibit is nothing short of a revelation, as well to the electrical engineer as to the average citizen.

THE NEW HOCHHAUSEN ARC LIGHT MACHINE.

THE various systems of arc lighting employed have seen comparatively little variation in the form of the dynamo employed in the past few years, and, indeed, it had almost come to be taken as an accepted fact by many that few changes would be seen in the near future. That the industry is, however, by no means one incapable of improvement and modification in apparatus as different needs become apparent, is evidenced by the fact that a machine of decidedly novel type is now ready to be placed before the public.

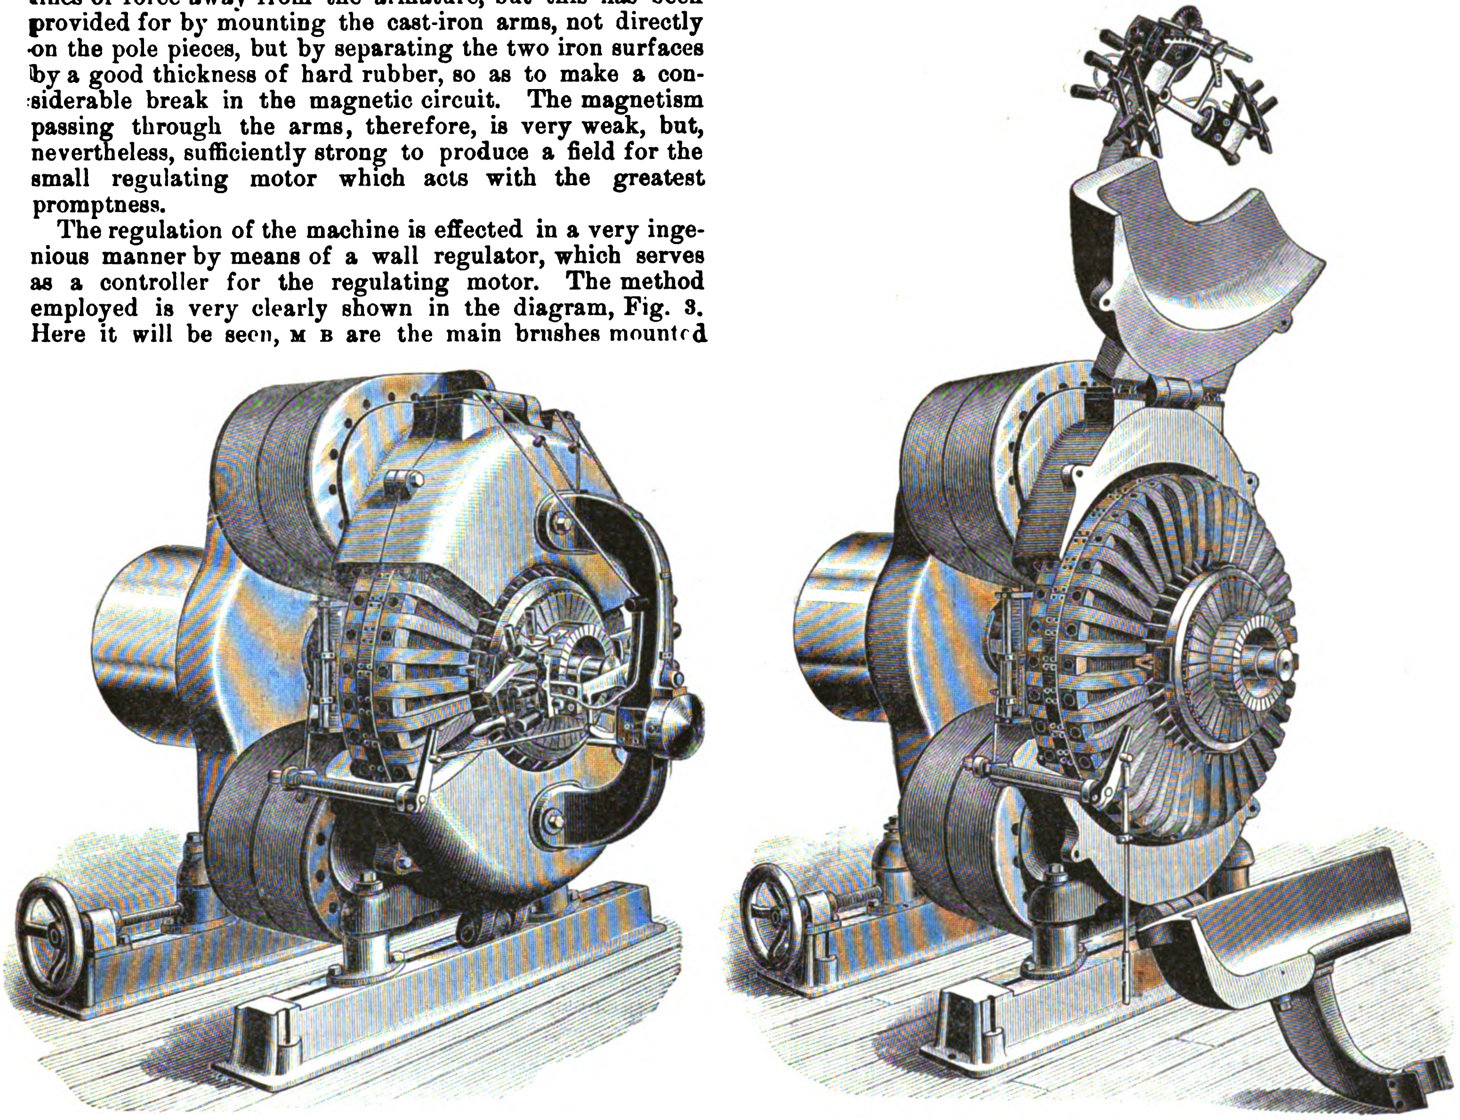
The designer of this new machine, Mr. William Hochhausen, electrician of the Excelsior Electric Co., was among the first to engage in the arc lighting industry, and is the inventor of various types of machines. His last effort in this direction embodies his mature experience, and as such, presents a considerable number of interesting departures from the type of machine at present in use.

Beginning with the magnetic frame of the machine, it will be noted by referring to the accompanying illustration, Fig. 1, that it consists of two field cores connected by a cast-iron yoke at one end and provided with pole pieces at the other, which encircle the armature on three sides. The armature, it will be noted, is so placed that its shaft rests in bearings which are on the interior of the machine, so that the armature, as exhibited in Fig. 2, can be entirely exposed. This is facilitated by the pole pieces which are hinged, as shown, and which can be turned out so as to expose the armature completely, and allow it to be drawn out a sufficient distance for thorough repair, if necessary, without removing the shaft from the journal bearings.

The armature core is built up of iron wire, insulated by paper, the wire being wound on a cast-iron frame or skeleton having a T section which divides the core into two parts. The arms of the spider which holds the armature are insulated from the core and frame, and fit into notches which are cut tapering from both sides towards the centre, so as to keep the whole concentric.

The coils of the armature which are rectangular in section, are wound automatically upon the core by an ingenious machine devised by Mr. Hochhausen for that purpose. When placed upon the armature core the coils are separated on the outer circumference by wooden wedges, which are secured to the cast-iron skeleton of the armature, and they are held in position by sections of fibre band which are screwed into the wooden wedges just referred to.

The regulation of the machine is a development of the methods heretofore employed by Mr. Hochhausen and is very ingeniously carried out, consisting both in the shifting of the brushes in conjunction with a regulating resistance, both of which are simultaneously operated by an old device originated by Mr. Hochhausen, namely, a small auxiliary motor. This motor which is entirely hidden from view is situated in the hub-like projection bearing on the arms which span the two pole-pieces beside the end of the armature shaft and which might be mistaken, except on closer scrutiny, for the bearing of the shaft. This small motor is fixed in a magnetic field, which is produced by attaching the cast-iron arms shown to each pole piece and bringing them together so as to surround the armature of the small motor. It might be thought for an instant that such a bridging of the magnetic circuit would take a large number of the magnetic lines of force away from the armature, but this has been provided for by mounting the cast-iron arms, not directly on the pole pieces, but by separating the two iron surfaces by a good thickness of hard rubber, so as to make a considerable break in the magnetic circuit. The magnetism passing through the arms, therefore, is very weak, but, nevertheless, sufficiently strong to produce a field for the small regulating motor which acts with the greatest promptness.



Figs. 1 and 2.—The New "Excelsior" Arc Light Machine.

The regulation of the machine is effected in a very ingenious manner by means of a wall regulator, which serves as a controller for the regulating motor. The method employed is very clearly shown in the diagram, Fig. 3. Here it will be seen, M B are the main brushes mounted upon a rocker arm which is provided with a circular rack which meshes with a pinion attached to the end of the shaft of the small motor regulator.

Starting from the positive terminal of the machine, P, the current is led to the binding post 4, on the wall controller and from there passes into the controller magnets, M M. After traversing these magnets the current enters the armature, A, and after passing through the resistance, R^1 goes to line and the external circuit to the negative terminal N, and main brush of the machine.

It will be noted, however, that the end of the controller armature A, bears against two contact points C C^1, which are connected through points 2 and 3, to the brushes of the small regulating motor on the machine. At the same time the two latter circuits are tapped at points P^2 and P^3, and connected through German-silver resistances, R^3 and R^2 to the terminal 1.

Now the regulating magnet, M M, is so adjusted that when the normal current passes over the line, the armature A stands horizontal and makes contact with both points C C^1, which are fixed at the end of the lever B. The current entering the armature A from the magnets M M, therefore, besides passing to line through the resistance R^1, has two other paths open to it, through contacts C C^1, to the brushes of the small regulating motor via points 2 and 3. But it will be remarked that the currents in these two circuits are in the same direction and when they meet at the regulating motor oppose each other, with the result that they have no effect on the little motor, the armature of which remains stationary. It will also be noted that a part of the regulating current passes to line through R^2 and R^3.

Now, if from any cause an increase of current takes place above the normal, the armature A of the wall controller is drawn down out of its horizontal position, by which action the contact at C is broken, while that at C^1 is still maintained. The regulating current now has only one path open to it from C^1 to 2, 2, etc., to the left hand brush of the motor regulator, thence through the armature to the other brush to points 3, 3, P^3, and out to line through the resistance R^2. This affords a complete and continuous path for the regulating current, and the motor armature at once starts to revolve and to turn the brushes of the machine in the corresponding direction for cutting down the current; at the same time the rod FF acts upon the field switch S, which assists the brushes in reducing the current by cutting out sections of the field magnets.

When the normal current has again been established the controller armature re-establishes contact, C, and the regulating motor stops. A diminution of the current from the normal causes the breaking of the contact, c^1, which sends the regulating current through the motor in the direction opposite to that just described, and with a corresponding effect. It will be evident that at all times the resistances R^1 R^2 and R^3 are in circuit, and as the last two points form constant shunts to the points C and C^1, no sparking whatever takes place when contact is broken at either of those points.

The result of this is, that upon any variation in the current, not only are the brushes revolved in a corresponding direction by the regulating motor, but, as will be noted, the field switch S is operated, to cut sections in or out, by means of the connecting arm F F; both these methods of regulation acting in conjunction serve to bring the machine instantly into its normal state.

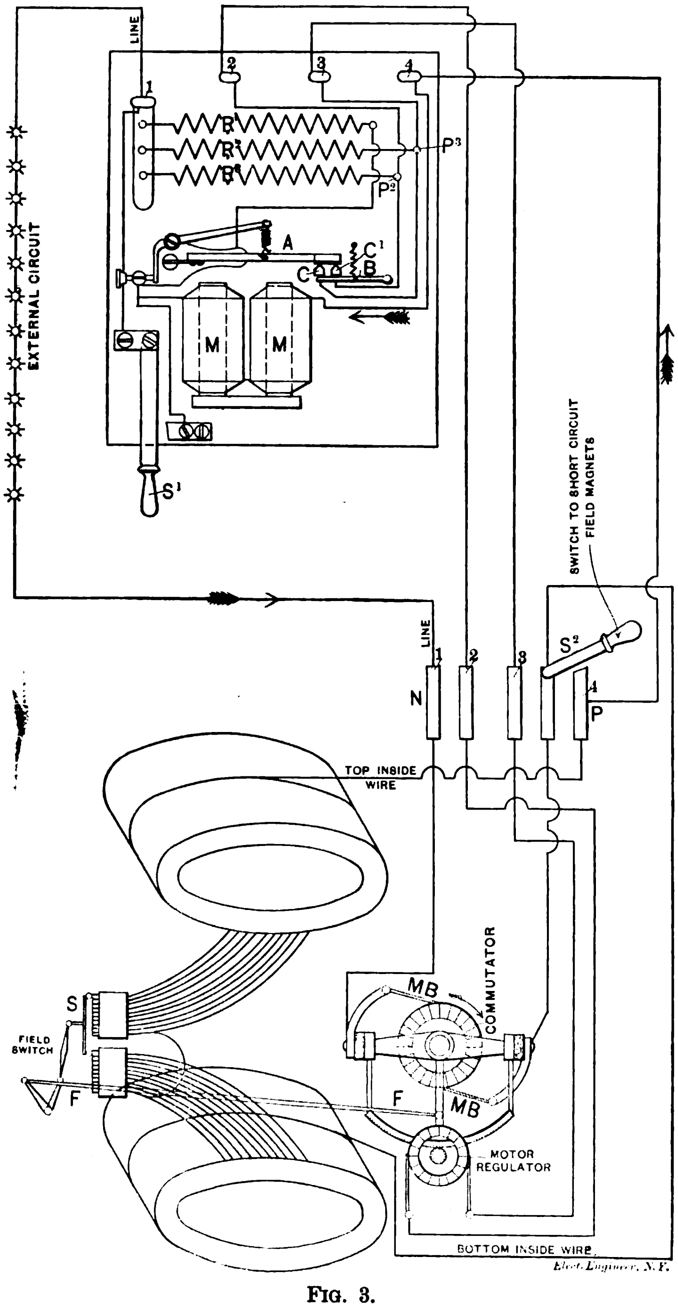


FIG. 3.

An experiment which we witnessed with the machine fully demonstrated the reliability of the device, even when the full complement of lamps were thrown on and off instantaneously.

The switch s^1 is provided for the purpose of cutting out the regulating motor when adjusting the position of the magnets M M; while the switch s^2 is employed for short circuiting the field magnets when shutting down the machine.

As the potential employed on the largest sized machine approaches the neighborhood of 5,000 volts, extra precaution must be taken for insulation of the various parts, which is made especially necessary by the static charge which has opportunity to accumulate from the friction of the belt. The jumping of the spark due to this accumulation is apt to be followed by the current from the machine. To avoid this the armature is thoroughly insulated with mica from the spider which holds it and the bearings are also insulated from the main body of the dynamo, and the latter again from the iron skids upon which it is mounted.

Various sizes of this machine have been built, the largest, designed for 125 1,200 candle power lamps, or for 100 2,000 c. p. lamps. The diameter of the armature of this machine is 30 inches and has 36 coils wound upon it, each eight inches square. 160 pounds of No. 17 B. & S. wire are wound on the armature for the 1,200 candle power lamps, which require seven amperes, and the same weight of No. 16 wire, where the 2,000 candle power lamps are employed, which take 10 amperes. The speed of the machine is 700 revolutions per minute and its total weight 5,500 pounds.

The field is wound with 1,300 pounds of No. 8 wire divided into two sections. One of these is wound unbroken, while the other is tapped at equal intervals by 20 wires which are connected to the field switches and controlled by the brush rocker in the manner described above.

The second size of this machine constructed is designed for 50 lights of 2,000 candle power each and has 90 pounds of wire in the armature and 870 on the field. The third size, designed for 30 lights, has 55 pounds of wire on the armature and 400 pounds on the field.

The general appearance of the machine, it will be noted, is exceedingly compact and the open construction adopted allows of ready access to every part for examination and repair, if necessary. The machines have already been placed in several stations where their operation has been attended with marked success.

GUTTA-PERCHA-COVERED WIRES IN CEMENT CONDUITS.

In an article in the *Annales Telégraphiques*, M. Scheffer, in describing the repairs which he has lately been carrying out on the subterranean lines in Maurienne (Savoy), calls attention to the deterioration of the gutta-percha insulation of wires laid in cement conduits. "The gutta-percha is in most instances impaired, and in consequence the thickness of the dielectric is no longer sufficient to prevent disruptive discharges where high-tension currents are employed." The wires in question were laid in 1885.

SPECIFIC INDUCTIVE CAPACITY OF RAREFIED AIR.

In a recent paper[1], Dr. James Moser, has shown that, while air rarefied to the extent common in Geissler tubes, is a conductor, a high vacuum is really an insulator. It was of interest to determine the specific inductive capacity of air in these two states, and with this view a Leyden jar was constructed with air as the dielectric. A Geissler pump was placed in communication with the condenser, and also with Dr. Moser's double vacuum tube already described. The former was used to rarefy the air, and the latter, when excited by an induction coil, to indicate by its appearance the state of rarefaction. Both were disconnected from the condenser when the capacity measurements were taken. A Mascart-Carpentier electrometer was used, whose capacity was comparable with that of the air condenser. The quadrants were charged with a Latimer Clark's cell, and the needle by commuication with the air condenser, which had been previously charged by means of a Zamboni pile. The deflections produced should vary with the specific inductive capacity of the rarefied air, since the potential of the Leyden jar must fail, on being connected with the needle, by an amount depending on the ratio of the two capacities. The results obtained by Dr. Moser were, however, negative, no certain variation in the deflection being estalished.

. . .THE first requisite for an observer is that his mind should be actively awakened to the phenomena of nature with which he is surrounded.—*Joseph Henry.*

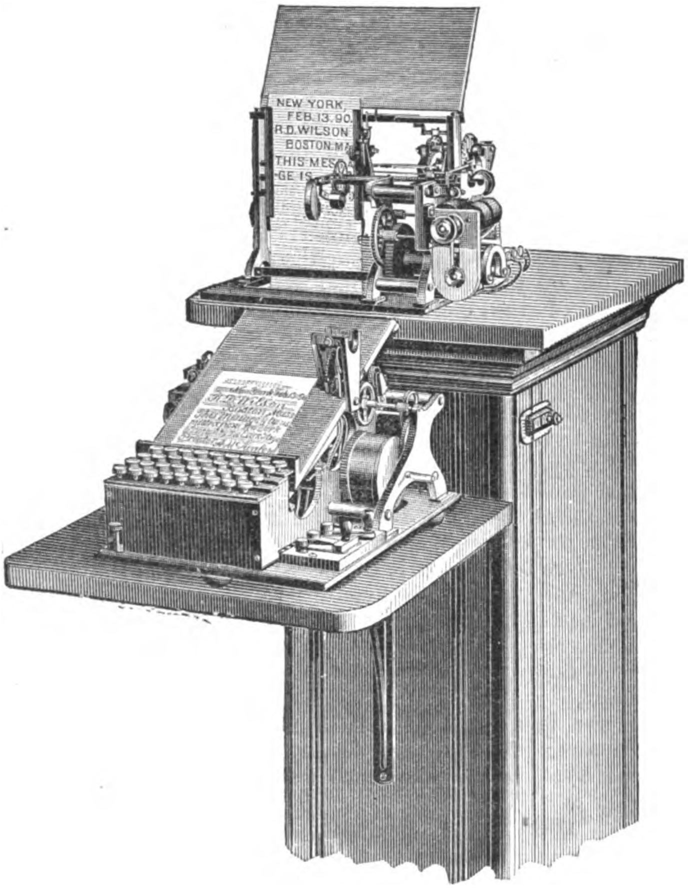
[1] THE ELECTRICAL ENGINEER, April 9.

THE ESSICK PRINTING TELEGRAPH.

There is now in daily operation between Boston and this city a system of printing telegraphs, the invention of Mr. S. V. Essick, which possesses a number of novel features, and is intended to place in the possession of brokers, merchants, and the public generally an instrument, which, while combining the well-known features possessed by the usual printing telegraphs, has additional advantages which make its use very convenient.

Printing telegraphs have, as a rule, been associated with the employment of a long tape upon which the news is received, and which for reference frequently requires the going over of many yards in order to obtain the information wanted; at the same time the length of a message of any considerable extent is inconvenient, and for filing purposes the tape is evidently an awkward arrangement. In the Essick instrument this has been overcome by an arrangement very clearly illustrated in the accompanying engraving. Instead of employing the tape heretofore used, a paper roll is employed having a width of 4½ inches, upon which the letters are printed in lines the width of the roll, so that they can be read in the same manner as a page of ordinary print.



The Essick Printing Telegraph.

The instrument, it will be seen, consists of a receiver which is operated by impulses received from the line through a polarized relay which operates a type-wheel. Fourteen impulses represent the entire alphabet, making a complete revolution of the type-wheel, which is capable of turning 200 revolutions per minute, and by which it is claimed 50 words a minute can be printed.

The roll of paper, which is continuous, is held in a frame which travels one space for each letter printed, and at the end of the line is automatically shifted back to the beginning of a new line, and at the same time advances the space dividing two lines. The operator handles a keyboard, so that any one can in a very short space of time become conversant with the operation of the instrument, and which therefore requires no special operator for its working.

In this new system the impulses move the instrument, and operate at the same time all the other instruments on the line. Any break in the wire, therefore, opens the circuit, which entails the breaking of the communication, so that the operator immediately becomes aware of it. The system, it will be seen, is so arranged that the transmitting operator records the message, not only at the other end of the line, but also at his own instrument, so that there is constantly available a copy of all the messages sent. The duplicating of the order transmitted by the copy at the transmitting office is evidently a valuable feature in many departments, especially in railroad work, as it affords a check upon all orders transmitted.

Any number of receivers can be placed on the circuit and operated by a single transmitter so that news can be sent to various places at the same time. A single line is employed in transmission and we have recently had occasion to witness the work of this instrument between this city and Boston, the result of which proves the same to be a valuable addition to the present methods of communication.

The system is now being operated by the Essick Printing Telegraph Co., of this city, and has been brought to the attention of the Congressional Committee now investigating postal telegraph facilities.

"MUNICIPAL" LIGHTING AT MARQUETTE, MICH., AND BANGOR, ME

The following table shows the lamp capacity of plant and lamps in use during the month of January in Marquette, Mich.:

ARC LIGHTS.

Capacity of arc dynamos, 124 lamps

Used for street lighting	60
Used by private consumers	22
Used at power station	1
Total	83
Remainder yet available	41

INCANDESCENT LIGHTS.

Rated capacity of dynamo, 750 16 c. p. lamps.

Number of lamps in use, all candle powers	769
Total number on 16 c. p. basis	837
Excess over rated capacity	88

The following table shows receipts from all sources for January:

From city, 60 arc lamps	$200 00
From private consumers, 22 arc lamps	128 00
From private consumers, 727 incandescent lamps	247 32
From water board and city, 32 incandescent lamps	4 68
Total	$580 00

The cost to the city for operating the plant and interest on bonds issued to establish it were as follows, for the month of January:

Wages, engineer, assistant and trimmer	$185 00
Carbons	40 00
Oil, waste and fuel	15 00
Repairs, breakage and incidentals	35 00
Interest	166 66
Total	$441 66

The plant is still capable of furnishing 41 more arc lights, which at $6 per month amounts to $246 more. The incandescent dynamo can carry 173 lamps more, which would bring in from $100 to $150 more per month.

A "VOTER," in writing to the Rutland (Vt.) *Herald*, says "Below is a sample of how villages are deceived regarding the cost of putting in electric light plants, to be operated on municipal account, and Bangor (Me.) is selected as the instance. Its city charter enables it to use certain water power. Assuming this power to be sufficient, an estimate was made of $17,000 to equip the city with a plant of its own, and afterwards $3,000 was added for contingencies, whereupon the city committed itself to the scheme. The lowest bid received, however, was reported at $26,000. The water power was found inadequate, requiring a steam plant in addition, costing $5,000, and an additional $10,000 is now required to make the plant answer the city's needs, or in all, $41,000, as against the estimate of $20,000 on which action was first based. Do the taxpayers of Rutland want to be burdened with more taxes for a wild scheme of this kind?"

THE TELEGRAPHERS' FAST SENDING TOURNAMENT.

BY PATRICK B. DELANY.

As there are forty or fifty thousand people talking about the young Yankee Pollock, who brought his bundle of thews and nerves down from a Connecticut town, and coolly stretched the record out of reach at the fast sending tournament, we might as well see what this cheeky manipulator really did. In his first trial he poured out a stream of dots and dashes to the tune of 51⅘ words per minute, and then, like Mark Twain's coyote, when his speed was questioned, let out another link in his backbone and shoved the record up to 52 words per minute, making 260 words in the five minutes given to each contestant. It is claimed, and with some reason, that the work was not plain and perfect. I know that the sending of Messrs. Gibson, Ayres, Waugh and Bradt was vastly superior as to quality, and of such a character as not to fly off the poles in turning sharp angles; but still, I think the "Yankee Blade" made all the signals, and that the lack of clearness so noticeable, was, in a great measure, due to the great speed, and his lightness of touch.

It has been the custom heretofore for commercial operators to turn up their noses at the railway operator, and Pollock seems to have made up his mind to avenge the slights and indignities so long and lavishly heaped upon his train-guiding brethren. Admitting that his juggling of the signals had many of the characteristics of a railway accident, still, every time I caught the thread of his discourse I found him putting it all in honestly. I couldn't follow him all through. Even the air-brakes seemed powerless to hold him. He was a sort of runaway train going down grade, and if the time-keeper hadn't opened the switch on him, there is no telling where he would have fetched up. Now, if Pollock, Jr., made all the signals, I claim that, regardless of classicality, he has performed a wonderful feat, and I am strongly of the opinion that so great a number of impulses, of any kind, have never before been made in the same time.

I have been experimenting a little since the tournament, with a view of ascertaining whether, if Mr. Pollock had made all dots, he could have crowded any more into his record than the number of mixed dots and dashes credited to him; and I have come to the conclusion that the almost infinite number of changes involved in the transmission of the English language by dots and dashes is restful to the operator, and that if he were compelled to make the letter "p" or figure "6," consisting of all dots, at top speed, for five minutes, his muscles would be practically paralyzed. It is easily tried. Others may find it different.

Since Fast Sending Tournaments promise to increase in interest from year to year, I have no doubt that certain improvements will be made in their arrangement which will contribute to the speed of the operators and to the certainty of decisions by the judges. Nothing was plainer than the consideration and fairness of all connected with the tournament just closed, but when writing climbs up into the fifties, it becomes very misty, and faults are difficult of detection. I have many times tested the limit of sound reading by using a punched strip and machine transmission. Sixty to sixty-five words per minute can be followed, if the matter be familiar to the ear, or with the manuscript before the listener, but this must be from a strip carefully punched. I think therefore that a Wheatstone recorder should be used for receiving the writing of each contestant. This instrument, properly adjusted, will record over 500 words per minute, so that there need be no fear of anything being missed. I would suggest also that a condenser be used to prevent sparking at the key points, especially if a considerable number of sounders are to be used in the circuit. It occurred to me and some others that one first-rate sounder placed in the centre of the hall would be more satisfactory than a number scattered about, some well adjusted, others not. With a single sounder there would be a unanimity of opinion regarding the quality of the work.

An analysis of the real meaning of Pollock's wild flight is interesting. It shows that the 260 words transmitted in five minutes call for 1,223 letters and 11 punctuations, or say 1,234 letters in all. To make these letters 2,834 impulses were required. This puts over nine impulses into each second, and as each impulse calls for a down and up motion of the key, the hand and fingers of the "Railway Guide," from Hartford, had to make nearly 19 movements per second for 300 consecutive seconds. If any one thinks he carries more agility than this about his person, fame awaits him—if he is not mistaken.

I doubt very much if there be any one living able to write out words at this speed. Forty-five words per minute will claim any man's undivided attention, so that until the penmen can put more steam into their fingers, Pollock's gait would be useless, even if it could be maintained—which it could not. It is fair to assume, however, that a man who can do 52 words per minute in any shape, might send grandly at the rate of 45 words per minute. If the elder Catlin's pace and beautiful style of transmission were general throughout the country and there were receivers to put it down, the earning capacity of the telegraphs would be just about doubled. Here is something for managerial meditation. There is money in it. When a boy like young Catlin, not yet old enough to vote, can double the work of an ordinary circuit, he becomes a duplex. He should be encouraged.

To my mind the great speed and general excellence of the work of the young women, was the most remarkable feature of the contest. It was a revelation to one who has not been very close to the sounder for some years. I considered 32 or 33 words per minute the winning speed in their class, but how the glory of old times faded when 43 and a fraction were poured out with ease and grace without untying a bonnet string. I think the quality of the young women's work averaged higher than that of the men.

I find that there are 636 dashes in the 260 words sent by Pollock, or an average of about one dash to two letters. Five letters to a word is the usual way of reckoning. If Pollock had to furnish five letters to a word, his score would be 246⅘ words. But 4¾ to 4⅞ is nearer the average. This may be proven by counting the letters and words in a few columns of the editorial page of the New York *Sun*, any day.

In the first 50 words of the 260 there are 600 Morse characters; in the second 50 words, 566; in the third 50 words, 531; in the fourth 50 words, 532; in the fifth 50 words, 503, and in the 10 words which distinguished Pollock, there are 102 characters. There is a difference of 97 characters between the first 50 words and the fifth. This is equal to five words. As young Catlin sent 251 words and one letter, or 2,738 characters, he is just 96 characters behind Mr. Pollock.

Here is what was done by each contestant,—the names being in the order printed on the official programme.

Ladies' Class.

	Words.	Characters.
Millie Moss	191-4	2,156
T. V. Froschel	200-5	2,241
B. M. Dennis	212-4	2,328
K. B. Stephenson	217	2,367
Annie M. Schaffer	193-2	2,176
J. Schlesinger	207	2,296
E. V. N. Garthwaite	201	2,245
M. C. White	169	2,003
L. Wagner	185-4	2,096
A. E. Findley	193	2,170
M. A. Daley	186-1	2,099
E. R. Vanselow	210-4	2,327
S. C. Barry	197	2,196

Old Timers.

	Words.	Characters.
J. H. Dwight	138-7	1,553
Fred. Catlin	217	2,367
A. S. Ayres	229	2,514
G. M. Eitemiller	197-4	2,215

Class A.

	Words.	Characters.
A. J. Swan	215-2	2,342
F. L. Catlin	241-1	2,635
F. L. Catlin (second trial)	237	2,602
H. S. Wright	203-2	2,267
H. D. Paulhamus	218-7	2,391
W. L. Waugh	229	2.515
J. P. Bradt	224	2,464
W. Davis	195	2,187
W. Davis { 2d trial on acount of time error. }	194	2,175
M. H. Toomey	230-4	2,530
J. W. Roloson	248-3	2,707
J. W. Roloson (second trial)	246-2	2,682
R. B. Pollock, Jr	258	2,811
R. B. Pollock, Jr. (second trial)	260	2,884
W. M. Gibson	239	2,622
W. M. Gibson (second trial)	238-4	2.617
U. Peters	217-2	2,411
F. J. Kihm	238	2,609
G. W. Simmonds	221-1	2,446

Class B.

	Words.	Characters.
W. L. Waugh	229	2,515
Ed. Bishop	193-3	2,178
J. G. McCloskey	209	2,305
A. J. Swan	212-8	2,354
Frank English	225	2,471
H. S. Wright	211-1	2,334
D. Wark	224-1	2,464
H. D. Paulhamus	224-1	2,464
M. J. Doran	213	2,359
M. H. Toomey	228-6	2,510
F. L. Catlin	251-1	2,738
R. C. Mecredy	220-2	2,442
W. A. Jones	223	2,461
O. Hart	222	2,456
J. P. Bradt	220-2	2,447
C. W. White	218-8	2,429
A. S. Patterson	201-4	2,248
J. D. Hinnant	214	2,356
F. F. Norton	211	2,333
E. A. Sprong	208	2,256
W. Davis	193	2,170

There were 13 women and 34 men in the contest. Taking the highest figures of each contestant they foot up a total of 9,955 words transmitted, or an average of nearly 42⅓ words per minute for each of the 47 operators. The women averaged 39⅜ words per minute, the men 43⅓. All praise to the ladies. Great is Pollock.

THE EVOLUTION OF THE ELECTRIC RAILWAY.[1]

BY JOSEPH WETZLER.

The theory of evolution, as now generally applied to organic life, has reached a point of development where it may be considered to have almost attained to the position of established permancy, and which the many facts adduced all tend to strengthen. While the theory is applied to man, in so far as his bodily organism is concerned, it may be claimed to go further, and I think it cannot be difficult to trace its processes not only to the whole organism, but to the products of his brains and hands as well. Every step in advance now recognized as of benefit to mankind has been the result of an evolution of thought combined with an evolution of practice. Take for example, the steam engine. What changes has it not undergone, and what form has it not assumed since the day of Watt? Consider, if you will for a moment, the various types into which it has differentiated, each of which is best adapted for certain conditions, localities and circumstances, quite analagous, indeed, to the way in which Darwin and Huxley have pointed out the variations which changes of locality, climate and proximity to natural enemies have brought about variations in the animal species. To this general evolution which is constantly going on both in the material and the spiritual world, the electric railroad is no exception.

In order to be logical, let us briefly refer to the past for the purpose of making our record complete. History tells us that as far back as 1835 attempts were made at electric locomotion, and for 40 years spasmodic efforts in this direction can be traced through the annals of electricity, including the work of a number of men, among whom American inventors are by no means the least conspicuous. What were the elements in these early locomotives? They were, first, the electromagnetic motor, and second, the primary battery. The combination of these two crude, or, as we may say, rudimentary elements, was evidently not calculated to bring the electric railway into the field of practical use. Nevertheless, they were a starting point, and though unsuccessfully worked out, the time and labor spent upon them cannot be said to have been wholly wasted. Indeed, we may consider, and be able to show later on, how a succeeding development may, by force of circumstances, revert to an original form long extinct or forgotten. But we must pass on to the time when we find the dynamo to be a *fait accompli*, and the reversibility of the dynamo a well-recognized effect.

With these powerful allies brought to its aid, and, we may add, its natural enemy, the primary battery, at last made harmless, the electric railway received another strong impulse of development, and arrived at what we may call the second stage in its evolution. Let us examine for a moment the elements as employed by the early workers in this field, and constituting what may be called the electric road of 10 years ago and up to, and including, that of recent date.

We have:

1. The generator.
2. The insulated conductor from generator to car.
3. The motor on the car.
4. The gearing from motor to axle.
5. The return circuit to the generator.

Let us take each element separately, and see what changes have been brought about from that period of 10 years ago up to the present. Taking up the generator first, it might be said that it would be difficult to trace any particular change which the influence of the electric railroad itself might have brought about. But even here, we can discern certain tendencies which may show themselves more markedly at a future period, and which seem to evolve in the direction of large multipolar dynamos of comparatively slower speed than the familiar two-pole machine generally employed at the present time.

But we pass on to our second element, the insulated conductor. Siemens, Daft, Edison and Field, and others started out with one rail, or an independent central rail insulated from the ground as their main conductor, connecting generator and car. The restrictions which such a mode of carrying the current obviously placed upon the operations of the road soon became apparent, however, and the step from a conductor placed upon the ground to one suspended above it was but a natural one. What do we find as the first attempts in this direction? The weight of the motor being no longer available as an additional means of insuring good contact between the conducting rail and the wheel bearing upon it, Siemens conceived the idea of employing the split tube, in which a slider acted as a contact device. The inconveniences of this arrangement however, also soon became apparent, and the plain cylindrical wire took its place, and has maintained its position up to the present time. The sliding contact inside the split tube was then converted into a trolley-wheel, which at first, and most naturally, was placed on top of the wire, riding upon and supported by it, the weight of the wheel insuring the integrity of the contact. But the trolley-wheel riding upon the wire was soon found to be accompanied by certain inconveniences, and the next step in this development was to place the trolley on the end of a pole and press it in contact with the wire from below, by which means not only is all strain removed from the wire, but the latter is actually supported during the passage of the wheel in contact with it. This development so briefly sketched here was, however, the result of innumerable experiments, and the various forms which the trolley-wheel has taken in the past would alone make an interesting chapter in a volume descriptive of this work.

While on the subject of conductors, also, we may turn aside to look at the state of the art as far as it includes placing the conductor below the surface of the earth. This was early suggested, but its development has been delayed; not, I am certain, from any inability to successfully settle the problem, but for reasons which you probably are all aware of, and which involve merely financial considerations.

We come now to the motor. Here we find a still larger field than we have heretofore met with, although, in general principles, of course, all the evolutions going on are alike. Starting out with the practice of employing but one motor to each car, time and circumstances seem to have dictated the use of two motors, which are generally in use at the present time, and the reasons for the adoption of which seemed eminently sufficient at the time the changes were made. Principal among these were the facts that by the employment of two machines power was transmitted directly to two axles independently, instead of to one, as theretofore; again, it admitted of smaller machines being employed which could find easier place under the car body; and, for the reason which was once broached, but which we believe the electric railroad has outlived, viz., that in case of the breakdown of one machine, it would allow of the car being brought home by the second for repairs. In connection with the motor, also, and intimately related to it is the method of regulation and the type of machine employed. Starting out with the employment of external resistances placed in the circuit for the purpose of regulating the speed of the motor and car, this differentiated in some quarters into a combination of the field windings of the motor to effect the same purpose, although the method originally adopted is still adhered to by some as being preferable.

---

[1] A paper read before the Boston Electric Club, April 14, 1890.

We must leave this point for the present, and pass on to the gearing by which the power of the motor is transmitted to the axle on which the wheels are mounted. While up to the present, the elements that we have been considering were practically new, and, therefore, amenable in the highest degree to the process of evolution, the gearing of the car at once gave a wide scope to the electric railway engineer, by placing at his disposal mechanical devices, many of which had been in current use for years and years in other work, and which his own ingenuity increased in number and changed to suit his own particular needs. As a result, we find that one of the first devices used for transmitting the power from the motor to the axle was by the well-known belt. Then came the friction gear, which, in turn, was followed by the chain and sprocket wheel, and this by the worm and wheel, the direct crank motion, until we arrive at the present most general form, the gear and pinion. Before this point had been reached, however, a multitude of devices, modifications of those above mentioned, were employed or suggested. Even in the method at present in use, what changes have we not seen, and what has not been tried to overcome some of the difficulties experienced, due to the wear and tear, etc., to which such gearing is subjected? I need only refer to the various materials which have been employed for the construction of the gears to make them durable and noiseless, among which, gun metal, raw hide and steel, and others have figured prominently. Unfortunately, thus far, where one material has been found good in one case, it has generally been found defective in another.

We would pass on, however, to the fifth and last element in the electric railway system, that is, the return circuit from motor to generator. The ground return which was the earliest form employed in the modern electric railway, may be well considered to be the prevailing one, for although the rail is brought into service, it is merely as an auxiliary; but, on the other hand, the metallic return is also employed to some extent, and, in some respects presents advantages which cannot be denied, and of which we shall have occasion to say more later on in discussing the probable development in this direction.

We have thus traced in rapid review the changes which the electric railway has undergone up to the present day, and having thus briefly sketched the process, as it were, by which this state of development has been reached, let us follow out the line of thought, and see if we can determine in what direction and in what manner further evolution will take place. Evolution as a rule tends constantly to the production of a higher type,—one which is better adapted than its predecessor to the surrounding conditions. The electric railway may, and I am sure it will, develop into a better and higher type. As Dr. Joseph Cook, of your own city would say, it will harmonize better with its environments. The employment of the word "better" naturally implies a certain inferiority in the present state of the art, and while no one is more impressed with the magnificent progress made during the past decade (progress against heavy odds, ignorance and conservatism, and the antagonism of vested rights or vested wrongs) it would be folly to say that the electric railway of to-day is perfect. Indeed, it would be against the laws of nature, and stamp the art as one incapable of improvement, than which no greater ill could befall it. Electric railroading being an eminently progressive art, therefore, let us see if we can discern in what direction evolution can be looked for. But, before going further I deem it proper to say here, that in what follows I do not wish to be considered as in any way criticising the electric railway system of to-day, for you and I know but too well that even in the present day it stands without a rival. I wish merely to hint at the direction in which still higher perfection may be reached, and this can best be done by taking up the elements in the order first named.

Taking up the generator, therefore, I think it will be conceded that it has even to-day reached such a standard of perfection that little may be expected in the future in the way of an increase in its efficiency, and the changes which do take place will be more in the direction of cheaper construction, and possibly, as the tendency seems to be largely to-day, towards reduction of speed.

But when we come to the conductor by which the motor is fed with the energy necessary for its propulsion, we encounter the element which is indeed one capable of some evolution, and when we use the word "conductor" we mean not only the wire but all those elements which are subsidiary to it, and which go to make up what we may call the conductor system as a whole. I use the word "evolution" advisedly, in contradistinction to the word "development," for while development in detail is naturally to be expected, the process of evolution which the electric railway is passing through at the present time may make entirely unnecessary the existence of such a system of conductors. I imagine that many of you have already divined what I am about to call attention to, and that is, the presence and the possible influence of the storage battery on the progress of electric locomotion.

Though storage batteries may be said to be in successful operation in a few instances at the present day, notwithstanding the difficulties which their employment presents, due, principally, to the large weight necessary for obtaining the required power, is it likely that the art of storage battery making will remain stationary, and that no improvements in that direction are to be hoped for? I certainly cannot bring myself to believe that such is the case; indeed, I am convinced that with the large number of workers in this field, the next five years will produce a battery which will be adapted to railroad work, not only by its construction and durability, but chiefly by its lightness compared with the power which it is able to develop. With such a battery in the field, applicable to the heaviest work, you can well see that the entire complexion of the electric railway situation will be changed, so far, at least, as the question of conductors is concerned.

But, given that the surmise just ventured should not be realized, will the present type of conductor be maintained in the future? The type most generally employed at the present time is the overhead single conductor, carried on a pole, or on span wires; while, on the other hand, the complete metallic circuit is also to some extent coming into use. Already we hear mutterings of complaint from certain quarters relative to the inductive effects caused by the arrangement with the single wire and ground return. Whether or not the change to metallic circuits will be made, will, I think, depend more upon the decision of the courts than on the relative merits of the two systems.

The question whether the conductors of the future in large cities will be placed underground, is, in a certain sense, problematical, in view of the fact before pointed out, that the near future may make the consideration of conductors out of the question by the employment of storage batteries as a secondary source of energy on a car. But again, on the assumption that storage batteries will not be forthcoming, the paths open in the consideration of underground construction lead in various directions. Will it be a pair of bare conductors from which current is taken and returned by means of brushes attached to a car and projected through a slot in the street? Or will it be one of those ingenious methods in which the conductor is insulated throughout, but connected at intervals with the track which it energizes locally at the spot which the car happens to be traversing at any instant? These are questions which it would be difficult to answer.

Still I think it is fair to assume that the overhead system will continue in use for a considerable period of time, even in the largest cities, and the evolution which may be looked for, is a thorough standardizing of all the details. It is not improbable either that the general type of overhead construction may be materially modified by the substitution of a light and graceful truss spanning the street in place of the span-wires now employed. There are undoubted advantages in such a construction, both as regards safety and economy of maintenance. Such a system might also to a considerable extent lessen the number of posts placed in the streets, as it would permit of longer spans than is deemed advisable at present. Again, the conductor system of the future will, I think, largely resolve itself into a system built up of small units or sections intimately connected and interlaced and supplied with independent feeders. Such a system is specially desirable in large cities, where interruptions on one part of the line due to street blocks, fires, processions, or even a break in the circuit, etc., may necessitate a detour of the cars and their massing on other sections of the line. Ample feeder capacity and small sections will thus make a general stoppage of traffic impossible. Unquestionably the place best adapted for the conductor, every thing considered, is overhead.

I must leave those problems to your consideration and, I hope, for your discussion later on to-night, and pass to the next two elements, which we will consider together, that is, the motor and the gearing which connects it with the axle.

Briefly recalled, the present practice may be said to consist in employing two motors, running at high speed, connected to the axles through gear and pinions, which on an average, effect a reduction in speed of 12 to 1. I think we can already discern more than one change which the near future will bring about in both these elements.

Taking up, first, the employment of two motors, I think it is not improbable that we shall find a reversion to the older type to be the next process in the evolution of the electric railway; that is, that one motor will probably in the future be employed to drive the car, connected to either one or two axles. Let us see the reason for this. Although two motors may be built by the same hands, it is a physical impossibility to build two alike. This means that such motors placed on a car and connected to the same switch, and, as a rule, connected in parallel, will act unequally, one taking more current than the other, and introducing irregularities in working which one motor alone would not produce. Again, the loss which takes place on starting the car from rest to motion is almost double, when two motors are employed, as compared with the case where but one is employed, owing to the fact that at the low starting speeds, the motor has not had time to obtain its maximum efficiency of action.

Again, it not infrequently occurs that the car in starting takes anywhere from 50 to 100 amperes of current through the two motors; but I believe that experiments have demonstrated that if one motor alone is employed, the draft of current at the starting would not be nearly as heavy as just indicated.

Again, looking towards the future of heavy city traffic the question also forces itself upon the mind whether accumulated experience may not prove that greater economy is to be obtained in the use of individual electric locomotives or motors, which shall draw a train of two or more cars, instead of the present method of providing each car practically with its own motive power equipment. Take for instance the condition of affairs in your own city. With the different styles of cars, box and open, only one style can be on the road at one time, and of the 2,000 cars probably one thousand are constantly idle. But each of these 1,000 must be fully equipped for work at a moment's notice. This means an enormous outlay practically unproductive of profit and requiring care for its proper maintenance. If individual motors were employed, only 500, say, would be required, to draw any style of car a number at a time, the cars being of the ordinary type without motor equipment. This is an important question which, I think, will soon command prominence, and which would be an apt example of reversion to a type practically extinct at the present day, though the first employed.

Passing on for a moment to the method of connection of the motor to the car axle, I believe that those persons who have had practical experience of electric railway operation will agree with me that evolution in the direction of electric car gearing will develop remarkable changes in a very short time. Notwithstanding the great ingenuity which has been exhibited in this department of car gearing, and the truck arrangement generally, certain inherent difficulties have developed themselves in this direction which, it is now well recognized, must be eliminated. Taking the gear as the working medium alone, the high speed at which electric motors are operated at the present time is proving very destructive, and from the gear and pinion, each made of cast-iron, we have passed successively through steel, bronze, and other composition mixtures, raw hide and steel and fibre. While each possessed its own particular advantage it was also accompanied by a disadvantage. Thus, for instance, the raw hide and steel pinion very soon developed a trouble, which consisted in the grooving of the meshing gear, which soon made its substitution by a new one absolutely necessary. In this direction alone much can be done, as I have already pointed out.

Again, as the high speeds employed in the motor are, in a great measure, responsible for these troubles, the remedy seems obvious, and is, I believe, already about to be applied in the employment of slower speed motors, and the reduction in the number of steps in the gearing from two pairs to a single pair; in other words, in the reduction of speed from 12 to 1, to something in the neighborhood of 5 to 1. This will probably involve the evolution from the 2-pole motor to a 4, or more, pole motor on the car.

Looking at the question from another standpoint, that of efficiency, or, to put it in plain language, that of the coal pile, I think another illustration of the present conditions can best be shown by alluding to the fact that the results of tests show that nearly 50 per cent. of the energy developed by the steam engine is lost in its various transmutations from the dynamo to the car axle. Placing the loss in the dynamo and in the line at 20 per cent., we have an additional 30 per cent. lost in the motor and the gearing. This excessive amount is one which, I believe, can be considerably reduced, and the remedies suggested have been various. In the first place, there can be no question that the present practice of stopping and starting the motor, by which enormous drafts of current are taken upon starting, can be overcome by a change in the electrical design of the motor and the switching arrangements. On the other hand, it has been suggested that the low efficiency at which the motor operates before it attains its normal speed, can be overcome by an arrangement in which the motor is constantly revolved at its most economical speed, independently of the movement of the car, by providing a suitable gearing by which the motion can be transmitted to the axle. It may be argued that this method may introduce other difficulties, especially in the gearing; but as a principle, pure and simple, it must be admitted to be an idea which is well worth consideration, and which may be developed to good advantage. The other fraction of the 30 per cent. lost between the engine and car axle, is evidently in the gearing itself. It is evident, of course, that every stage in the transmission must involve some loss, but the excessive amount which appears to be lost at present seems certainly capable of diminution. The change from the present high-speed motor, and its double reduction of speed through two pairs of gear with a slow-speed motor and a single pair of gears will, I think, effect a large gain in the direction just pointed out, and we shall probably soon be enabled to judge by experience of the practical value of this arrangement.

As regards the return circuit of the future, whether it shall be overhead, underground, or through the earth, depends largely upon circumstances. In view of the rapid spread of "æstheticism" in this country, notwithstanding the noble lead which your own city has taken on the question of overhead conductors, it seems doubtful whether in many large cities that type of construction can be maintained, and granted that it is, will the present type of construction be continued? It is probable that if it is, it will resolve itself into the system which is already gaining ground rapidly, in which the main feeders will be placed underground, and the working conductors placed upon poles through the centre of the street where double tracks are employed. These poles will not only be available for the suspension of electric railway conductors, but will also serve as supports for the arc and incandescent lights used in the illumination of the streets. As pointed out before, however, the question is one which, in view of the presence of the storage battery, is difficult to discuss, so far as its future aspect is concerned.

But finally, looking generally at the question of the future of electric railroading, and speculating as to its probable extension for traffic other than for street and suburban service, it is proper to consider whether the electric railway will eventually replace the steam engine for trunk lines. While such a change is, of course, by no means impossible, considered from every standpoint, it is probably one which will not come to pass for a long time, if for no other reason than the conservatism of the average railway man. But aside from this aspect of the case, an analysis will, I think, show that there are certain defined limits beyond which electric railroading may not compare with the direct steam locomotive. I have not made a sufficiently close study of this aspect of the case to give any actual figures, and I believe that we shall soon be afforded some definite information on the subject.

But there is still a field for the electric railway beyond mere city traffic, which will, I think, shortly develop into considerable proportions, and that is, in the operation of branch lines to the main steam railway lines, and as connecting links between them. There are many places where such lines, in many cases less than 50 miles in length, could be economically worked on the electric system, and that the advantages afforded are already recognized is evidenced by the fact that the idea is already being put in practice. As an example, I may mention the fact that at Sunbury, Pa., the connecting link between the Lehigh Valley and the Reading Railroads, is an electric railroad, which has contracted to be operated at a speed of 25 miles an hour, and which carries both freight and passengers between the two systems, including in its length the passage through a bridge a mile long. The motor of the electric car is of 30 h. p., and a single one is employed. The advantage of such feeders to main lines is still more apparent when we consider the large distances separating the main lines of railways in the far West, where frequently hundreds of miles intervene between parallel railway lines, and where electric roads might be reticulated..

The probable development of the electric railway might be followed out in a great many more directions, but I think enough has been said to prove that the changes which will take place will be extremely rapid, and that the electric car and the electric railway system generally, of ten years hence, will be quite unlike that of the present day.

I regret very much that the time at my disposal has been insufficient to present a more elaborate and better-digested treatment of the subject, and indeed, what has been said is intended more as the basis for a discussion of the subject, which I hope will be indulged in, than a thorough treatment of the same.

.... MANKIND fails at least a hundred times to one compared with the failure of a mechanical contrivance.—*Sir D. Salomons.*

.... WHEN an experimental fact was obtained by Faraday, it was instantly enlarged by his imagination.—*John Tyndall.*

.... THE public is still so ignorant on electrical matters, that some scheme should be set on foot to enlighten it.—*Sir D. Salomons.*

.... NOTHING looks so bad as a bundle of wires all twisted and hanging about loosely, and if there has been any slovenly wiring in a house, it will always be found in its most violent form at the indicator.—*F. C. Allsop.*

.... UNLESS electrical work be thoroughly well done and passed by competent persons other than the fire office inspectors, who have often not sufficient practice to understand every detail, the result will not be satisfactory.—*Sir D. Salomons.*

ELECTRICAL RADIATION FROM CONDUCTING SPHERES, AN ELECTRIC EYE, AND A SUGGESTION REGARDING VISION.[1]

BY OLIVER J. LODGE.

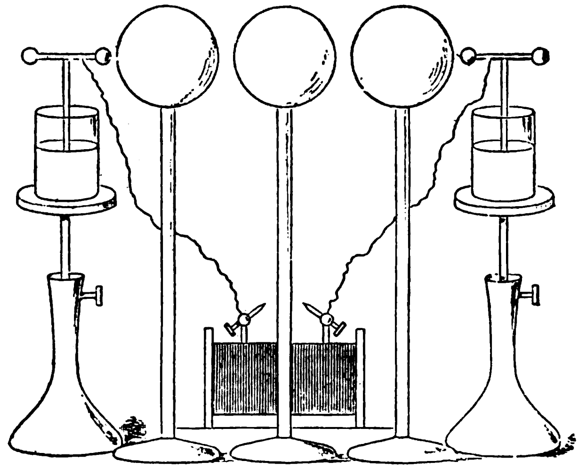
I do not know how far the description of little isolated experiments is serviceable, but I am tempted to communicate a simple plan I use for exciting electric oscillations in dumb-bells, ellipsoids, elliptical plates, spheres, or other conducting bodies of definite geometrical shape unhampered by a bisecting spark-gap. I do it by supplying electricity to opposite ends of the conductor by means of Leyden jar knobs brought near enough to spark to it; said knobs being likewise connected with the terminals of a small Ruhmkorff coil. The charge thus supplied or withdrawn at every spark settles down in the conductor after a few oscillations, and these excite radiation in surrounding space.

There are many ways of arranging the Leyden jars, some more effective than others. The outer coats of the two jars may, or may not, be connected together. Connecting them in some cases brightens the sparks at short range, but seems to have a tendency to weaken them at long ranges. It is not difficult to surmise why this is so.

Of course, when the outer coats are disconnected, only an insignificant portion of the capacity of the jars is utilized; but unless the thing to be charged has too large a capacity it works perfectly well.

The receiver or detector is a precisely similar conductor touched to earth by a point held in the hand. The distance at which such a receiver responds is surprising. Or one may use a pair of similar conductors and let them spark into each other; but this plan is hardly so sensitive, and is more trouble.

The fact of being able in actual practice to get radiation from a sphere, is interesting, inasmuch as the subject of electrical oscillations in a perfectly conducting sphere has been worked out accurately by Professor J. J. Thomson in the London Mathematical Society's Proceedings. I have not the volume by me, but I think he reckons the period of oscillation as the time required by light to travel 1.41 diameters of the sphere.



Experiments in Electric Radiation.

The case of spheres of ordinary metal will not be essentially different, with these rapid oscillations, for the electric currents keep to a mere shell of surface in either case; and in so far as *damping* affects the period, the dissipation of energy by radiation (which is common to both) is far greater than that caused by generation of heat in the skin of a metal sphere.

I happened to have four similar spheres of nickel-plated metal on tall insulating stems; each sphere 12.1 centimetres in diameter. Applying spark knobs to each end of a diameter of one of them, and applying the point of a penknife to another one standing on the same table at a distance of two and a half metres, I am able to get little sparks from it without using any reflector or intensifier.

Or arranging three spheres in a row, with intervals between and knobs outside, 5 short spark-gaps in all (see figure), and using a fourth sphere as a detector of this triple-sourced radiation, I draw little sparks from it to a touching penknife at a distance of 12 feet (366 centimetres, actual measurement.)

In this case it may be a trifle better to hold one's hand near the receiving sphere at the side opposite to the penknife, and thus vary its capacity by trial so as to imitate the disturbing effect of the contiguous spheres in the transmitter.

The complete waves thus experimented on and detected are only 17 centimetres (six and a half inches) long, and I imagine are about the shortest yet dealt with.

But we do not seem near the limit set by lack of absolute suddenness in sparks yet, and are going on to try a large number of little globes.

Exciting a lot of little spheres by a coil in this way forcibly recalls to mind the excitation of a phosphorescent substance by a coil discharge.

And a receiver not very unlike the rod-and-cone structure of the retina can likewise be made. My assistant has been experimenting on a sort of gradated receiver which he made himself. I have recently had made a series of long cylinders with diameters ranging above and below 12 centims.; and the length of each which responds to radiation is a kind of measure of specific intensity. They form (speaking sensationally) an electric eye with a definite range of color sensation. It would be easy to supply it with a pitch or paraffin lens.

There is no need to suppose the retinal bodies to be conducting; a body of high refractive index should be subject to electric vibrations, and its surface to spurious electrifications, when radiation falls upon it; and the optical density of the rods and cones is known to be high. They may, however, be electrolytic conductors; and I find that a liquid sphere—*e. g.* a flask of inky water—responds to radiation, giving a glow to a point touching its glass.

The diameters of the rods, as measured by various physiologists, are not very different from dimensions adapted to respond to actual light-vibration frequency; and if this idea substantiates itself, these bodies can be supposed to constitute a sort of Corti's organ responding to etherial instead of to aërial vibrations, and stimulating in some still unknown, but possibly mechanical, manner, the nerve-fibre and ganglion with which each appears to be associated.

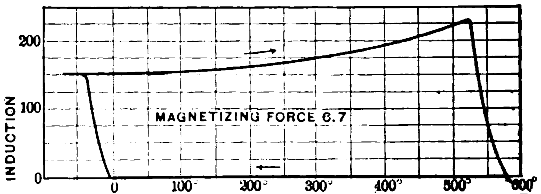
MAGNETISM.

BY DR. JOHN HOPKINSON, F.R.S.

(Continued from p. 248.)

The properties of an alloy of manganese and iron are curious. More curious are those of an alloy of nickel and iron. The alloy of nickel and iron containing 25 per cent. of nickel is non-magnetic as it is sure to come from the manufacturer; that is to say, a substance compounded of two magnetic bodies is non-magnetic. Cool it, however, a little below freezing, and its properties change: it becomes very decidedly magnetic. This is perhaps not so very remarkable; the nickel steel has a low critical temperature—lower than we have observed in any other magnetizable body. But if now the cooled material be allowed to return to the ordinary temperature it is magnetic; if it be heated it is still magnetic, and remains magnetic until a temperature of 580° C. is attained, when it very rapidly becomes non-magnetic, exactly as other magnetic bodies do when they pass their critical temperature. Now cool the alloy: it is non-magnetic, and remains non-magnetic till the temperature has fallen to below freezing. The history of the material is shown in Fig. 11, from which it will be seen that from —20° C. to 580 C. this alloy may exist in either of two states, both quite stable—a magnetic and a non-magnetic—and that the state is determined by whether the alloy has been cooled to —20° C. or heated to 580° C.

Sudden changes occur in other properties of iron at this very critical temperature at which its magnetism disappears. For example, take its electrical resistance. On the curve Fig. 12 is shown the electrical resistance of iron at various temperatures, and also the electrical resistance of copper or other pure metal. Observe the difference. If the iron is heated, its resistance increases with an accelerating velocity, until, when near the critical temperature, the rate of increase is five times as much as the copper; at the critical temperature the rate suddenly changes, and it assumes a value which, as far as experiments have gone, cannot be said to differ very materially from a pure metal. The resistance of manganese steel shows no such change; its temperature coefficient constantly has the value of .0012, which it has at the ordinary temperature of the air. The electrical resistance of nickel varies with temperature in an exactly similar manner. Again, Professor Tait has shown that the thermo-electric properties of iron are very anomalous—that there is a sudden change at



Elect. Engineer, N.Y.

Fig. 11.

---

[1] *Nature.*

or about the temperature at which the metal becomes non-magnetic, and that before this temperature is reached the variations of thermo-electric property are quite different from a non-magnetic metal.

Professor Tomlinson has investigated how many other properties of iron depend upon the temperature. But the most significant phenomenon is that indicated by the property of recalescence. Professor Barrett, of Dublin, observed that if a wire of hard steel is heated to a very bright redness, and is then allowed to cool, the wire will cool down till it hardly emits any light at all, and that then it suddenly glows out quite bright again, and afterwards finally cools. This phenomenon is observed with great difficulty in the case of soft iron, and is not observed at all in the case of manganese steel. A fairly approximate numerical measurement may be made in this way: Take a block of iron or steel on which a groove is cut, and in this groove wind a coil of copper wire insulated with asbestos; cover the coil with many layers of asbestos; and finally cover the whole lump of iron or steel with asbestos again. We have now a body which will heat and cool comparatively slowly, and which will lose its heat at a rate very approximately proportional to the difference of temperature between it and the surrounding air. Heat the block to a bright redness, and take it out of the fire and observe the resistance of the copper coil as the temperature falls, due to the cooling of the block. Plot a curve in which the abscissæ are the times, and the ordinates the logarithms, of the increase of resistance of the copper coil above its resistance at the temperature of the room. If the specific heat of the iron were constant, this curve would be a straight line; if at any particular temperature latent heat were liberated, the curve would be horizontal so long as the heat was being liberated. If now a block be made of maganese steel, it is found that the curve is very nearly a straight line, showing that there is no liberation of latent heat at any temperature. If it is made of nickel steel with 25 per cent. of nickel, in its non-magnetic state the result is the same—no sign of liberation of heat. If now the block be made of hard steel, the temperature diminishes at first; then the curve, Fig. 13, which represents the temperature, bends round; the temperature actually rises many degrees whilst the body is losing heat. The liberation of heat being completed, the curve finally descends as a straight line. From inspection of this curve, it is apparent why hard steel exhibits a sudden accession of brightness as it yields up its heat. In the case of soft iron the temperature does not actually rise as the body loses heat, but the curve remains horizontal or nearly horizontal, for a considerable time. This, again, shows why, although a considerable amount of heat is liberated at a temperature corresponding to the horizontal part of the curve, no marked recalescence can be obtained. From curves such as these it is easy to calculate the amount of heat which becomes latent. As the iron passes the critical point it is found to be about 200 times as much heat as is required to raise the temperature of the iron one degree centigrade. From this we get a very good idea of the importance of the phenomenon. When ice is melted and becomes water, the heat absorbed is 80 times the heat required to raise the temperature of the water one degree centigrade, and 160 time the heat required to raise the temperature of the ice by the same amount. The temperature of recalescence has been abundantly identified with the critical temperature of magnetism.[1] I am not aware that anything corresponding with recalescence has been observed in the case of nickel. Experiments have been tried, and gave a negative result; but the sample was impure; and the result may, I think, be distrusted as an indication of what it would be in the case of pure nickel. The most probable explanation in the case of iron, at all events, appears to be that when iron passes from the magnetic to the non-magnetic state, it experiences a change of state of comparable importance with the change from the solid to the liquid state, and that a large quantity of heat is absorbed in the change. There is, then, no need to suppose chemical change; the great physical fact accompanying the absorption of heat is the disappearance of the capacity for magnetism.

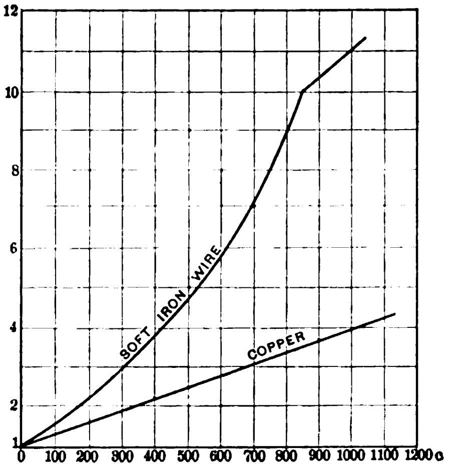


FIG. 12.

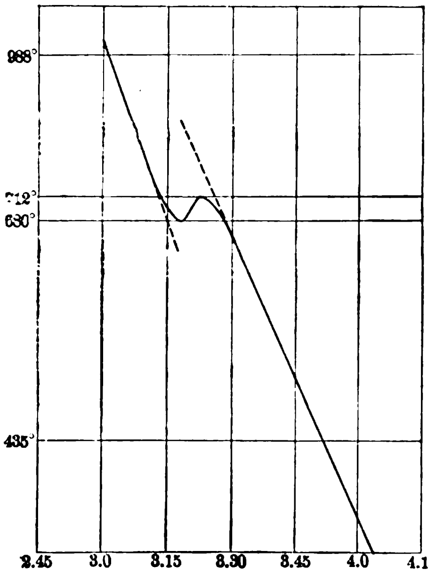

FIG. 13.

(*To be concluded.*)

THE ELECTRICAL SECTION OF THE CENSUS.

PROGRESS OF THE WORK.

THE following schedules have been completed, and a copy is now ready for the printer:

LIST OF SCHEDULES.

1. Manufacturers of electrical apparatus, instruments and supplies.
2. Electric light and power central stations.
3. Fires caused by electric currents. Information to be obtained from electric central station companies.
4. Fatal casualities occuring on electric currents. Information to be obtained from electric central station companies.
5. Fires caused by electric currents. Special investigation in cities of 10,000 population and over.
6. Fatal casualties occuring on electric currents. Special investigation in cities of 10,000 population and over.
7. Isolated electric lighting and power plants.
8. Educational institutions. Electrical engineering courses.

The schedule for central station companies required infinitely more work for its preparation than any other. While in preparation it was shown to a large number of managers of central station companies and others, and full benefit has been taken of every suggestion offered. Every possible effort has been made to render it full, plain, complete and practical. The range of inquiries in the complete schedule necessarily covers all apparatus and service that a central station company may have in use or render.

THE ELECTRICAL SUB-DIVISIONS OF THE SCHEDULE.

1. Underground conduits.
2. Underground conductors.
3. Aerial conductors.
4. Incandescent lamps.
5. Arc lamps.
6. Converters.
7. Accumulators.
8. Meters.
9. Stationary motors.
10. Current supplied to motor cars.

---

[1] I have only recently become acquainted with the admirable work of M. Osmond on recalescence. He has examined a great variety of samples of steel, and determined the temperatures at which they give off an exceptional amount of heat. Some of his results are apparent on my own curves, though I had assumed them to be mere errors of observation. For example, referring to my Royal Society Paper, there is, in Fig. 38, a hint of a second small anomalous point a little below the larger one. And comparing Figs. 38 and 38*a* we see that the higher the heating the lower is the point of recalescence; both features are brought out by M. Osmond. The double recalescence observed by M. Osmond in steel with a moderate quantity of carbon, I would explain provisionally by supposing this steel to be a mixture of two kinds which have different critical temperatures. Although M. Osmond's method is admirable for determining the temperature of recalescence, and whether it is a single point or multiple, it is not adapted to determine the quantity of heat liberated, as the small sample used is enclosed in a tube of considerable mass, which cools down at the same time as the sample experimented upon.

To avoid sending a company inquiries that do not pertain to its business, the schedule will be printed in sections. To ascertain what section to send to each company, the following inquiries are being sent out to be answered at once.

1. Do you own or operate underground conduits?
2. Do you operate incandescent lamps?
3. Do you operate arc lamps?
4. Do you operate a converter system?
5. Do you operate an accumulator system?
6. Do you operate stationary electric motors?
7. Do you operate or supply current to electric motor cars?
8. Are you making, or do you contemplate making additions to your plant during the year 1890? If so, please state of what the additions will consist, and give the total amount of estimated cost.

The last question is intended to make "the pigs stand still until they can be counted."

The returns from the preliminary schedules sent out in February and March are quite satisfactory. An official directory of electric central station companies is now being compiled from these schedules, and all other sources of information at command. If any company has failed to return the preliminary schedule, it will oblige the Census Office greatly by doing so at once. In case a company has failed to receive this schedule, one will be forwarded at once if it will kindly give notice of the fact. All companies are earnestly requested to notice carefully the way their names are written on all papers addressed to them, and to make needed corrections in their replies. With such assistance, and due diligence in the Office, a creditable degree of correctness may be attained.

The schedules that have been prepared outline only a portion of the work. To sub-divide the inquiries for Manufacturers, directories are being compiled, classified as follows:

DIRECTORIES OF MANUFACTURERS.

1. Dynamos.
2. Motors.
3. Incandescent lamps.
4. Arc lamps.
5. Carbons.
6. Insulated conductors for electric currents.
7. Conduits.
8. Primary cells.
9. Accumulator cells.
10. Electric meters.
11. Electric clocks.
12. Electric welding apparatus.
13. Electro-plating machines.
14. Electric fire alarms.
15. Electric burglar alarms.
16. Electrical apparatus for use in medicine and surgery.
17. Electrical instruments.

Extended as this list is, it requires many additions to make it complete.

A letter has been addressed to each manufacturer, requesting him to assist in furnishing information for a chapter in the Census report, on the "Manufacture and Uses" of the special apparatus named. This letter solicits:—

1st, A list of all manufacturers of the apparatus.

2d, A list of the addresses of all users of the apparatus when this is practicable, together with a statement of the purposes for which it is being used.

3d, A full description of any novel or special use being made of the apparatus.

4th, Suggestions of pertinent inquiries for a schedule to be sent to manufacturers and also for a schedule to be sent to users of the apparatus when desirable, for the purpose of obtaining information considered to be important.

It is very clear that this invitation affords manufacturers an opportunity to furnish information, the publication of which will be a revelation, not to laymen alone, but to those most familiar with the progress being made in adapting electrical energy to the services of civilized life. Such a publication will vastly increase popular knowledge and appreciation of the advantages and value to be derived from the manifold uses of electricity. It will furnish a solid basis of facts for all arguments. Its impersonal and impartial character will convince the public of its truth. It will set at rest all doubts and fears. Future public action guided by it and dealing with electrical interests will be intelligent and consistent with the people's welfare. A truthful statement showing what electricity is doing, as it will be told in these chapters and others to be formed, will be enormously valuable to the people of this country.

The day is not distant when the economic value of applied electricity will be known to exceed that of the output of all mines of gold and silver; its administrations to health, to be more potent than all other remedies; and when all peoples will be made neighbors and friends by its matchless power to convey intelligence and persons. When that day comes, he who attempts to cast odium upon any form of the apparatus through which electricity manifests its helpful power, or seeks to block its progresssive development by raising false danger signals, will be known and shunned as an enemy to public welfare.

ALLEN R. FOOTE, *Special Agent.*

A NEW ARMINGTON & SIMS TRIPLE EXPANSION ENGINE.

FOUR years ago the Washburn & Moen Manufacturing Co., of Worcester, Mass., contemplated a radical change in their method of drawing steel wire, and proposed the adoption of a triple compound high-speed engine, that should, in fact, be three distinct centre-crank coupled, parallel engines with cranks at 120 degrees. By so locating the cranks, a dead centre was prevented and the engine could be started at any time, as provision was made to admit live steam, simultaneously, to each of three cylinders, so that if the crank of the high-pressure cylinder was on the dead centre, one of the others, and possibly two, would be effective. After starting, steam from the low pressure cylinders was shut off allowing the engine to run as designed and intended.

The amount of power desired was 700 h. p., and with three crank pins, whose relative positions were equally distant upon the circumference of a circle described by their centres, it was evident that the retardation of the crank pin of a long stroke slow-speed engine would be impossible in this case, as absolute uniform speed would have to be obtained. The requirements of such an engine would be very severe indeed, as the train of rolls would be directly connected by a rigid coupling to the shaft of the engine. Its load under 120 pounds pressure would at times be only the amount of power required to overcome the friction of the engine and rolls. Instantly it would be 700 h. p., as the steel bloom entered the first pair of rolls, and, after leaving, the automatic cut-off would control the speed with a variation of two per cent.

An offer to build this compound engine was made to the Armington & Sims Engine Co., Providence, R. I., but they being pressed with orders, kindly permitted the use of all of their inventions, together with models and drawings, for a nominal royalty, the engines being built elsewhere.

The Washburn & Moen Manufacturing Co. are pushing another new mill rapidly towards completion and have placed their order with the Armington & Sims Engine Co. for a compound engine of 1,000 h. p., to run from 200 to 250 revolutions per minute, having a piston speed of from 800 to 1,000 feet. Although 1,000 h. p. will be taken from one end of the shaft of this engine, the arrangement is such that 500 h. p. can be taken from each end. The automatic regulator is simple, easy of access, and entirely independent of the engine shafts, which are duplicates of each other. The same may be said of all of the parts of these engines which are interchangeable. The weight of the engines without pulleys or foundation boxes is 180,000 pounds.

The Ferranti electric light station at Deptford, London, has engines of 1,250 h. p. Their height above the floor is 43 feet, while that of the Washburn & Moen Manufacturing Co. is but five feet; length, 17½ feet; width, 16⅛ feet; or about 0.28 square foot of floor surface for 1-h. p. In large cities where real estate is very valuable and is an important consideration to the shareholder, it would be well for electric light and power interests, to think seriously of advancing another step which seems practical, in the direction thus indicated above.

Messrs. Armington & Sims have also in hand several special engines directly connected to dynamos, for foreign governments as well as our own navy department, and merchant marine. The dynamos are furnished by the Thomson-Houston, Edison, Brush and Wenstrom companies. This is but a return to the original plan of Mr. Edison with his first "Jumbo" dynamo and the Armington & Sims engine that was sent to the Paris Electrical Exhibition, in July, 1881. This combination is still doing good daily service. It should some day be brought back to this country and placed in the National Museum at Washington, as it was the first successful combination ever constructed, and should be preserved. Students will readily realize the progress and development of engines and dynamos during the past 10 years, and this, the latest departure, is well worthy of attention. If we are not mistaken, there is already a marked tendency in the direction indicated, so that with the larger engines we shall see slower speed dynamos of the multipolar type.

THE SALOMONS ELECTRICAL ENGINEERING SCHOLARSHIP.

Sir David Salomons has offered to devote £1,000 ($5,000) to the foundation of an electrical engineering scholarship. This will furnish a scholarship of £30 or £40 ($150 or $200) a year. The management of the matter is left in the hands of a committee of the Council of the Institution of Electrical Engineers.

.... THERE is one point connected with gas engines which most people overlook, and it is a very important one—the fuel is carried to the spot free of expense and without trouble at all times and in all weathers.—*Sir D. Salomons.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Lenox Lyceum Electrical Exhibition.—Lecture by Dr. S. S. Wheeler.—The Electrical Execution Chair.—Investigating Electric Traction and Gas Leaks.—Electric Traction Developments.—A Reception at the Brooklyn Edison Station.—City Electric Lighting Contracts.

THE management of the Electrical Exhibition in aid of the New York Exchange for Women's Work has devised a new feature for the show at the Lenox Lyceum. It is called "A Glimpse of the Twentieth Century," and is a comedy suggested by Bellamy's "Looking Backward." There are but two characters in the play, one of whom is a person who wakes in 1999 after a sleep of 104 years. He is then confronted with a twentieth century gentleman, and they converse together on the wonderful strides of arts and sciences that have been made during the century. The fun is confined to local hits, some of which are very good. Electrical effects are introduced. It may be mentioned that Mr. George H. Guy, the energetic secretary of the New York Electrical Society, who has provided so many pleasant and profitable meetings this season, has arranged for a special evening, on Friday, April 25, when tickets will be issued at half price to members of the Society, or of the New York Electric Club and the American Institute of Electrical Engineers. As ladies are particularly invited on this occasion, the attendance will doubtless be very large. Mr. Guy's address is 127 Temple Court, this city.

Last Friday, April 18, Dr. S. S. Wheeler delivered a lecture before the Y. M. C. A. in Harlem on the "Practical Uses of Electricity." The lecture was illustrated by experiments, and wires were run into the building for the occasion. The lecture brought a large audience together, and was greatly enjoyed.

The New York papers are agog about the execution of Kemmler next week. With regard to the "chair of death," a *Herald* reporter says: "It is not the clumsy piece of furniture, as you can plainly see, designed by that alleged electrical expert and newsmonger on the sly, Mr. Harold P. Brown. That piece of barbarity, with its helmet of fire and its glass footrests for naked feet, will go into innocuous desuetude before this simple and scientific contrivance, which, if electricity can be made merciful, ought to make it so. It will at least not torture the condemned man before it kills him. The latest form of chair—I cannot learn the name of the inventor, but I half suspect the Warden has had much to do with constructing it—is a comfortable chair with an upright back, and arms that are adjustable to those of the man that sits in it. There is a leather covered pillow for the head to rest against. Fastened to the back is an adjustable figure 4 which can be raised or lowered so as to come down over the head of the condemned. The technique of the thing is very simple. Through the lower outer angle of the 4 there is a hole, and through this will pass a rubber tube containing a rod of steel or copper, to which a wet sponge is fastened. This sponge will touch the crown of the condemned man's head. Another pipe, with webbing inside and a sponge, will pass up through the seat so as to touch the base of the spine, when the man is strapped firmly in his seat. This will be accomplished by the use of several straps, one passing around the chest, another around the abdomen, which will draw the webbing against the spine, while the arms will be firmly strapped to those of the chair on which they will rest. The feet will rest on a comfortable foot-rest, after the fashion of those in use in a barber shop. The current will be generated by a dynamo which has been placed near to the power room, a thousand feet away from the place of execution, and the insulated wires which will connect it with the rods and sponges have all been strung in readiness for their work."

The Senate Committee, now in this city investigating electrical matters have taken a glance at electric traction, and last week had Frank J. Sprague before them. They were treated to a clear, incisive sparkling talk, such as only Mr. Sprague can give, and will not now be able to say that they are not well and authoritatively informed on the subject. They also had before them Stephen McCormick, the Superintendent of the Bureau of Lamps and Gas in the Department of Public Works, who said that he had studied the subject of gas leakage for 14 years. When the gas mains were first laid they had been properly constructed, but Mr. McCormick thought that they had been weakened by the excavations that had been made all around them. The construction of subways was accountable for some of the leakage, as in many places the workmen had laid bare the pipes and had been careless in working around them. The average leakage of gas in this city was about 10 per cent., and no city authority had any control over the gas companies. All that the Department of Public Works could do in case of leakage was to inform the gas companies. As a rule, these companies were anxious to repair all leaks, but Mr. McCormick thought that the Commissioner of Public Works should have the authority to control them. In some of the avenues in New York there are six different gas mains, and on Manhattan Island there are 1,423 miles of gas mains owned by seven different companies. As to the pipes, Mr. McCormick said that those of wrought-iron made better joints, but they would not last as long as cast-iron pipes. Now that the electric wires were being put under ground, the question of gas leakage was becoming a serious one. Many deaths from gas in private houses, Mr. McCormick thought, were due to the lack of stops on the gas cocks, and inspectors of the Board of Health should look after these matters.

The reports as to the entry of the Westinghouse company into the electric railway field have excited general interest, especially as they are now confirmed. Another item in the same line is the report of an understanding arrived at between some of the other "independent" electric traction companies, from which interesting developments may soon be expected. The magnitude of the work to be done in this department is evidently attracting the attention of capital.

The Edison station in Brooklyn, which has already been described in THE ELECTRICAL ENGINEER, was the scene of a reception on April 8 and 10, when a large number of visitors inspected the arrangements and details of the handsome plant, as well as the Bergmann Co.'s showroom, the Perret motors running the workshop, the Sprague electric swing hoist, the new Ward, Kinsman and Universal arc lamps, and other special features. At the close of the reception on April 8, Mr. Edison, Mr. Hastings and others spent an hour at the Hamilton Club, in social enjoyment with its members, who valued highly this opportunity of meeting Mr. Edison face to face.

With regard to the city contracts for electric lighting, the *Sun* quotes Mr. Paul D. Cravath, as follows:—"Representatives of the electric light companies whose bids for lighting the city the Gas Commission considered so high that it refused to accept them, were unanimous yesterday in declaring that their various corporations would not have made anything if the bids had been accepted. They were also unanimous in saying that the cost of electric lighting in New York, even at the advance of four cents a lamp a night, would be less than in any other large city. The views of all are expressed with particular emphasis by Paul D. Cravath, counsel for the United States Illuminating Co. and the Brush Electric Illuminating Co., which together supply about 600 of the 1,000 lights used by the city. Mr. Cravath said that the price of 35 cents a lamp a night was originally agreed to by the different companies because, on account of the smallness of the appropriation, the city couldn't pay any more. The use of the subways, however, caused increased expenditure, so the United States and Brush had to raise their rates this year to an average of about 40 cents a lamp, the other companies doing the same. Nevertheless, continued Mr. Cravath, there was not a single company which would come out whole on the city lighting if the contracts were awarded to them at the prices named in the bids, and the companies would, if anything, be the gainers if the city give up the use of electric lights and returned to the use of gas, as it apparently proposes to do. At the prices named in the recent bids New York would be furnished with electric lights at much cheaper rates than in any other large city. According to Mr. Cravath, the price in Philadelphia is more than 50 cents a lamp a night, in Boston 55, in Brooklyn 50, in Washington 60 cents. In conclusion Mr. Cravath denied that there was any combination between the companies."

NEW YORK, April 18, 1890.

PHILADELPHIA.

Complaints of Telephone Service.—Western Union and the Telephone Conduits.—The Cope Underground Wiring System.—New Underground Lighting Service.

IN view of the many complaints made of poor service furnished by the Bell Telephone Co., the directors of the company held a meeting a few days ago, and authorized rebates for such time as 'phones are out of order. Dr. Plush, Superintendent of the local telephone company, said that the company would be glad to have all the business exchanges of the city appoint a careful conference committee to compare the telephone service in Philadelphia with that in other cities. He added that it would be an interminable work to introduce in this city the metallic circuit system.

The Electrical Committee of Councils has reported a bill to permit the Western Union Telegraph Co. to make connections with the underground conduits of the Bell Telephone Co. The Western Union company wanted to carry its wires from Third and Chestnut streets to Fifth and Market, and as Councils refused to grant the necessary authority the company appealed to the United States District Court, asking for an injunction to restrain the city authorities from interfering with the erection of its poles on the streets named. The Electrical Committee of Councils held an executive session last week, which was attended by City Solicitor Warwick, to consider the dispute. Mr. Warwick recommended the passage of an ordinance granting the Western Union company authority to connect with the conduits of the Bell Telephone Co. He intimated that if this ordinance should be passed the city would be in a position to successfully oppose the averment of the Western Union company, and this would, perhaps, save the Court from rendering a decision against the city. Chairman Graham, of the Electrical Committee, secured the signatures of thirteen members to the report. The matter will come up at the next meeting of Councils.

A number of persons interested in electric light, telephone and telegraph companies recently witnessed a test of a new method of running electric cables through underground conduits. The idea is based upon the principle employed in the pneumatic package and message delivery system. The plan now in general use is to have a number of small tubes that may be screwed together and by attaching these one to another as they are forced through the conduit a continuous tube is formed, and with the conductor fastened to the end of this it is drawn through, small sections at a time. This method is very laborious, and it is said requires two hours to run a cable through a square of street. The Cope system, which employs the pneumatic contrivance, shot a conductor through the Bell telephone conduit on Market street, between Second and Third streets, a distance of about four hundred feet, in three minutes. The cable was attached to a plug and was run off from a reel, inclosed in an air-tight case, and through a section of pipe connected with an air-pressure pump. The operation of the pump forced the plug through to the next man-hole at the end of the square and the attached cable, of course, went with it.

Councils Electrical Committee decided to report favorably an ordinance permitting the Columbia Electric Light Co. to lay and maintain underground conduits, cables and wires for incandescent electric lighting on Columbia avenue, from Broad to Twenty-third street; west side of Broad, from Columbia avenue to Master street; Fifteenth street, Sixteenth, Seventeenth, Eighteenth, Nineteenth and Twentieth streets, from Montgomery avenue to Master street.

PHILADELPHIA, April 18, 1890.

ST. LOUIS.

Electric Railway Work.—The Union Depot Railroad Power House.

SEVEN electric railroad bills have been signed by the mayor. The list includes the Benton-Bellefountaine, the Forest Park, Laclede and Fourth street, the Lindell, the Mound City, the Missouri, the Union Depot and the Vandeventer Avenue Railroad Co., a new cross-town road, which will be used as a feeder for the Lindell and the Missouri companies. The mayor also signed the St. Louis Railroad bill, which authorizes cabling of the main line and the use of storage batteries or overhead wire on the Seventh street section. A contract for 7⅓ miles of double track cable was closed yesterday, so this puts a quietus on electric power for the main line, as was conjectured last week.

The ordinances of the Forest Park, Laclede and Fourth street, the Missouri and the Lindell authorize the use of storage batteries or overhead wires. The Benton-Bellefountaine, the Mound City and the Union Depot are authorized to use overhead wires only while the new Vandeventer Avenue road is authorized to use overhead wires or cables. Speed is regulated to 10 miles per hour in the down-town district, and 12 and 15 miles per hour outside of this district. The Missouri and the Forest Park, Laclede and Fourth street companies are anthorized to extend their tracks into Forest Park and to erect jointly a $25,000 passenger depot.

The Lindell Railway Co. have let a contract to Rhoan Bros., of this city, for boilers of about 1,600 h. p. capacity, to cost some $24,000. A contract for Armington & Sims compound engines and a $25,000 passenger depot in Forest Park has also been closed.

The Union Depot Railroad power house car sheds and electrical equipment are approaching completion. A trial run was made last Saturday. The installation consists of three Heine patent safety boilers of 150 h. p. each, and two Hamilton-Corliss engines of 325 and 230 h. p. respectively. The countershafting, 96 feet long and 8 inches in diameter, fitted with Hill patent clutches, was furnished by the Eclipse Wind Engine Co., of Beloit, Wis. Rope transmission is used in transmitting power from the countershaft to dynamos. At present six of the latest improved 80 h. p. Thomson-Houston generators are in position, and two more will be added shortly. The wiring and switch-board fitting was carried out by Mr. Edward Verstraete, electrician. The switch-board, 16 x 12, of solid cherry, was built by the St. Louis Car Co., after special designs by Mr. Verstraete, is an elegant piece of workmanship, both electrical and mechanical, and a credit to both parties. Six motor cars are now on hand, and others will be fitted as fast as the car company can supply the cars, until the entire number—30—are fitted up. Reconstruction and wiring of track and the erection of overhead wires in the down-town district will be pushed to completion with all possible haste.

The stockholders of the Southern Railway Co. will hold a meeting May 5 for the purpose of voting upon a proposition to increase the capital stock from $200,000 to $500,000, and to authorize an increase of the bonded indebtedness to $500,000, the object of which is to change to electric power by overhead wire. Plans of their poles and overhead structure have been submitted to the Board of Public Improvements.

ST. LOUIS, April 18, 1890.

BOSTON.

The New Telephone Exchange.—The New England Electric Exchange. Thomson-Houston Annual Meeting.—New Offices of the Boston Fire Underwriters' Union.—Long Distance Telephoning.—Extension of Welding Applications.—Control of Electric Wires.—The Speed of Electric Railway Cars.—Meetings of the Electric Club.

THE new Telephone Exchange building, now in course of construction on State street, Boston, is to be fitted throughout with a complete system of incandescent electric lighting. This is one of the largest office buildings in the country, and the occupants will depend entirely upon electric light for artificial illumination, as no gas is to be introduced into the building. The contract for the wiring and appurtenances has recently been awarded to the New England Wiring and Construction Co., of Boston, the oldest house in this line of business in New England. The Interior Conduit system will be used throughout for the wiring, and all the latest and best methods in this class of work will be pursued in this building. Many features new to incandescent wiring will be introduced, and it is the intention to make this one of the most complete plants in the country. This is the largest contract for work of this character which has been awarded in New England, and the largest, with two or three exceptions, in the country. The building will be wired for about 5,000 16 c. p. lamps.

The annual meeting of the New England Electric Exchange was held in the rooms of the Boston Electric Club on Monday, when the annual report of the treasurer was read and accepted, and new officers for the ensuing year elected. Mr. P. H. Alexander, the retiring president, occupied the chair, and in his annual address he traced the growth of the Exchange from its birth two years ago, and alluded to the good work it had done. As the treasurer's report shows, the financial success of the enterprise is complete. When the Exchange started business the insurance and electrical interests were antagonistic. Now they are working in the greatest harmony, and as a proof of that, he said that the insurance companies were entertaining the idea of discontinuing inspections of electric light plants, owing to the greater confidence they have in the good quality of the work done. Mr. H. B. Cram, then read the treasurer's report, and afterwards gave the following license statement:

LICENSE STATEMENT. APRIL 14, 1890.

Class.	Applied.	Granted.	Rejected.	Examined but not reported.	Not examined.

Licenses renewed for one year	64	67

Licenses expired 78
Of which .... 2 have applied for renewal and the
76 applications are awaiting action.

Of the 76 licenses which have expired: 7 applied a second time and have licenses now in force; 1 applied a third time and has license now in force; 2 applied a second time and the second licenses have expired; 1 applied the second time and the second license has been extended.

The following gentleman were then elected as officers for the following year: Mr. Alex. P. Wright, president; Mr. H. H. Fairbanks, secretary and treasurer, and Messrs. W. S. Hill, E. H. Hewins, and H. C. Spaulding, directors. Mr. S. E. Barton, then paid a high tribute to the past good work of the Exchange, and drew attention to the fact that, according to the secretary's statement, there was a licensed man for each electric light station in New England. Mr. E. C. North, the newly appointed chairman of the electric light committee of the New England Insurance Exchange, then spoke of the fact that to-day his friends did not feel the anxiety about the fire hazards of electric wires they once felt, because of the improved methods of work induced by the action of the New England Electric Exchange. He said that a notice should be at once sent out to every electric company in New England allowing thirty days within which to join the Electric Exchange, failing which, a new inspector might be appointed and an assessment levied on such companies to defray the expenses of such inspection. Thereafter he would do all in his power to take off such assessment. Captain Brophy then spoke a few words in praise of the excellent work done by the Exchange. Mr. Cram then moved "that the board of directors be given full discretion to modify or change the plan of license of the New England Electric Exchange," to provide for the possible discontinuation of inspection by the insurance people. The motion was carried.

A motion was also passed that $200 be paid to the secretary as a partial acknowledgement of his services. The motion was unanimously carried. A vote of thanks was then passed in favor of the retiring officers, which was suitably acknowledged. Mr. Wright will enter upon his duties as president at once, and as he is known to be a hard and assiduous worker, the future success of the Exchange is assured. Mr. Fairbanks is also a general favorite, and has a host of friends in New England who will doubtless give him a cordial reception and warm backing in his new field.

The annual meeting of the stockholders of the Thomson-Houston Electric Co. was held at Middletown, Conn., at which more than three-fourths of the stock of the company was represented. The report of the treasurer was read and accepted. The following named gentlemen were elected directors for the ensuing year: H. A. Pevear, C. A. Coffin, B. F. Spinney, C. H. Newhall, E. Thomson, S. A. Barton, J. N. Smith.

Mr. F. E. Cabot has been appointed as Mr. Killecutt's successor, as chief inspector of the Boston Fire Underwriters' Union. The duties are not new to Mr. Cabot, as he has assisted Mr. Killecutt for some time.

Mr. E. C. North has been appointed as successor to Mr. S. E. Barton, as chairman of the electric light committee of the New England Insurance Exchange. Mr. North's experience with insurance matters is an extensive one, and he now represents in Boston the Merchants' Insurance Company of Newark, N. J. Mr. North appeared last Monday at the annual meeting of the New England Electric Exchange, and said a few words about the proposed work of the Exchange from an insurance point of view, and made an excellent impression in the members present, as an advocate for good electric construction work.

The Long Distance Telephone Company gave an interesting exhibition this week of the extreme accuracy and delicacy of their instruments, by putting their line in connection with their instruments in the Lenox Lyceum, New York City. In that building they have run wires from the Casino, and the notes of the fair Lilian Russell can now be distinctly heard in Boston by those who care to pay about $1.50 for five minutes' use of the 'phone. Among those who have availed themselves of the opportunity is Mayor Hart, who heard the music at his residence on Commonwealth Avenue.

Commodore Farquhar of the United States navy has been inspecting the Thomson electric welding process with a view to determining the advantages of combining lighting and welding in the various navy yards.

Experiments have been made in the Thomson Welding Company's factory at Lynn, with alternating dynamos, having converters for incandescent lamps and welding machines, all on the same circuit. Even when the current is suddenly turned on to make a heavy weld, the lamps were not noticed to reduce in candle power, a momentary flicker being all that was discernible. The experiments go to show that undoubtedly welding and lighting can easily be operated on the same circuit. This opens a large field for welding machines, which can be placed in almost any store for welding purposes, and operated by passing electric currents.

The committee on mercantile affairs continued its hearing on the control of the electric wires, the time being given to the remonstrants.

Arthur Lord appeared as counsel for the Western Union Co., F. A. Wyman for the Westinghouse Co., G. A. Bruce for the Bell Telephone Co., E. W. Burdett for the Electric Light Association, and W. W. Gooch for the Edison Local Co. Prentiss Cummings, counsel for the West End Co., had no objection to the tagging of wires, but would want an opportunity to examine any bills which might be offered to the committee. Mr. S. L. Powers for New England Telegraph and Telephone Co., presented a bill to compel the working of every wire in a public street in Boston and to empower the removal of any unworked wire after October 1, 1890. City Solicitor Bailey of Boston offered a bill providing for a thorough inspection of all electric wires and for the removal of all which are deemed to be unsafe. It requires the owners of wires to see that they are thoroughly put up and protected, and compels them to be tagged once in every 100 feet with a tag showing the owner and electric capacity of the wire. It covers all wires, whether electric or not, and applies to all parts of the State.

The Street Railway Committee has ended the series of elevated railroad hearings, and the outcome is now looked forward to with interest by all. A decision is expected within the next ten days.

The board of aldermen gave a public hearing this week for the general expression of sentiment on the speed of the electric cars. A great deal of dissatisfaction has arisen as to the slow speed, and there were quite a number of prominent business men who appeared in favor of granting an increased rate of speed. As the speed stands to-day electric cars are undoubtedly of little use to the great working public as a means of rapid transit from their homes in the suburbs to the centre of the city. There were a few remonstrants to the granting of an increased rate of speed, but they were sadly in the minority, and it is a foregone conclusion, that the speed will be increased.

Boston, April 19, 1890.

CHICAGO.

Electro-Thermic Manufacture of Watch Springs—A City Lighting Department—Death of Mr. H. A. Glasier.—Lecture by P. Atkinson.

Messrs. Fred. Purdy and Harry Procemier, of Oak Park, one of Chicago's suburbs, have recently perfected a method of tempering watch springs by electricity. After two years of hard and unremitting experiments, and an expenditure of upwards of $25,000, this process is now thoroughly successful. In watch springs manufactured by the old methods numerous troubles existed by reason of the variations of hardness and in thickness entailed thereby. It was impossible to roll a ribbon of steel without variations, up to half of 1,000ths of an inch. By the new electric method these difficulties have been completely overcome. The machinery for manufacturing these springs is automatic, and the hardening is rendered uniform and controlled as desired. It is claimed that a watch spring made by this electro-thermic process possesses an elasticity five to ten per cent. greater than one produced by the ordinary methods of tempering, and by its means a spring is obtained of equal strength and proportionately thinner and having a graduated temper heretofore unattainable, the inner end being made soft and becoming gradually harder as the outer end is reached, whereby the liability to breakage is greatly reduced. The American Spring Company are manufacturing these springs, which, on account of their many points of excellence, will undoubtedly meet with widespread adoption.

Owing to the great increase in the city lighting by the wide employment of the arc light a separate lighting department is now being organized by the city authorities, which will embrace electric lighting, gas and oil. This action has been rendered imperative on account of the continually growing business of this branch of city affairs. Professor Barrett and the present street commissioners, will be the commissioners of this new department, which will be in shape by the first of next month.

It is with deep regret we note this week the sudden death of Mr. H. A. Glasier, the western representative of the J. A. Grant Engine Co., and a member of the Chicago Electric Club, which occurred in the early morning of April 15. Mr. Glasier was not feeling well the afternoon before and returned to his home. His death was occasioned by heart disease. He was a man esteemed and liked by all his acquaintances, and a member whom the club will deeply miss.

Philip Atkinson, Ph. D., delivered the third of his course of four lectures on electricity at the Chicago Athenæum last week. The subject for the evening was "The Storage Battery." The lectures are arranged especially for the benefit of pupils of the Mechanics' Institute and are free to all. A large audience listened attentively to D. Atkinson.

Chicago, April 19, 1890.

PITTSBURGH.

Increasing the East End Plant.—Westinghouse Electric Railway Work.—A City Electrician.—Electric Cars for Funerals.

The East End Electric Light Company of this city is about to double its capacity to meet the increased demand for electric light in Pittsburgh. A number of the outer wards and suburban towns are this time to be covered with electric light. Mr. A. T. Rowand, the president of the company, has purchased a four-acre lot in the Twenty-third ward of the city, on which site the power-house is to be erected. This will be used to supply both arc and incandescent lamps, which will light up Marion, Hazelwood, Glenwood, Homestead, Hays Station and Munhall along the Monongahela river. Another central station plant is to be erected at Sharpsburg for the purpose of supplying light to that borough as well as Etna, Willow Grove, Millvaleborough and other smaller places along the Allegheny river. This company uses the Westinghouse alternating current system of arc and incandescent lighting, and the plant in the East End has now a capacity of 800 arc and 20,000 incandescent lamps. When the proposed extensions are completed the various stations will be in shape to furnish about 40,000 incandescent lights and 2,000 arc lights. Work on this big improvement will be started at once and pushed until all the places mentioned are connected with the system. In this connection it might be mentioned that Pittsburgh has at present more electric lights in use, proportionately speaking, than any other city in the country. The cost of these extensions of service will be quite large, but the company is determined to give its patrons first-class service regardless of expense.

The Westinghouse Electric Company is about to enter another field of electrical construction, which will necessitate the enlargement of the company's plant to a considerable extent. The company has just concluded the arrangements to commence the manufacture of street car motors and such other appliances incidental to the construction of electric street railway work. The motor department has already been set to work to its fullest capacity, and work is turned out day and night. Whether, however, this branch of the business will be definitely carried on in Pittsburgh, or whether a special shop is to be erected in Wilmerding has not yet been decided. There is no doubt that this will open a very large avenue for increased business to the company.

The Birmingham Traction Company has now definitely decided to introduce an electric system on its street car line. This may be considered a victory for electricity, because for a long time it was said that the company intended to make a cable road out of its line. Work on the changing of the track has already been started and the cars are to be running by next October.

The Allegheny police committee met a few nights ago and elected an electrician to take charge of the wires of the patrol service, a duty that will require all of his time for some months. Ever since the work has been given up by Chief Jones, of the fire department, the wires have been wholly unreliable. Lately they have become worse than ever, and when an officer makes an arrest now he takes his prisoner to the nearest telephone and calls for a patrol wagon through the mayor's office instead of calling from a patrol box. At the meeting last night, Mayor Pearson called the attention of the committee to the matter, and handed in a number of applications from persons desirous of being appointed to look after the wires. The matter was not unfamiliar to the committee and they united on the name of H. E. Dillon, an electrician of 10 years experience, who had a number of letters of recommendation. He will be considered a police officer, with the same pay, but will only be required to look after the patrol telegraph wires.

The New Brighton and Beaver Railway Co. and the Beaver Valley Street Railway Co. have consolidated. They will now build an electric road and extend their line to Beaver, a distance of seven miles.

The teamsters of Pittsburgh and Allegheny and the motor men of the Pleasant Valley Street car line are just now at daggers drawn. The former claim that the motor men run their cars too fast, and will not give the teamster a chance to get his vehicle out of the way.

Pittsburgh is, perhaps, the only city in the Union that can boast of the distinction of having electric cars used as funeral carriages. But such is really the case. The Suburban Electric Railway Co. of the Southside, which passes several cemeteries, has adopted this custom, and is now putting its regular chartered cars at the disposal of funerals.

All the machinery for the new apparatus for the city bureau of electricity is to be shipped this month, and Mr. Morris Mead, the city electrician expects to have the apparatus in operation in the fall.

Zanesville, O., is the latest convert to electricity. The Zanesville Electric Street Railway Co. has been incorporated with a capital of $50,000.

Pittsburgh, April 18, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.

ELECTRIC TRAMWAY DATA.

[123.]—I notice an error in the printing of my paper in your last week's issue; on page 239, "Central Station Cost, Maintenance, Carmen=" Cost" per car mile,"—should be "Central Station Cost, plus Maintenance, plus Carmen—" Cost per car mile." Moreover the sentence immediately following should have been omitted from, "The carmen" * * to "very small."

A word, too, seems necessary as to the apparent inconsistency shown in columns 4 and 5 of table I.; taken together they indicate an efficiency of about 125 per cent.

The data is given just as it came without any attempt to reconcile such obvious inconsistencies. The friction card which is deducted from the average indicated horse-power is undoubtedly too high, for it includes the current for all lamps burning in offices, car house, power house, etc. The friction cards were taken the last thing at night when lights were all burning; but many of these lights burn all day and are taken into account in station electrical readings, whereas in mechanical readings this power for lights is deducted; *i. e.*, the electrical and mechanical power, taking columns 4 and 5, is not for the same load; both the addition of "lights" to the electrical power and deduction from mechanical power cause the ratio to be in error in the same direction. In tests made as these were, by one man without skillful assistance, and with only such facilities as the local companies could afford, no very great accuracy is to be expected. Lamps could not all be put out during the day, nor could a friction card be taken excluding all lamps; in other words, the entire routine of the station could not be subordinated to these tests.

NEWS AND NOTES.

COLLEGE NOTES.

Columbia College.

The new building which was erected for the accommodation of the Electrical School has now been fitted up specially for the purpose and contains a number of interesting features. The facilities for obtaining electric current of different kinds and in large quantities are particularly satisfactory. Continuous current to the amount of one hundred amperes, under pressure of either one hundred and ten or two hundred and twenty volts, may be had at numerous points in all the rooms from a specially installed circuit of the three-wire system connected with the 39th street Edison Station. Available at adjacent points and parallel to this circuit is another special circuit of equal capacity on the two-wire system coming from the Edison dynamos of four hundred lights total capacity placed in the cellar. A third special circuit also of one hundred amperes capacity has been put in to connect dynamos, motors, etc., in the electrical workshop, down stairs, with measuring instruments in the upper laboratory, which is devoted to delicate work. A storage battery circuit available at convenient points in the various rooms is to supply current under an E. M. F. of a few volts for testing purposes, galvanometer work, electrolysis and the many other duties which are generally performed in the laboratory by a number of separate primary batteries and their attendant inconveniences. The buildings are lighted entirely by electricity from the regular circuits. Gas for heating and other purposes may be had, wherever needed, from pipes fitted around the walls of each room, just below the ceiling.

The connection with the Edison Central Station is of great convenience as current can be obtained and experiments carried on continuously without regard to the usual noon and evening stopping of machinery, which is such a scource of annoyance in this work. In one particular case a current was used with absolutely no interruption night and day for almost a week. The connection with the Manhattan company's alternating circuit has lately been cut off by the city authorities, but alternating current and arc light dynamos are soon to be put in in order to avoid this unpleasant contingency. To avoid as much as possible any jarring, the tables for the support of instruments have no connection with the floor, but are fastened directly to the brick walls.

The course of instruction may be divided into two branches, the practical and the theoretical. As so much of the progress that has been made in electrical science has been due to theoretical considerations, and as everything points to the fact that the electrical engineer of the future must be a theoretical as well as a practical man, the study of mathematical physics and the theory of electricity has been introduced as a necessary part.

The first session of the first year in the practical course is given up to the study of the fundamental principles of electricity which deserve more attention than they generally receive. In the theoretical branches of the subject are studied, the theory of electric potential, electrostatic distribution and induction, theory of the condenser, dielectric polarization, etc. The theory of electrical measurements starts with the principles of the conservation of energy, Joule's law, etc., and then passes to the construction, performance and use of electrical measuring apparatus of all descriptions. Transmission dynamometers and the methods of mechanical measurement are also treated. Co-ordinate with this theoretical instruction, the entire afternoon of each day is spent in practical laboratory work in electric measuring and testing.

In the second session the work is more advanced. On the practical side the construction and operation of dynamos and motors are studied carefully and minutely; also arc and incandescent lamps, telegraphs, telephones, primary and secondary batteries, etc. In the mathematical theory the students take up the study of the laws governing constant electric flow in linear conductors, theory of thermo-electricity, magnetism, electro-magnetic induction, Maxwells's dynamical theory of the electro-magnetic field, etc. The instruction in the theory of the dynamo and motor includes the characteristic and current curves of the different types of machines, construction and use of diagrams in practical work, determination of the different efficiencies, the theory of constant potential and constant current machines, etc. The laboratory work carefully follows up this instruction, and consists in the testing of dynamos, motors, batteries, etc., and also gives the students practice in the actual construction of simple electrical apparatus. Frequent visits are made to electrical factories, plants, and stations.

The practical lectures of the second year are devoted to the management of dynamos, motors, engines, etc., electric lighting plants and stations, electric power, the construction and use of submarine, quadruplex and other telegraphs, the extraction, deposition and purification of metals by electricity and the theory of primary and secondary batteries. The mathematical course comprises the theory of varying currents and alternating current induction. The theory of the dynamo and motor covers the study of the alternating current dynamo and its characteristic, periodic currents, measurement of mutual and self induction, methods of measurement of alternating currents, transformers, etc. In the laboratory and workshop, practice is given in taking apart, putting together, and repairing of dynamos, motors, measuring instruments, and in the construction of electrical apparatus, such as winding armatures, etc.

Conferences are held one evening each week throughout the course to discuss current electrical literature.

The students have just finished the construction, for experimental purposes in the laboratory, of a battery of 1,280 cells which, when set up with Daniell elements, gives an E. M. F. of about 1,400 volts, and when set up as a storage battery an E. M. F. of about 2,800 volts. Some interesting results have been obtained from the experiments performed with this battery.

There has just been erected in the mechanical engineering department a hydraulic testing machine of 150,000 pounds capacity, and it is now to be used by the electrical engineering students for a series of tests, which, it is expected, may be of considerable theoretical and practical interest in electrical science.

SOCIETY AND CLUB NEWS.

NEW YORK ELECTRIC CLUB.

The election of officers at the Electric Club took place on April 17. The successful candidates were as follows: *President*—O. E. Madden; *Vice Presidents*—Grosvenor P. Lowrey, Erastus Wiman, A. H. Patterson, W. D. Sargent; *Secretary*—Charles W. Price; *Treasurer*—Willard L. Candee; *Board of Managers*—J. C. Chamberlain, H. L. Storke, John J. Carty, Cyrus O. Baker, Jr., J. H. Herrick, C. H. Barney, A. D. Stanley, H. C. Adams, George B. Coggeshall, Samuel Insull, John A. Seely, C. E. Stump, Henry A. Reed; *Committee on Membership*—Henry Hine, Lieut. F. W. Toppan, F. Z. Maguire, George T. Manson, and George Worthington.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the Council of the Institute on April 15 the following gentlemen were elected to associate membership: G. W. Palmer, Jr., General Manager, McKeesport Light Co., McKeesport, Pa.; W. F. Bauer, Constructionist, The Electrical Accumulator Co., 62 Steuben street, Orange, N. J.; George B. Shaw, General Manager, National Electric Manufacturing Co., Eau Claire, Wis.; J. J. Carty, Electrician, Metropolitan Telephone and Telegraph Co., 18 Cortlandt street, New York; Arthur Churchill, Electrical Expert, Frazar & Co., Yokohama, Japan; Warren S. Belding, Electrician and Superintendent, The Belding Motor and Manufacturing Co., 6423 Stewart Boulevard, Chicago, Ill.; Herbert H. Eustis, President and Electrician, Eastern Electric Cable Co., 61 Hampshire street, Boston, Mass.; Marmaduke Burrell Holt, Student, Course of Electrical Engineering, Columbia College, New York; W. D. McQuesten, Electrical Engineer and Contractor, 15 Cortlandt street, New York.

THE LANGHANS INCANDESCENT LAMP.

The main characteristics of the Langhans incandescent lamp, recently brought out in England, are the low vacuum it requires and the employment of a metallic filament coated with silicium. As a vacuum corresponding to about one millimetre is all that is necessary, it can be produced by a mechanical vacuum pump specially constructed for the purpose by Mr. Langhans. The several processes employed in coating the filaments with silicium are said to be simple, inexpensive, and to permit of a high degree of accuracy in predetermining the voltage. The life of the Langhans filament at 2.75 watts per candle-power is said to be equal to that of the best carbon makes. Ordinary carbon filaments can be coated with silicium by the Langhans process, and it is claimed that they then require less current in order to give the same amount of light, and can be made to work satisfactorily in the same low vacuum as the Langhans filament proper.

WORDS OF GREETING.

THE ELECTRICAL ENGINEER, beginning with this month, becomes a weekly. This journal is one of the oldest of its class, and is undertaking the extra work involved in a weekly publication under exceptionally favorable conditions, through having now associated with their editorial staff Mr. T. Commerford Martin and Mr. Joseph Wetzler, long and widely known in electrical journalism.—*Architecture and Building.*

Our famous New York contemporary, the *Electrical World*, loses two men in Messrs. T. Commerford Martin and Joseph Wetzler, whose worth and ability cannot be excelled. Mr. Martin, from his long connection with the *World* in the capacity of associate and managing editor, has a personal historical knowledge of the development of electrical science possessed by few in this country. His efforts, which were so ably seconded by Mr. Wetzler, will now be turned to the advancement of THE ELECTRICAL ENGINEER, of the same city. Mr. Wetzler goes with him.—*Practical Mechanic.*

The publishers of THE ELECTRICAL ENGINEER announce that this publication will be issued weekly instead of monthly, beginning with the first week in April, and that it will give its attention distinctively to the great engineering problems and questions of electricity, proposing to "cover the whole domain of theoretical and applied electricity that its name implies." Numerous contributions from leading electricians and illustrations of the first order are promised. THE ELECTRICAL ENGINEER, which has already attained a high reputation in its specialty, is now conducted by Messrs. George M. Phelps, T. Commerford Martin and Joseph Wetzler.—*Railway Age.*

The growing importance of electrical interests is made manifest when a technical paper of the standard maintained by THE ELECTRICAL ENGINEER can be published weekly. It is a thoroughly scientific journal, not a mere repository of electrical items, and is of great value to students of electricity. Its editors are men of attainments, and its contributors are men whose names are inseparable from the development of electrical science.—*Boston Transcript.*

We are glad to find that this excellent paper is now to appear weekly instead of monthly as heretofore. Messrs. T. C. Martin and J. Wetzler, who have so ably edited another of our American contemporaries, will now conjointly conduct THE ELECTRICAL ENGINEER, and we wish them the best of success in their congenial occupation. Mr. Martin is, we believe, an Englishman, although personally not so well known in this country as his colleague Mr. Wetzler, who visited England so recently as the autumn of last year. Under their combined influence THE ELECTRICAL ENGINEER, as a weekly publication, should soon become the leading paper of the eastern part of the United States. —*London Electrical Review.*

A SUPPER SERVED BY ELECTRICITY.

A special dispatch from Baltimore, of April 11, says: "The Baltimore Bicycle Club gave an electrical dance and banquet tonight at the new club house. G. E. Painter, ex-member of the club, and an electrician, by an ingenious arrangement of wires produced some novel electrical effects. Two sets of musicians furnished the music. The dancing rooms were connected by folding doors. The musicians sat in the hall and the electric annunciators told them what dances to play, the leader of each set of dancers simply touching electric buttons in their respective rooms. In the supper room there was a track of small brass rails, on which was an electric car or basket about a foot long and thirty inches wide. This car conveyed the viands from the butler's apartment. The butler placed the courses in silver trays upon the car and sent them along the electric railway. The car stopped long enough in front of each plate for each guest to help himself. The car was also supplied with electric bells. The ballroom was beautifully illuminated by incandescent lights in the shape of tulips, lilies and other flowers. Under the tables were music boxes operated by electricity which played during the supper. Not a drop of coffee or a bit of ice cream was spilled by the electrical waiter."

LIGHTING THE U. S. CRUISER "NEWARK."

The Thomson-Houston company have obtained the contract for lighting the new cruiser "Newark." In connection with this the Armington & Sims Engine Co. have received an order for three double upright 7 x 5 engines. They are to be strictly of the marine type with many new improvements, giving the greatest amount of power for the least weight and area of floor surface. They will not be compound, as recent and exhaustive experiments by the French and English Navy Departments, it is said, condemn the small compound engines for ship lighting, and this contract has in a measure been awarded and based on their experience.

LITERATURE.

Fifth Annual Report of the Board of Gas and Electric Light Commissioners of the Commonwealth of Massachusetts. January, 1890. (Pub. Doc. No. 85.) Boston, 1890.

In 1885, the Legislature of Massachusetts established a Board of Gas Commissioners, for the purpose, mainly, as it appears, of regulating the relations between the gas companies and the public. The statute provided that every such company should make an annual return to this Board, showing its financial condition, and its current receipts and expenditures, and upon request should furnish any other information required by the board concerning its condition, management and operations. The board was further authorized to pass such orders, and take such action as it might deem necessary, in respect to regulating the quality or price of gas furnished by any company, upon the complaint made in writing, either of the authorities of any municipality or of not less than 20 consumers. By additional legislation in 1887, the jurisdiction of the Board was extended over all chartered electric light and power companies operating in the state, and it was provided that no such company should place its conductors in the streets of any municipality, except by consent of the local authorities given after a public hearing with due notice to all interested; and also that any party aggrieved by the decision of the municipal authorities might appeal to the Board whose decision should be final. In 1887, chartered gas companies were authorized to supply electric light within their territory, subject to the assent of the holders of two-thirds of the stock and to the approval of the Board; and under like restrictions were authorized to purchase the property and franchises of existing electric light and power companies within their territories.

The present report of the Commission is the third issued since its jurisdiction was extended over electric light companies; and brings the returns down to June 30, 1889. The Commissioners say that they have endeavored to keep in mind the welfare of the communities in which they have been called to act, and that they approve of the general policy of the Legislature in permitting but one company to do the lighting in the smaller cities and towns, mainly for the reason that the number of such companies which can conveniently do the business must necessarily be limited, owing to the nature of the work, and to the fact that much of it must be done in the public streets. In pursuance of this policy the Commissioners state that they have been compelled, in several instances, to deny to competitive companies the privilege of going into business, the only exceptions being when it was clearly shown that the new company could supply the community better and more cheaply than the existing ones. The number of chartered electric light and power companies in the state already considerably exceeds the number of chartered gas companies, the figures being as follows:—

Electric light and power companies	100
Gas companies	75

Of these gas companies, 26 are permitted to supply electricity.

The question of the comparative safety of water and coal gas is discussed *in extenso*. According to the best information obtainable, the number of deaths in the United States, from inhaling illuminating gas during the year 1889, is 107, of which at least 30 were suicides. It is worthy of note that 46 of these deaths occurred in hotels. The conclusion reached is that water-gas, either alone or mixed with coal-gas, is somewhat more dangerous than coal-gas alone, but the report suggests with much reason, that even if a thing in itself be dangerous, the very knowledge of this danger tends to prevent harm, by inducing a greater degree of care than would otherwise be exercised. A modification of the restrictions imposed by the present law upon the manufacture of water-gas is recommended.

The following figures which are compiled from the returns of several of the largest companies, throw some light on the much mooted question of the actual cost, per cubic foot, of coal-gas in the holders:—

Gas coal	42 to 43 cents	
Oil	3 to 7 cents	
Residuals (deducted)	13 to 23 cents	
Net cost of materials		20 to 30 cents.
Labor		14 to 20 "
Repairs		5 to 8 "
Total		39 to 58 "

The aggregate receipts for gas sold by meter, notwithstanding a general reduction in average price, show a gain in 1889, of $127,000, while receipts from street lights fall off about $44,000, or 11 per cent. This indicates that the electric light, while affecting the gas companies' street lighting, has not as yet reduced their receipts from sales by meter.

A large amount of statistical matter is given in detail in tabular form, the usefulness of which might have been materially enhanced by a more extended and intelligent summarization of the results. Separate statements showing the financial condition of each gas and electric light company are given in an appendix, and in the case of the gas companies the yearly statement of profit and loss, which for some reason not explained, is omitted in the case of the electric light companies, both individually and in the aggregate. Although no figures are given which directly show the cost of electric light operations, it might be possible to arrive at them indirectly with some accuracy, if it were worth while to do so. The aggregate assets and liabilities of the gas companies, and the results of the year's operations are summarized in the following table, which we have compiled from the figures given in the report:—

GENERAL BALANCE SHEET.

Total assets of all the companies		$20,930,666 07
Capital stock	$12,705,000 00	
Bonded debt	346,100 00	
Other indebtedness	5,324,442 64	
Total liabilities		18,375,542 64
Reserve funds and surplus		$2,555,123 43

PROFIT AND LOSS ACCOUNT FOR 1889.

For gas sold by meter	$4,027,049 67	
For gas supplied public lamps	352,934 84	
For sales of by-products, etc	489,357 60	
Total gas receipts year ended June, 30, 1889.		$4,869,342 11
Total expenditures of all kinds,		3,314,337 98
Leaving a net profit on gas business.		$ 1,555,001 13
To which add receipts from electric lighting.		54,318 62
And from other sources		80,621 83
Total receipts from all sources		$ 1,689,944 58
From which were paid dividends aggregating		1,086,884 12
Leaving surplus to be carried forward of		$608,560 46

The assets and liabilities of the electric companies, as given, show an aggregate capital of $4,837,085, and a total bonded and floating debt of $1,643,936. An examination of the returns in detail, shows that a large number of the electric companies have been started with a wholly insufficient capital, and in not a few instances it may be feared that, their borrowing capacity having been exhausted, they are confronted with a large business which they have neither the plant nor the capital to handle properly. The gas companies have apparently been, as a rule, much more conservative in this respect. We have made up the following summaries from the figures given which will be found of interest:—

Dynamos,

Aggregate number of dynamos	368
Aggregate rated horse power of dynamos	29,818

Dynamo Capacity.

2,000 c. p. lamps (arc)	7,103
1,200 c. p. lamps "	4,301
1,500 c. p. lamps "	165
800 c. p. lamps "	140
16 c. p. lamps (incandescent)	80,955
20 c. p. lamps "	8.400

Arc Lamps.

Number of single arc lamps	5,463
" " double " "	3,375
Total	8,838
Commercial arc lamps	3,916
Public arc lamps	4,922

Meters.

On arc circuits	111
" incandescent circuits	379
" power circuits	48
Total	538

Incandescent Lamps.

Commercial incandescent lamps. (Of which 2,438 are on arc circuits.)	72,419
Aggregate horse power of electric motors (stationary)	1,442

Arc Carbons Used During the Year.

Plain	986,473
Coppered	2,976,666
Total	3,963,139

From the above figures it appears that nearly the full rated capacity of the incandescent dynamos is employed.

If we assume that the actual number of lamp hours is 12 per cent. of the maximum, which is probably not far from the truth, the light given by 72,419 incandescent lamps in one year is equivalent, in round numbers, to about 381,000,000 feet of gas.

Nearly all the incandescent lamps in the state, except those of the Edison companies, at Boston, Brockton, Fall River, Lawrence and New Bedford, are run on a "contract" and not on a "meter" basis. Sixteen candle incandescents are ordinarily charged at 1¼ cents per hour by meter, and $10 to $12 per annum on contract. For arc lights the price is variable, all-night lamps, seven nights per week, being charged from 40 to 65 cents per night, 50 cents being perhaps the most usual figure; or by the year at $180. For shorter hours a proportionate sum is charged.

The figures in this report are quite sufficient to show that in the contest between the gas and electric lighting industries, the latter are not by any means going to have a "walk-over," although the field open to them is much better in some towns than in others, as will appear for example by comparing the returns in Worcester and Lowell, two cities of approximately the same population. In the former the sales for the year amounted in round numbers to 105,000,000 feet, and in the latter to 200,000,000 feet, the average price in Worcester being $1.50, and in Lowell, $1.10 per thousand. If space permitted we might point out a number of other matters which are equally well worthy of consideration.

OBITUARY.

Johann Georg Halske.

We regret to record the death of Johann Georg Halske, the co-founder and, for many years, partner of the well-known firm of Siemens & Halske. He was born at Hamburg on July 30, 1814, and went to Berlin, where he set up an engineer's shop in 1844. Soon after, he made the acquaintance of Werner Siemens, who, in Halske's workshop, assisted by Halske's mechanical skill, was able to work out his first inventions in telegraphy, so as to bring them before the public. In 1847 the two men entered into partnership, and laid the foundation for the electrical industries which at the present day give employment to thousands of workmen, both at Berlin and Charlottenburg, and at several branch establishments. Halske left the firm in 1867, and since then has been an active member of the municipality of Berlin.

LEGAL NOTES.

EDISON ELECTRIC ILLUMINATING CO., OF PATERSON, N. J., vs. J. STRIEF.

The Edison Electric Illuminating Co., of Paterson, N. J., lately brought suit in the District Court against Jacob Strief, alleging that seven Edison lamps had been installed on defendant's premises, in consequence of an agreement by the consumer to pay for the service as per "meter bill." The first bill rendered for a month's use amounted to $34.40, and payment of same was refused. In court defendant maintained that he had never "given an order for the installation of the lights, and that as he did not use them all, he did not see why he should be asked to pay for the installation of the lights and for more current than he used." The Court, however, found that even though there was no contract, still his usage of the lights made him responsible for the installation of them, and of course he must pay for the amount of current used as indicated by the meter of the company. This showed the amount claimed ($34.40) to be correct, and judgment was accordingly given for the plaintiffs.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued April 15, 1890.

Alarms and Signals:—*Signal-Box*, M. Martin, 425,576. *Electric Call*, J. B. Currier, 425,594. *Electric Call*, D. H. Rice, 425,630.

Conductors, Insulators and Conduits:—*Insulator*, W. P. Kookogey, 425,513. *Insulating Compound*, A. A. Knudson, 425,615. *Wire Conduit*, A. J. Smith, 425,918. *Electric Conductor*, E. Tortora, 425,917. *Electric Conductor*, P. Seubel, 425,961.

Distribution:—*Distribution of Electric Currents*, E. Thomson, 425,470.

Dynamos and Motors:—*Brush-Holder for Dynamo Electric Machines*, F. A. La Roche, 425,435. *Commutator for Dynamo Electric Machines*, T. A. Edison, 425,763. *Method of Operating Synchronous Alternating Current Motors*, C. Zipernowsky, 425,923.

Galvanic Batteries:—L. M. J. C. C. Renard, 425,959.

Lamps and Appurtenances:—*Cut-Out*, C. Batchelor, 425,726. *Incandescent Lamp Socket*, J. J. Bradley, 425,741. *Incandescent Lamp*, T. A. Edison, 425,761. *Cut-Out for Incandescent Electric Lamps*, T. A. Edison, 425,762.

Measurement:—*Electric Meter*, V. Popp, 425,579. *Measurement of Electricity in Distribution Systems*, T. A. Edison, 425,760.

Miscellaneous:—*Electric Snap-Switch*, C. J. Hamilton, 425,507. *Thermo-Electric Battery*, J. Edelkamp, 425,568. *Cloth-Cutting Machine*, M. Hofheimer, 425,572. *Electric Temperature Controller*, E. H. Parker, 425,625. *Electric Door-Opener*, W. L. Godfrey, 425,777. *Phonograph Recorder*, J. H. White, 425,840. *Electric Switch*, E. P. Warner, 425,963.

Railways and Appliances:—*Car Telegraph*, W. F. Stevens, 425,466. *Contact Device for Electric Railways*, F. O. Blackwell, 425,488. *Electric Railway Contact*, F. O. Blackwell, 425,489. *Method of Transferring Batteries*, W. B. Cleveland, 425,493. *Electric Car Motor*, E. Peckham, 425,627. *Guard for Electric Railway Trolleys*, E. Thomson, 425,640. *Safety Attachment for Electric Railway Trolleys*. F. C. Wheeler. 425,720. *Electric Heating Apparatus for Electric Railway Systems*, M. W. Dewey, 425,757. *Electric Railway*, T. A. Evans, 425,767. *Electric Railway Car*, M. W. Dewey, 425,866. *Electrically Propelled Car*, R. M. Hunter, 425,883. *Electric Railway*, R. V. R. Sill, 425,911 and 425,912. *Electric Railway*, W. H. Knight, 425,950. *Electric Railway System*, D. G. Weems, 425,964. *Electric Railway*, D. G. Weems, 425,965 and 425,966.

Secondary Batteries:—*Secondary Battery*, J. F. McLaughlin, 425,818. *Secondary Battery Electrode*, J. F. McLaughlin, 425,819. *Secondary Battery*, G. Philippart, 425,902 and 425,957.

Telegraphs: *Balanced Pen for Autographic Telegraphs*, H. Etheridge, 425,413. *Telegraph Transmitter*, F. W. Jones, 425,511. *Receiving Apparatus for Cable Telegraphy*, P. B. Delany, 425,597.

Telephones and Appliances:—*Telephone Bell and Connection*, D. H. Rice, 425,631. *Electric Circuit for Telephone Purposes*, A. W. Berne, 425,853. *Multiple Telephony*, J. J. Carty, 425,862. *Telephone System*, J. J. Carty, 425,868.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

A LARGE NUMBER OF NEW STREET RAILWAY CONTRACTS.

We understand that the Sprague Electric Railway and Motor Co. have closed a large number of contracts for the electrical equipment of street railways during the last month. These contracts came from all over the country, a large number of them being noticeably from street railway companies which already have a number of cars in operation upon the Sprague system.

No argument as to the popularity of electric railways could be made more convincing than this fact, which is so common, of additional equipments ordered by street railway companies where the system has been tried. When a company continues to order additional equipment there is only one conclusion to be drawn, *i.e.*, that the system is a success.

The most recent contracts in regard to the Sprague company are as follows:—

Augusta Street Railway, Augusta, Ga., 16 car equipments: Paducah Street Railway, Paducah, Ky., 9 car equipments; Fort Worth & Arlington Heights Railway, Fort Worth, Tex., 3 car equipments; Troy (N. Y.) & Lansingburgh Railway, Troy, N. Y., 12 car equipments; Metropolitan Railway, Portland, Oregon, car equipments; Passenger & Belt Railway, Lexington, Ky., 4 car equipments; Atlantic City (N. J.) Electric Railway 1 car equipment; Detroit (Mich.), Rouge River Dearborn Railway, 4 car equipments; Union Street Railway, St. Joseph, Mo., 6 car equipments; Sioux City, Ia., Street Railway, 5 car equipments; Dallas (Tex.) Rapid Transit Railway, 1 car equipment.

DAY'S "KERITE."

Mrs. Sarah A. Day, the administratrix of the estate of A. G. Day, deceased, has now issued an announcement of the fact that the large business known under the name of Day's "Kerite" will be carried on as before, and that Mr. George B. Prescott, Jr. has been appointed general agent, assuming charge at once, at 16 Dey street, this city. Mr. Prescott also issues a circular, in which he advises his personal, professional and business friends of the new departure, and hopes "that the users of 'Kerite' will continue to approve its qualities as they have so generally done in the past, and that all others who desire a trustworthy and durable insulation, that has been successfully employed for aerial, subterranean and submarine purposes for upwards of 25 years, will test its merits."

THE SHAVER MOLECULAR TELEPHONE.

There can be no mistake as to Mr. H. H. Warner's intention to push the Shaver "Molecular" telephone, which has recently been illustrated and described in these pages. Following his well-known and successful methods of attracting and holding public attention, he has issued no fewer than *ten* million circulars on the subject, thus reaching, it may be said, every adult in the United States. We believe that no invention ever before was the subject of such publicity, or at one time was brought so prominently and persistently to the notice of possible patrons. Mr. Warner sees that 300,000 people appreciate their telephones highly, and he proposes to be a benefactor by supplying the wants in this respect of at least 3,000,000 more. With regard to the efficiency of the Molecular apparatus, the Shaver Corporation publish in this issue in our advertising pages a fac-simile of the Government specification—which we have seen—in which their telephone is named and called for as the standard. It is a striking piece of testimony to its value.

W. R. OSTRANDER & CO.

Owing to the great increase in their business, W. R. Ostrander & Co. are compelled to remove their offices from Ann street, and on May 1 they will locate at 195-197 Fulton street, three doors west of Church street, where they will carry in stock a full line of speaking tubes, whistles, electric, mechanical and pneumatic bells, annunciators and general bell-hangers' supplies. Not long since the factory facilities were greatly increased by Mr. Peck, so that the concern is now in good shape to fill the largest orders.

PAGE BELTING.

The Page Belting Co., of Concord, N. H., manufacturers of leather belting in all the staple grades, also manufacturers of the following specialties: the "Acme Link," the "Eureka" dynamo belt, also lacing, both tanned and raw hide, report a very large increase in business in March over the corresponding month of last year. They have recently completed additions to their works, which are now fully occupied in turning out such quantities of goods as their increased facilities allow. They report a very large increase of business in their "Acme" link belt in particular,—a belt specially adapted to fast-running machines like dynamos. Their trade in the Northwest is largely extended by means of the recent opening of their store in Chicago—165 Lake street—under the management of F. F. Wormer. Among the large shipments of belting made during the past month, are, one to Portland, Ore., and another to San Francisco, Cal.

"MAGNOLIA" ANTI-FRICTION METAL.

The Magnolia Anti-Friction Metal Co., 74 Cortlandt street, New York city, have issued photographs of some journal bearings tested recently, showing the superiority of the Magnolia metal. These tests were made by Dr. H. G. Torrey, a member of the American Society of Mechanical Engineers, and the well-known assayer to the United States Mint of this city. Mr. Corliss, builder of the famous Corliss engine, in his work on friction, gives 2,000 feet as the limit of velocity of rubbing surface per minute in machinery; and, as shown on the photograph, this limit was attained in the test of Magnolia metal and under the enormous pressure of 1,425 pounds to the square inch. These two limits have rarely, if ever, been attained before in practical mechanics.

THE RIVER AND RAIL ELECTRIC COMPANY.

It is stated that this company will probably purchase the factory of the Taylor Hardware Company at New Britain, Conn., and establish a large manufacturing plant there. The company's New York offices are at 45 Broadway. Mr. G. L. Wright is the manager.

THE BALL ELECTRIC LIGHT CO.

The above company will remove their offices on May 1 from 18 Cortlandt street to 404 West 27th street, this city. They report a steady business and a good outlook.

THE NEW WESTINGHOUSE LIGHTNING ARRESTER.

The new Westinghouse lightning arrester which we illustrated in a recent issue is attracting considerable attention among electricians. Besides its simplicity of construction and certainty of operation it possesses the additional advantage that its construction embodies no coils of wire or magnets whatever, thus offering no impedance to the passage of the lightning charge, due to the high self-induction which takes place when electro magnets are in circuit. Our attention has been called to the fact that the new arrester is the joint invention of Messrs. Paul Winsor and Alexander Wurts of the Westinghouse Company.

SCHIEREN "ELECTRIC" LEATHER BELTS.

Chas. A. Schieren & Co. have just received an order from the Citizens' Electric Illuminating Co. of Brooklyn, N. Y., for $98\frac{3}{12}$ feet of 42″ three-ply "Electric" leather belting. They previously sold this company:

106 feet, 42″ Double Elctric Belting,
98 " 42″ " " "
115 " 36″ " " "
115 " 36″ " " "
89 " 36″ " " "
89 " 36″ " " "
115 " 36″ " " "

for "main drive" and all the necessary dynamo belts in addition to this. They have also furnished the Municipal Electric Lighting Co. of Brooklyn with:

$109\frac{7}{12}$ feet, 48″ Double Electric Belting,
113 " 48″ " " "
$93\frac{3}{12}$ " 20″ " " "

for main driving belts, and about 325 of 8″ double electric belting to run their dynamos.

OKONITE.

That Okonite insulated wire will stand a large amount of rough treatment without impairing its utility has been a point always claimed by the manufacturers. Corroborative testimony in a matter of this kind is always acceptable, and those who may have had any doubts regarding the durability and thorough insulation of wire covered with this famous insulating material when used under adverse circumstances, should read carefully Foree Bain's acknowledgement of its good qualities, printed in our pages this issue.

THE CONTINENTAL TELEPHONE CO.

The above company organized in 1879 to exploit the "Bell" telephone, "Blake" transmitter, and kindred telephonic devices in South America, Central America and West Indies, have just voted a final dividend of $10 per share to their stockholders, to be paid on the 26th inst. to those who own, present and surrender their certificates. The Tropical American Telephone Co., L'td., is the successor of this company in the territory above named.

NEW ENGLAND TRADE NOTES.

Pettingell, Andrews & Co. have now got thoroughly settled down in their enlarged quarters, and have now the largest floor space of any electric supply house in the country. All the goods are exhibited on one floor, and with the two new young partners, Messrs. D. A. Andrews, Jr., and C. W. Price, to attend to customers, it makes a most convenient and pleasant store to do business in. Besides their large stock of cut-outs, switches, fuse boxes, etc., Messrs. Pettingell, Andrews & Co. are now making a specialty of carrying a large stock of wires, and have Okonite, P. & B., American Weatherproof and Underwriters, constantly on hand.

Mr. L. H. Rogers, who has made himself most favorably known throughout New England as agent for the Brush Electric Co., has just been appointed agent also for the Short Electric Railway Co., of Cleveland, O. Mr. Rogers reports that the new type of motor has been adopted by Tom and A. L. Johnson, the electric railway magnates of Cleveland, and that the Short company has recently closed the largest contract for an electric railway ever given out, namely, the contract for an electric railway at Rochester, N. Y., which includes 55 miles of track, 200 motor cars, and a complete generating apparatus of from twelve to fifteen hundred horse power. Mr. Rogers intends in the near future to make an onslaught on the railway business of New England.

The Simplex Electrical Co. have got out a new price list and catalogue of their various wires, which is considerably above the ordinary average. In it are contained many valuable tables and formulæ, and a complete treatise on the calculation of wires for safe carrying capacity. The book is valuable to every practical wireman and electrical engineer, and should be procured at once.

The Electric Safety Co. has opened an office at 146 Franklin street, Boston, with Mr. J. H. Coombs as manager, and Mr. D. J. Cartright as electrician, for the purpose of selling apparatus for the protection of electric circuits and instruments, from heavy currents and lightning. They will push especially the Cartright protector, which was warmly endorsed recently by the Boston Fire Underwriters' Union, as being a perfect protector for all kinds of electric circuits.

The New England Safety Co. has opened an office at 146 Franklin street, with Mr. E. E. Zimmerman as manager, for the sale of the well-known Crandall protector. At the recent tests made by the Boston Fire Underwriters' Union this instrument received very warm commendation, and it is already extensively used by the Chesapeake and Potomac Telephone Co., some 8,000 of the instruments being in use by this company. It has also very recently received the warm endorsement of the Department of Public Safety (Bureau of Electricity) in Pittsburgh.

The Boston Electric Club held its monthly dinner at the Quincy House, on Monday evening the 14th inst. at which there were about 60 members present, President Cram being in the chair. Mr. Joseph Wetzler, editor of The Electrical Engineer read an interesting paper (reported elsewhere) on "Electric Railway Evolution," and illustrated the lecture by numerous stereopticon views. Afterwards Mr. Monks, general manager of the West End Street Railway Co. and Mr. George W. Mansfield of the Thomson-Houston Electric Co., made interesting remarks relating to the subject, and a vast amount of useful information was derived.

By the courtesy of Mr. C. F. Hutchinson, general superintendent of the New England Printing Telegraph Co., and Mr. R. D. Wilson, the writer had the pleasure of sending an immediate message this week to one of the representatives of The Electrical Engineer, in New York, which required an immediate answer. From his experience he can cheerfully commend the working of the Essick printing telegraph as to accuracy and speed in every detail, and predicts a large and profitable field for it in the immediate future.

The Westinghouse Electric Street Railway Co. is the latest development in electric street railway work. This organization is now in the field ready for business, and already has some large contracts in hand. Messrs. H. McL. Harding, J. L. Barclay and C. C. Warren, gentlemen well and widely known in electrical circles, are connected with the company and will handle the selling department. With such well-tried talent, business will undoubtedly pour in.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

Vol. IX. NEW YORK, APRIL 30, 1890. No. 104

Nothing is so good as an experiment which, while it sets an error right, gives as a reward for our humility in being reproved, an absolute advancement in knowledge.—Faraday,

LOSS BY HYSTERESIS.

THE communication by Professor Elihu Thomson in our columns this week in reply to thatof Mr. Nikola Teslaon the loss due to hysteresis in transformers is well worthy of careful study, as it embodies an expression of opinion on a subject which is of foremost interest at the present time. Leaving out of consideration the purely controversial part of Professor Thomson's letter, it will be found to give his views on the probable origin of the heat generated by a change in magnetism, independent of the Foucault currents generated thereby. Professor Thomson uses a beautiful analogy to explain the difference in the heat generated by the current in various conducting bodies and that generated in distorting them mechanically; the heat in both cases depending upon whether the ether strain can be transmitted from molecule to molecule without much disturbance of their positions, or without causing a swinging-out of position back and forth. The subject is one that offers wide scope for speculation, and we shall probably find many theories advanced before the light of actual facts is thrown on the true explanation of the phenomena of hysteresis.

PRICES FOR CITY LIGHTS.

It is difficult to believe that the city authorities can be serious in their suggestion that unless the electric light companies reduce their bids, a return may be made to gas for the streets. One of the grounds of complaint is that the companies have entered into a combination to prevent competition. Another is that the prices average 15 per cent. higher than last year. An obvious reply in the first instance is that while there is no combination, there may well be an agreement not to do business at a loss. The prices are generally in the neighborhood of from 39 to 42 cents, and everybody knows that those rates are fair and reasonable, especially in view of the enhanced cost still attending operation in the subway districts.

What may be at the bottom of all this attack we do not pretend to know, but we do not hesitate to characterize it as a disgrace and a shame.

ELECTRIC TRACTION AND THE STORAGE BATTERY.

One of the most important events in electrical matters to-day is the formation of the United Electric Traction Co., with a capital stock of not less than $7,000,000. This company is a consolidation of the Daft and Julien companies, each of which is well known in its respective field of work and has done much to bring electric traction up to the position that it now occupies so commandingly in the industrial and financial world.

Momentous results are, in our opinion, to be expected from this massing of forces, and not the least of these will be a sudden and lasting activity in storage battery traction. The rapid increase in electric railway work in this country during the past two years has been almost wholly due to the use of methods involving the direct supply of current to the cars. In fact, the proportion of roads operating by any other system than that of the trolley and overhead wire is quite insignificant. Various reasons account for the lack of storage battery roads, and one of the gravest has been the uncertainty and weary delay always attendant upon patent litigation. The faith of those who believe in the future of storage traction and who have chafed at the slowness of its general adoption, is however, likely to receive an early encouragement in the new state of affairs. The Julien Company carries with it, we believe, its option on the Brush patent so recently adjudicated upon, and the Daft Company is able to supply everything needed for the equipment of a road. The Daft Company has also, of course, its familiar systems for direct operation.

It seems not at all impossible that this consolidation may lead to other notable changes, but be that as it may, it is important enough in itself to deserve more than passing comment. There are a great many places where the introduction of electric traction without storage batteries is attended with difficulties practically insuperable, and it is sincerely to be hoped that the way may now be made clear for an extension of work in New York; so that the whole city may enjoy the luxurious travel that has been the privilege for a while of the people along the line or in the vicinity of Fourth avenue. The time is ripe for electric traction in New York.

SECTION 4,887.

It has been rumored in Washington that the House Committee on Patents is likely to recommend the unconditional repeal of the last clause of Sec. 4,887, of the Revised Statutes, which makes the term of a domestic patent depend upon that of the prior foreign patent having the shortest term. The removal of the vexatious limitation, with its attendant uncertainties touching the validity of many patents, is much to be desired, not less in the interest of the public than in that of inventors and of the owners of property in patents. But it would, we think, be a grave mistake not to except from the provisions of the repeal patents which may hereafter be issued on applications which shall have been pending at the time of passage of the act. It is well known that applications are in existence covering important inventions which have been in the Patent Office for many years. The corresponding foreign patents have expired, and the inventions have gone into extensive public use on the faith of the provisions of the existing law. If the repeal be made unconditional, the owners of these pending cases may be able to put several important industries under a seventeen years' tribute, which would be, to say the least, most unfortunate. It is to be hoped that this consideration will be strongly urged upon the attention of Congress, when the matter comes up for action.

The Late Charles W. Jenks.

THERE will be found in our pages this week an obituary sketch of the late Charles W. Jenks, who was distinctively a pioneer in more than one department of electrical application, and who at the time of his death was busily engaged introducing the electric motor for mining purposes. Mr. Jenks was typically American in his readiness and versatility, his resilience under the pressure of adverse circumstances, his buoyancy of hope and courage, and, above all, in his generous spontaneity of sympathy and active goodwill. We held it an honor to enjoy his friendship and esteem, and are glad to add a modest tribute to his memory.

Comfort In Hotels.

A LEGAL decision in Tennessee holds that a guest cannot be charged for a fire in his room, the hotel having tacitly agreed to make him comfortable when it opened its doors for business. The incident is not without suggestion. It stands to reason that the hotel giving its guests the greatest number of comforts and conveniences will draw the largest custom. On this principle the hotel with electric lights, electric annunciators, bells, etc., will be more attractive than another without them. We believe, for example, that any hotel in our cities, during the summer time, putting in electric motor fan outfits and advertising "bedrooms cooled all night by electric fans" will through that very innovation secure an enormous share of patronage. Have our motor friends tried to work up such a business?

Exhibitions as Educators.

IT will be remembered by those of our readers who had anything to do with the Electrical Exhibition at Philadelphia in 1884, that the Franklin Institute, through Mr. G. M. Eldridge, secured the attendance of a large number of school children, the official record showing the formal visits of no fewer than 97 schools, 740 teachers and 16,657 students. Great good was done by this use of the Exhibition in an educational way, and we venture to suggest to the management of the Women's Exchange Electrical Exhibition in this city that they could develop the idea now to their own advantage and to the decided benefit of the school children of New York. A better "object lesson" for young inquiring minds could not be found than the telephonic, phonographic, lighting and power exhibits and experiments at the Lenox, illustrating the various arts as they exist most perfectly at the present time.

The Foe of Thief, Moth and Worm.

REFERENCE was made in our columns recently to an invention that proposes to destroy insects by luring them against a charged cage within which is an intense electric lamp, the shock from the bars killing them. The *Manufacturers' Record* quotes our article in full, and in its editorial comment makes the interesting statement that at Durham, N. C., since the city has had electric illumination, the ravages of the tobacco worm have been greatly reduced. It suggests that a powerful electric light in the centre of one of the sea islands growing the famous long staple cotton might save all the plantations surrounding it from the destruction so frequently wrought by the cotton army worm. The idea is ingenious, and it seems to us that such lights would also be very useful during the ingathering of the crop.

Honoring with Official Abuse.

FOR some reason best known to himself, Mayor Grant takes special pleasure in girding at Dr. Wheeler, the efficient and zealous electrical expert of the Subway Board, whenever a chance can be secured. Last week he seized an opportunity to scold, and made the most of it, some of the papers following his lead. Possibly the feeling is of a personal nature, but that is hardly likely, since Dr. Wheeler is not a politician with a pet Christian name, and, on the other hand, it is well known that the Mayor's educational qualifications are not such as to bring him in competition with Dr. Wheeler on professional grounds. It is a great pity and evil that engineers and other trained men in the city's service should be exposed to this sort of thing in the discharge of their duty. We advise Dr. Wheeler, however, to maintain his equanimity and to leave the Mayor to Time and the Investigating Committees.

Hopkinson on Magnetism.

IN this issue we bring to a close Dr. Hopkinson's admirable résumé of the present state of our knowledge regarding magnetism. The phenomena of recalescence and the peculiar behavior of the alloys of nickel, manganese, cobalt and iron have recently opened up a new field for investigation, and this paper of his will assist towards arriving at a more comprehensive theory of magnetism than has yet been advanced.

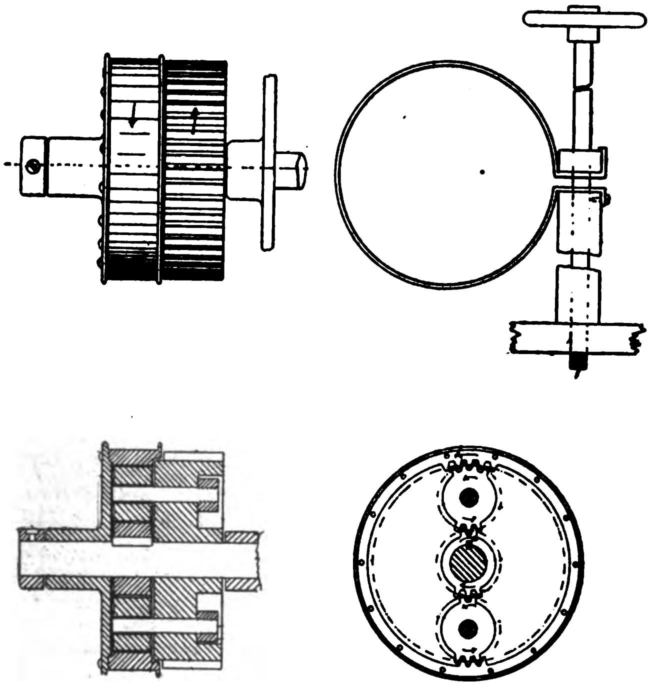
Growth of Light and Power Interests.

THE annual report of the Thomson-Houston Electric Company, given in our columns to-day, shows that the company had at the beginning of the year a clientage of 587 local companies using its arc and incandescent systems. The list we give of electric railway companies operating under the Sprague system shows a total of no fewer than 1,228 motor cars. A comparative statement from Pittsburgh shows that if the business of the year is maintained at the present rate, the sales of the Westinghouse company will aggregate $7,500,000 as compared with $4,500,000 in 1889. And yet these are but a few of the figures that could be cited to prove the enormous development of electrical industries at the present time.

HENRY'S ELECTRIC CAR GEAR.

In a recent issue we had occasion to point out the fact that the frequent starting and stopping of the motors on electric cars was a source of considerable loss as well as a strain on the motor. We illustrated at that time a device of Mr. J. C. Henry to avoid these objections, but are enabled this week to describe the apparatus actually employed by him in his roads at Kansas City and San Diego, several years ago.

The motor gearing, or rather the connection between the motor and the car axle is shown in the accompanying engravings, Figs. 1, 2, 3 and 4. It consists of a pinion keyed to the motor shaft, is surrounded by an internal gear loosely mounted on the same shaft, and intermediate pinions engaging with both of them. The intermediate pinions are loosely mounted on pins which in turn drive an external gear, engaging with one on the car axle



Figs. 1, 2, 3 and 4.—Henry's Electric Car Gear.

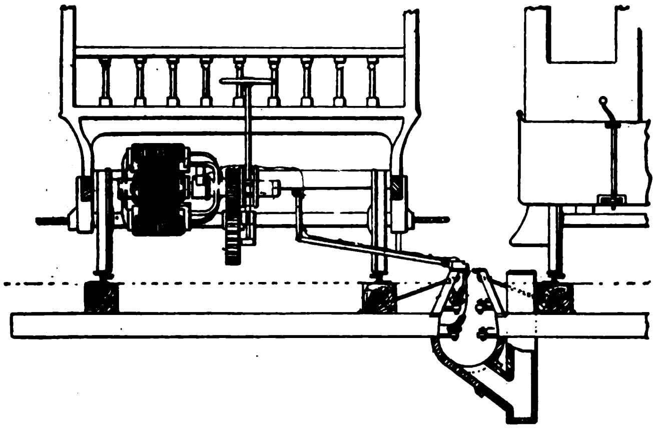


Fig. 5.—Henry's Electric Railway Conduit.

The armature runs constantly, and when the car is standing the armature and internal gear are revolving freely. As the internal gear is retarded by the clutch, the car moves, gradually increasing its speed until the maximum is reached. In this case the internal gear is held stationary. In order to stop the car the clutch is released; this disconnects the armature and, at the same time, the continued movement applies the car brakes. In practice, wooden shoes are used on the clutch and they are kept lubricated. By allowing the clutch to slip, a strong yielding leverage can be had to start heavy loads or climb heavy grades, as demonstrated during four years' use of this device by Mr. Henry.

The main object of the arrangement, as remarked above, is to prevent abnormal currents in the motor and to avoid breaking the circuit. By the employment of an internal gear, strength and compactness are obtained and it permits the speed-reducing parts to work in an oil bath perfectly free from dust. The advantages of this are apparent.

It will be noticed that the movement is a differential one. With pinions of the same diameter, the intermediate gears make a single planetary turn to four complete turns of the central gear.

The engravings, Figs. 5 and 6, show a sectional view of the construction of the Henry conduit, the main electrical features of which are the location of the separate conductors, the return conductors being placed below. It may thus be covered with water without detriment to the operation of the road. The conductors are supported from oil cup insulators, and the traveling contacts are springs which grasp and cling to the conductors. It will also be noticed that but a single conduit and slot are employed for a double-track road.

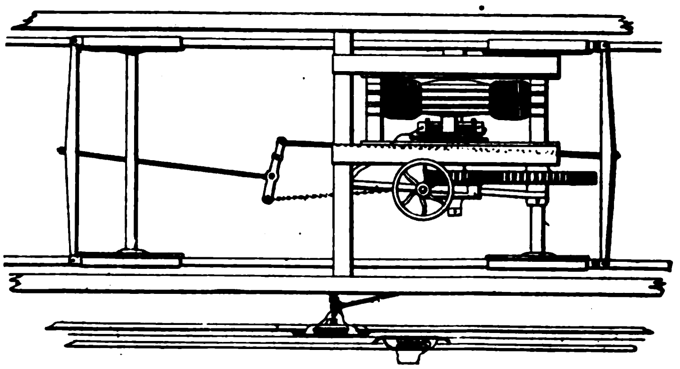

Fig. 6.—Henry's Electric Railway Conduit.

EPSTEIN'S SECONDARY BATTERY PLATES.

There are still a number of inventors at work on the storage battery who are devoting their attention to the perfection of a plate not provided with the active material mechanically applied, but in which it is formed upon the plate by chemical and electrical means. Among those who have in the past followed this method is Herr Ludwig Epstein, of Berlin, Germany, who has recently brought out a process of plate formation for both positives and negatives, which embodies several novel features, and the object of which is to obtain a quick formation without loss in capacity or durability of the plate.

This object is obtained by dividing the process of manufacturing the electrodes into two separate parts, the first part being limited to the making of so-called "raw" electrodes, which latter are then transformed into positive electrodes with the assistance of the electric current in an electrolyte containing either diluted sulphuric acid or a suitable compound of sulphuric acid, while the negative electrodes are formed by a reduction of the positive electrodes. In order to obtain the so-called "raw" electrodes that furnish the raw material for the final electrodes, bodies consisting of lead of any shape whatever and suitable for use as electrodes are put into water rendered acidulated by the addition of a small quantity (about one per cent.) of nitric acid, and then this water is heated up to the boiling-point. The lead bodies immersed in water of this kind are kept from coming in contact with each other by being suspended in such a manner that the fluid has access to them all around. The water is always kept up to the boiling-point, and the boiling is continued till the metallic "glance" that the lead bodies originally had has disappeared and the lead has assumed a dull gray appearance. The lead bodies thus treated are then taken out of the boiling water and dried in the air.

By this action there is produced on the lead bodies a grayish yellow deposit of lead compounds which is fine grained in structure and has the appearance of mildew.

This deposit adheres very firmly and is insoluble in the electrolyte used for the subsequent treatment in dilute sulphuric acid. In addition it has a great capacity for taking up the gases engendered in the formation process, so that the latter may proceed quickly, without the necessity of reversing the current. It is these "raw" plates as they are called from which the positives as well as the negatives are formed.

In order to form positive electrodes, a number of raw electrodes forming a group are put into the electrolyte, lead plates being inserted between them; or they are put in together with positive electrodes that have to be transformed into negative electrodes. The raw electrodes that have to be formed into positive electrodes are then connected with the positive pole of the primary current and the intervening plates with the negative pole of the primary current, by which means the formation of the electrodes by the effect of the electrolyte commences as soon as the current is turned on. In this process of forming positive electrodes the former grayish-yellow color of the raw electrodes changes into a deep dark-brown, almost bluish-black hue, and the process is completed as soon as the electrodes have assumed that color, and an abundant development of gas (oxygen in this case) takes place on the positive electrodes thus formed.

For the purpose of forming negative electrodes part of the lead bodies converted into positive electrodes by the process just described are used in the place of the lead plates inserted between the electrodes formed into groups, as above mentioned, in the formation of positive electrodes.

The oxygen of the peroxide of lead produced on the positive electrodes which are to be reduced is absorbed by the effect of the electric current and the bodies are reduced on their surface to porous metallic lead. The process of forming negative electrodes is finished when the deep dark-brown or bluish-black color of the positive electrodes used for the purpose has changed into a bluish-gray hue and an abundant development of gas (in this case hydrogen gas) takes place on the negative electrodes thus formed.

The advantage in favor of the method just described is in particular that for forming electrodes of one sort from the raw electrodes prepared in the way described, a few hours only are necessary, and the reversing of the electric current used in other processes for this operation is unnecessary, so that in a very short space of time a great number of positive as well as of negative electrodes can be produced. Further advantages are also claimed in that these electrodes last extremely well, and that even in case of frequent heavy charging and discharging there is no scaling. They are claimed also to afford a far greater storage capacity, weight for weight, than the types of plate in general use.

THE EDELKAMP THERMO-ELECTRIC BATTERY.

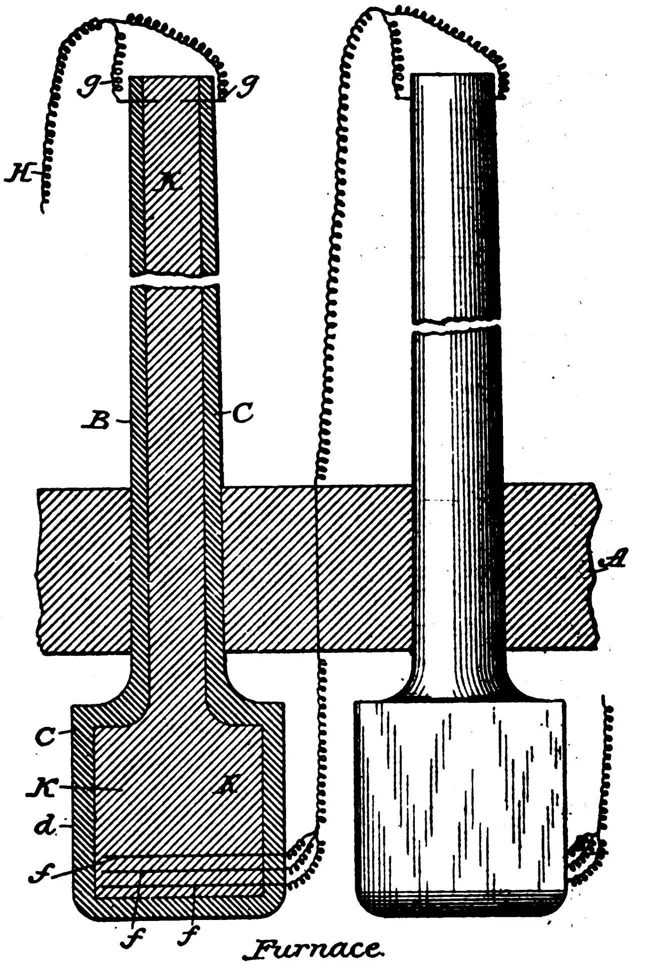
One of the obstacles encountered in generating electricity by means of heat is found in the frailty and instability of the elements necessary in the construction of a thermal battery and in the destruction incident to their exposure to the high temperature of the furnace.

To avoid this difficulty Mr. John Edelkamp, of this city, has devised an arrangement in which that part of the element exposed to the action of the heat is protected. The result of this is that the thermo-element, it is claimed, can be exposed to much higher heat than has heretofore been deemed desirable.

This improvement has been carried out in the manner illustrated in the accompanying engraving, which shows two elements in perspective and in sectional view respectively.

The elements B B, it will be noted, are supported in the wall so that one end of each is fully exposed to the heat of the furnace and the opposite end is left projecting outward to such a distance as will permit it to be kept comparatively cool by extraneous influences.

The elements are each constructed of an outer casing C, of fire-clay and have an enlarged base *d*, rectangular in form, and an extended cylindrical neck projecting centrally from one side, as shown in the engraving. Through the walls of this casing, near the opposite extreme ends, a series of electrode-wires *f f f* and *g g* are inserted, from opposite sides, which project nearly to the centre of the casing; the several wires thus projecting through the wall into the casing are united at each end and connected to the single conducting-wires H, by which the circuit is completed. These electrode and conducting-wires are made either of copper or of an alloy of nickel and copper.



Edelkamp's Thermo-Electric Battery.

The interior of the casing C is completely filled to its extreme outer end with an alloy K, of antimony and zinc, to which cadmium has been added.

It will be noted that only one alloy is employed for the generation of current, the difference of temperature between the two extremities of the piece being depended upon for the development of the difference of potential. The cool outer extremities of each element, is the positive and the heated end the negative pole.

. . . I think the secret of illumination by incandescent electric light is the fact of the distribution of that light. It is hung around in different parts of the room and distributed thoroughly. The light from a chandelier emanates from one point, and the walls of a room, and every place where you look for the effect don't seem to have the light cast equally; at the chandelier there is an excess of light.—*C. H. Evans.*

AN ELECTRIC WIRE COVERING MACHINE.

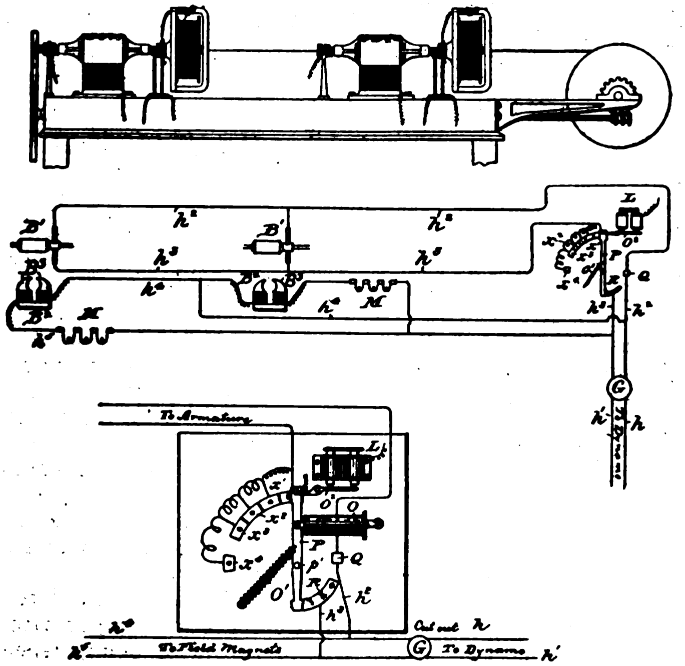
The wonderful adaptability of the electric motor for the direct application of power without the use of intermediate gearing is being recognized more and more every day, with the result that hardly a week passes but some old form of machine is being remodeled to take advantage of this fact. Among the recent applications of this nature is a wire covering machine, the invention of Messrs. Frank E. Davis, of Boston, and John Scott, Jr., of Plymouth, Mass., a general view of which is shown in the accompanying engraving, Fig. 1. The winder, as will be seen, consists of two covering heads and a feed drum. Both winding heads are driven direct by motors, and provision is made for the immediate stopping of the machines on the breaking of the current thread, by the rupture of the current.

In order to secure an even winding of the covering it is, of course, necessary that both winding heads should run at exactly the same speed, and to effect this a special arrangement of circuits and connections has been adopted, which will be understood by a reference to Fig. 2.

As shown, the field magnets of the two motors are arranged in multiple arc, and the current is carried to both armatures of the motors by the circuit h^2 h^3, which is separate from the field magnet circuit.

By arranging both the armatures in the same circuit their rotation at the same speed is secured. If one armature tends to run faster than the other, the first will become practically a generator to the second and supply it with current to accelerate its speed, at the same time the extra effort exhausting its tendency to run faster.

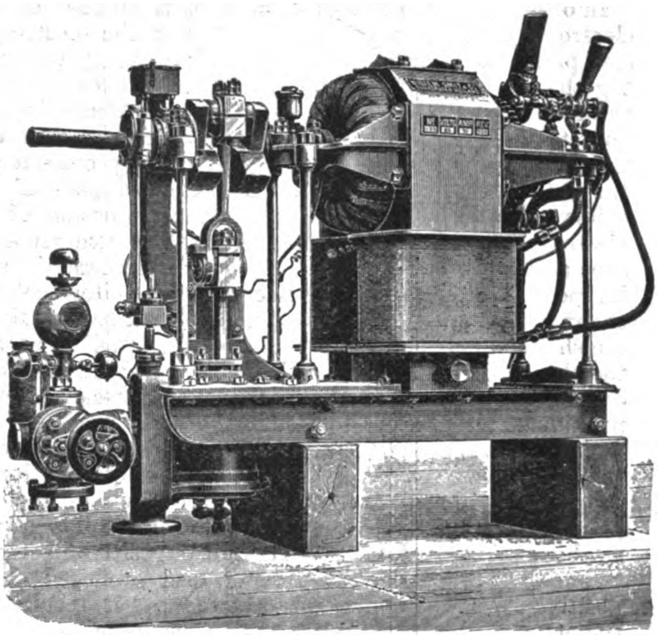
For the purpose of stopping the machines on the breaking of a thread the device shown in Fig. 3 is employed. In this, the upper end of the switch-lever P, when released electrically by the rupture of the thread, is thrown by the spring O′ toward the left, bringing its end successively in contact with the contact-blocks of the resistances x' x^2 x^3, its lower end remaining in contact with the arc R. The effect of this movement is gradually to increase the resistance of the armature-circuit, and thereby reduce the speed of the motor. The further movement of the switch-lever P moves the upper end of the lever off the contact-blocks of the resistance x^3, and at the same time moves the lower end of the lever off the arc R, thus breaking the circuit. The final movement of lever P brings its upper end onto the contact-block of resistance x^4, and at the same time brings its lower end onto the contact-block Q, and closes the armature-circuit on the resistances x' x^2 x^3 x^4. It will thus be evident that the action of the switch-lever when released is to successively insert resistances in the armature-circuit, break the circuit, and short-circuit the armatures on resistance.



Figs. 1, 2 and 3.—A New Electric Wire Covering Machine.

THE SMIT COMBINED ENGINE AND DYNAMO.[1]

Messrs. Smit, of Slikkerveer, Holland, have brought out a neat combination engine and dynamo lighting an arc light projector at sea. It is designed with a view of having as little weight as possible. The output is 65 volts and 70 amperes, as required for the Dutch Navy's torpedo boat "Cerberus." In order to reduce the weight to the lowest possible limit, as demanded by the naval authorities, Messrs. Smit have used an open engine instead of the closed-in type, and thus have decreased efficiency, durability, and freedom from breakdown. The armature is Gramme wound with 3.5 mm. wire. The speed is 450 revolutions per minute, and is controlled by an electromagnetic governor interposed in the shunt circuit.



The Smit Combined Engine and Dynamo.

The engine has 4 in. cylinder, by 5 in. stroke, and works with 100 lb. to 150 lb. pressure of steam. The engine and dynamo together weigh 840 lb., and the 20 in. projector to match weighs 520 lb., or 1,360 lb., total weight. The outside dimensions are 3 ft. 9 in. long, 2 ft. 6in. high, and 1 ft. 5½ in. broad.

THE STEPANOFF ELECTRIC BLEACHING PROCESS.

In the method of electric bleaching devised by M. Stepanoff, common sea salt is employed instead of chloride of magnesium, as in the Hermite process. A solution of sea salt is pumped into an "electrolyser," having lead and platinum electrodes, and is there submitted to electrolytic action; after which, the electrolysed solution is pumped into the bleaching tanks. With his present apparatus M. Stepanoff uses 40 amperes and 45 volts, and is able to furnish 300 litres (66 gallons) of chloruretted solution per hour. Although matters may be so arranged that a 1 6 per cent. solution can be obtained, M. Stepanoff does not, as a rule, employ a solution containing more than seven per cent. of chlorine. The substitution of lead for zinc electrodes in the electrolysers is claimed as an improvement.

... There are endless patterns of dynamos in the market, but all those of the best makers give approximately the same efficiency and possess the same qualities generally.—*Sir D. Salomons.*

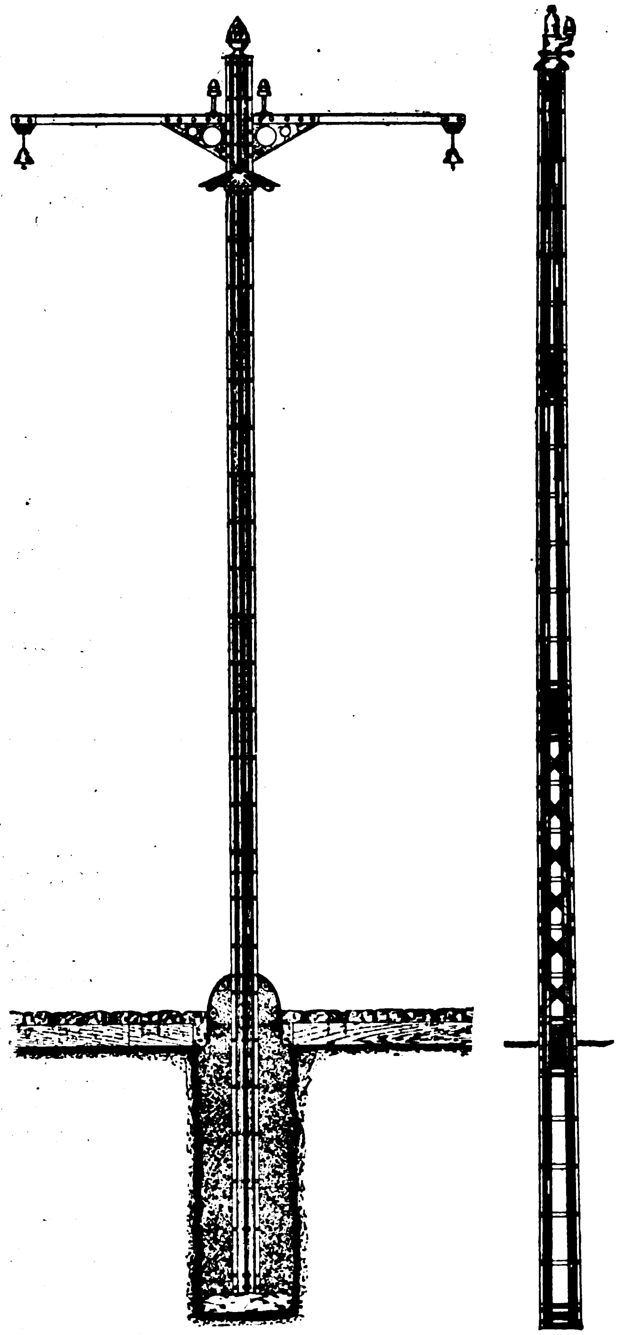
[1] *Industries.*

THE MILLIKEN ELECTRIC RAILWAY POLE.

The overhead system of operating electric railways has made such rapid strides and presents such unquestionable advantages, that it is fair to assume that it will for a long time continue to be the standard method of conducting the current to electric street cars. One of the most important elements entering into the maintenance of the integrity of the overhead construction, is the pole from which the wires are suspended, either directly, or by span wires; and past experience has shown that lack of strength and proper methods of erection soon lead to irregularity in the lining of the conductor with consequent ill effect upon the running of the trolley. To this is added an unsightly appearance of the line which frequently gives rise to complaints.



Figs. 1 and 3.— The Milliken Electric Railway Pole.

To remove these objections, iron poles have been largely employed in place of the wooden ones, and with marked success. Heretofore, solid iron poles have been generally used, but an interesting departure in this direction has recently been brought out in the shape of an open wrought iron pole, for which a number of advantages are claimed.

The Milliken pole, as it is called, which is now being introduced by Mr. Lemuel W. Serrell, of this city, is formed of four sections of iron of the "Phœnix" shape, riveted together with tie plates, placed equidistant, with latticework inserted at the point of greatest strain. This is clearly shown in the accompanying engravings, Figs. 1 and 2, which show respectively an elevation and transverse section of the centre-pole type adapted for double track roads. As will be seen, a taper is given in the direction of greatest strain, making a pole having the greatest possible strength for the weight of material used. These poles are very light and durable, and, being open, present a very pleasing appearance to the eye, while the inside can be painted and preserved indefinitely from the action of the air.

This type of pole was recently tested at Post & McCord's Bridge Works in Brooklyn, and the pull at the top measured by a Fairbanks dynamometer; with a pull of 800 lbs., the deflection was less than four inches. The deflection took place in a regular curve, and showed no irregular bending at any point. A block and tackle was then attached at the upper end of the pole and the building, and eight men pulled on the rope; unfortunately, the concrete was not quite dry, and the pole moved bodily in the earth, the top being moved some six feet towards the building, breaking the concrete up in lumps. When taken out of the ground the permanent set was so small that the pole was readily straightened in jaws.

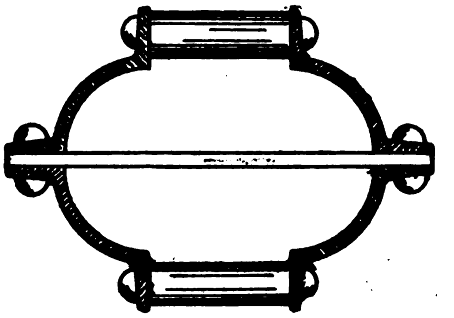


Fig. 2.—Transverse Section of Pole.

The centre-pole for use between the tracks has its longest diameter parallel with the rails, and, when arranged with an ornamental top and lamps, makes a very artistic pole. The cross-arms can be made separate from the pole, if so desired, for shipment, and bolted on after it is set in the ground. A cast iron bumper to keep wagon wheels from striking the pole is also provided at the bottom. This is made in two parts, bolted together on the inside, and can be filled with concrete, as shown in the engraving.

At present a number of these poles are being made for the Jersey City and Bergen Railway Co., who recently contracted for the equipment of their lines with the Thomson-Houston system.

The engraving, Fig. 3, shows the same style of construction as employed in the pole to be used in connection with span wires.

PROTECTION OF SUBMARINE CABLES.

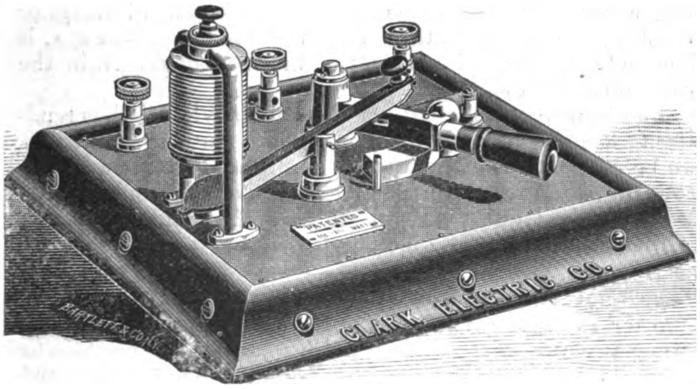
The text of the convention for the protection of submarine cables, held in Paris, has just been published as a parliamentary paper. It is a punishable offence to willfully damage a cable to the interruption of telegraphic communications; but this clause (No. 2) does not apply to those who injure it with the object of saving life or their ship. If the owner of a cable damages another one he must repair it, and that without prejudicing a penal action which may be instituted. It is compulsory for all vessels and fishing boats to keep a mile away from any ship engaged in laying a cable. Owners of vessels who can prove that they have sacrificed gearing or anchors in order not to injure cables can recover the amount from the owner of the cable if applying at once. The treaty, which is an international one, and applies to the colonies, remains in force for five years, and is to be renewed yearly.

THE CLARK AUTOMATIC SAFETY DEVICE.

In operating series-wound dynamos, if the line-wire is broken by accident or design, the flow of current being interrupted, the electromotive force falls to a greater or less degree, depending upon the power of the dynamo, and the residual magnetism of its field-magnet cores. The electromotive force which still exists, however, may be sufficient in the case of large dynamos to give dangerous shocks to persons or animals that may accidentally come in contact with the broken wires. Should the broken wires, in falling, make contact with any other good conductor—such as another wire, an awning-frame, or metallic roof—this conductor becomes part of the circuit, which, being thus completed, permits the dynamo at once to resume its action, rendering the accidental portion of the circuit dangerous to persons coming in contact with it, as well as being liable to cause fires by reason of the faulty nature of the contacts with the broken ends of wire. Another danger from such an accident is to the dynamo itself. At the moment of interruption of the current, the lamps or motors in circuit at once assume their condition of lowest resistance. If, then, the circuit is suddenly closed, the dynamo resumes its action instantly, and the result is an abnormal rush of current, which may injure the dynamo. This is particularly the case if an automatic regulator is used with the machine. Such regulators operate, as a rule, to maintain a constant current through a variable resistance; when, as in case of a broken line, the resistance becomes very great or infinite, the regulator in the effort to maintain the current at once applies the greatest electromotive force the machine can produce, thus increasing the dangers from the broken wires.

To obviate all these elements of danger in connection with high tension circuits, Mr. E. P. Clark, electrician of the Clark Electric Co., of this city, has recently patented and brought out a safety device, which has already been mentioned in our columns, and which we are now enabled to illustrate.

The Clark safety device is constructed in various forms to adapt it for series or shunt arc machines, and also for alternating dynamos. Our engraving, Fig. 1, shows the apparatus as designed for series wound arc machines, and the diagrams Figs. 2 and 3, show very clearly the manner in which it acts to render the line safe the instant a break occurs in the circuit.



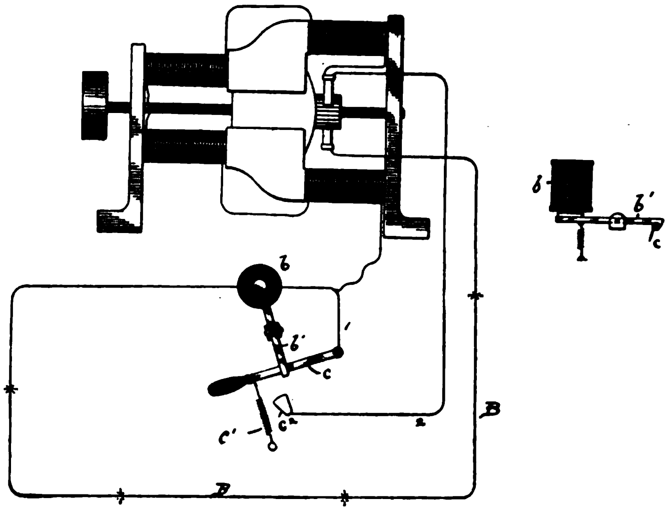
CLARK ELECTRIC CO.

Fig. 1.—The Clark Automatic Safety Device.

As will be seen the small electro magnet *b*, is located in the main circuit, and, as long as the current flows, its armature lever, *b*, is held firmly up, locking the switch in position, and permitting the current to pass to the line. Should the line break or be cut by firemen or others, the current ceases instantly, and the armature of the electro magnet *b* falls, releasing the switch, which flies back under the influence of its spring *c*. The result of this movement of the switch is to close a short circuit, 1, 2, across the field coils of the dynamo, thus depriving them of all current, and of course rendering the dynamo powerless.

The hard rubber knob shown at the top of the magnet in Fig. 1, is attached to a rod reaching through the magnet core, and is used as a convenient means of throwing the dynamo out of action at any time; it being only necessary to force the armature away from the magnet, by a light tap on the knob, to put the machine quickly out of action without any strains or shocks.

Another valuable feature of this device is, that it works automatically every time the dynamo is stopped or put out of action, and it must be re-set by hand, as the last thing to be done when starting the machine on its load. This, in a measure, insures its proper inspection and action, when it is called upon; for should it get damaged or out of order the attention of the person in charge is called to it, as he must operate it every time in starting up.



Figs. 2 and 3.—The Clark Automatic Safety Device.

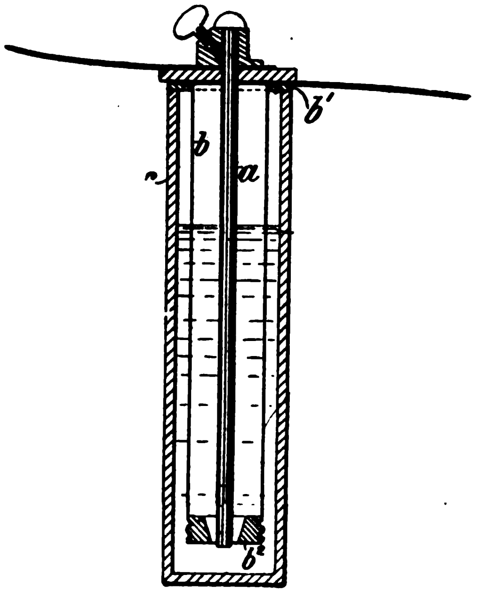
The safety devices for shunt wound dynamos and for alternators vary somewhat from the foregoing description in their electrical details, but the device described above embodies the general plan on which all are constructed; the object in all varieties of the device being to put the machine out of action instantly upon the breaking of the line, and to accomplish this with certainty, and without endangering the machine in any way.

THE RENARD CHLOROCHROMIC BATTERY.

The art of ballooning has in recent years undergone considerable progress due in a large part to the application of the electric motor for the propulsion of balloons, and coincident therewith efforts have constantly been made to provide as powerful a battery as possible combined with the least weight. On account of the latter requirement storage batteries have not been applied for this purpose, but, attention has been given principally to the primary battery. Among those who have devoted considerable time to this work is Major Renard, chief of the Ballooning Department of the French Army, some of whose work in the past at the Meudon station near Paris, may already be known to our readers. The results of Major Renard's work in the production of a light powerful battery, led him to the employment of a battery which has just been patented in this country and which he claims is six times as powerful as the ordinary bichromate cell of the same weight. The improvements made by Major Renard, comprise not only the employment of a new exciting liquid but in addition a novel form of cell.

The solution employed consists of a chlorochromic mixture, obtained by dissolving pure crystallized chromic acid direct in dilute hydrochloric acid. The proportions giving good results are as follows: Hydrochloric acid at 11° Beaumé, 200 cub. centimetres; and pure crystallized chromic acid from 40 to 100 grammes.

The element employed by M. Renard is shown in the accompanying engraving. It consists of a slender zinc pencil *a*, and for the particular purpose for which the battery is designed, the dimensions are so calculated that the zinc is entirely dissolved when the liquid is exhausted, so that each new charge of liquid shall correspond with the renewal of the zinc pencil. This arrangement has for its object to place in the battery only the exact weight of zinc necessary for its working, and consequently to reduce to a minimum the weight and volume.



RENARD'S CHLOROCHROMIC BATTERY.

Another feature of the cell is the employment of a negative electrode *b*, consisting of a sheet of silver covered by lamination on both surfaces with a very thin coating of platinum. There is thus obtained a conductor possessing the conducting power of silver with the inalterability of platinum, the cost of which, moreover, is not much more than if it were made entirely of silver.

The long tubular form of the elements is favorable to the cooling down of the same, which is necessary in this battery, as the activity is very great and the exciting-fluid might attain too high a temperature if the cells did not present a considerable external surface in proportion to their volume.

FIXING IRON FILING CURVES.

In a recent number of *La Lumière Electrique* is described a new method of fixing iron filing-curves, due to M. Korobow. The usual method of fixture, on a plate of glass covered with gum by passing a jet of vapor over the surface, is objected to on account of needless cost and the unsatisfactory nature of the results obtained. The photogaphic method is, moreover, difficult, and only possible to a comparatively few. M. Mach's process consists in mixing iron filings with aniline powder and spreading over the surface. The figure is formed in the usual way, the iron filings are removed by means of a magnet, and the aniline remains fixed to the paper. The figures obtained are, however, seldom sharply defined. In Mr. Korobow's process a plate of glass is warmed on the smooth upper surface of a shallow iron dish containing water raised to a suitable temperature by means of a spirit lamp. A piece of paraffin is placed on the glass, and in the course of three or four minutes spreads itself evenly in a thin layer over the surface The glass plate is removed, the surplus paraffin running off. The image is formed with iron filings on the cooled paraffin, which does not adhere to the iron; so that, if the image is unsatisfactory, the filings may be removed and a new figure taken. To fix the curves the plate of glass is again placed on the warming stove. Finally, the surface of the paraffin is covered with white paint, so that the curves appear black on a white ground. Very well-defined figures may be thus obtained. A similar, though much simpler, process consists in covering one surface of stiff white paper with a layer of paraffin, by warming over an iron plate, spreading the filings over the cooled surface, and fixing them with a hot iron or a gas flame.

THE SEYMOUR UNIVERSAL CARBON HOLDER.

THE constant handling which the carbon holders in an arc lamp are subjected to, together with the wear which the deterioration which they undergo makes their renewal from time to time necessary. To avoid this as far as possible and also with the object of overcoming some of the troubles inherent in this important part of the lamp, Mr. A. P. Seymour, of Syracuse, N. Y., has devised a new form of holder both for the upper and lower carbon. The former, which is illustrated in the accompanying engraving, Fig. 1, is adapted to hold either a $\frac{7}{16}$ or $\frac{1}{2}$ inch carbon, and by providing the slot A the holder can adjust itself to any variation of the screw thread on the carbon rod. The act of clamping the carbon tightens the holder on the rod, preventing all lateral motion of the carbon and also the shaking of the holder from the rod by the wind.

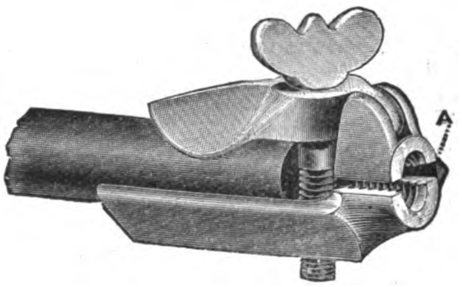


FIG. 1.—SEYMOUR'S ARC CARBON HOLDER.

The holder designed to keep the lower carbon rod in position, is shown in Fig. 2. It holds the carbon firmly with a very slight pressure of the screw A, as the lever B acts like a cam, and tends to wedge the carbon when it drops or is pushed down. The thread of the clamping screw A, is completely protected so that the melted copper from the carbon cannot clog it.

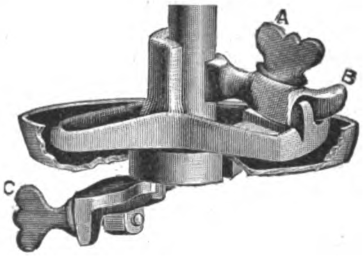

FIG. 2.—SEYMOUR'S ARC CARBON HOLDER.

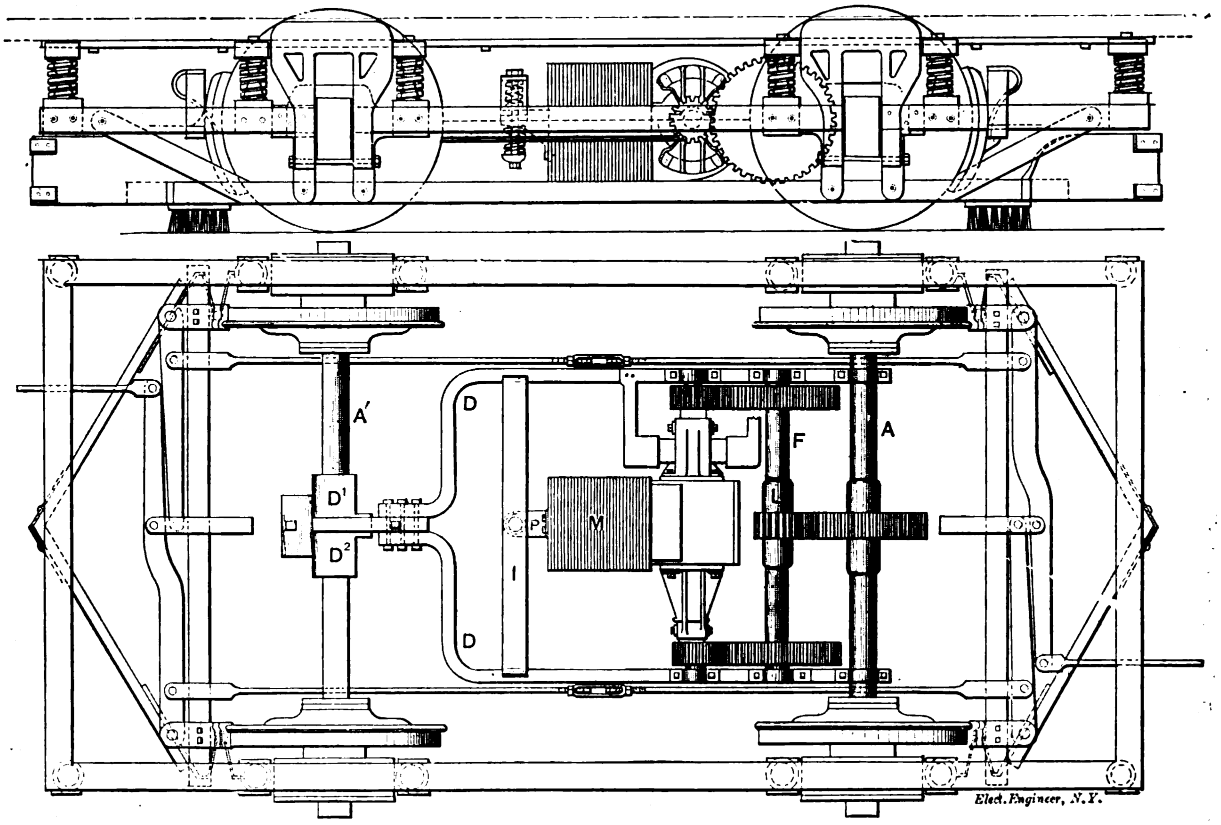
The bearing of the body of the holder is large, thus tending to keep the carbon upright. The adjusting screw C, is on the underside of the dust pan of the lamp, and therefore protected from dust or melted copper from the carbons, and can easily be got at and the holder adjusted without removing the globe.

THE REIGNIER AND BARY DYNAMO.

At the last *séance* of the Société des Électriciens, M. Reignier gave some interesting particulars with regard to the machine he is constructing in conjunction with M. Bary. MM. Reignier and Bary have made a great point of reducing the resistance of the magnetic circuit. By diminishing this they have been able to employ a very small magneto-motive force, and consequently to greatly diminish the weight of copper; and the total weight of machine for a given output is, therefore, at the same time considerably reduced. The method adapted by M. Reignier for reducing the resistance of the air-gap consists in winding the armature with a conductor composed largely of iron. The machine is of the ring type. The armature conductors are composed, and consist of a strip of copper, sandwiched between two strips of iron, and kept together by the insulating covering. But as in a ring the external surface is larger than the internal surface, the strips of iron are only on the outside. The machine, which has actually been constructed, has an output of 10.5 kilowatts (70 volts and 150 amperes) at a peripheral speed of 10 metres per second (33 feet per second), and at an angular velocity of 1,800 revolutions perminute. The machine weighs 263 kilogrammes (580 lbs.) Its output for weight is thus 40 watts per kilogramme (18.2 watts per lb.) The electrical efficiency of the machine is 94 per cent. and the commercial 90 per cent.

THE NEW PECKHAM ELECTRIC CAR TRUCK.

When electric railroading first occupied the attention of electrical engineers their work was in a large measure designed to conform as nearly as possible to the methods of railroad transportation in vogue at that time, and as a result started out with the idea of employing a locomotive having a single motor as the driving power. Later developments, however, saw a change from this type to the electric car in which two motors were employed, each geared to one of the axles. Although this may be said to be the standard car of to-day, signs are not wanting that the near future will develop a decided departure which will in all probability lead to the employment of a single motor to each car, geared to one or both axles, together with various modifications in the style of the truck and attachment of the motor to the axles.



Figs. 1 and 2.—The New Peckham Electric Car Truck.

Mr. Edgar Peckham, of this city, who has given considable attention to this branch of electric railroading, and who has designed numerous improvements which are already well known and in use, has recently brought out an improved electric car truck which presents a number of novel features both of arrangement and construction. Mr. Peckham's object in this new design has been, among others, to secure a flexible connection between the truck frame and the supporting frame of the motor by which torsional strain is prevented when the cars are traveling on a curve, so that the motor and its gearing are relieved from all liability of displacement and consequent injury. At the same time the design is such as to bring the weight of the single motor employed more nearly in the longitudinal centre of the truck, so as to prevent the crowding of the motor proper with its gearing and the counter shaft. This is clearly indicated in the accompanying engravings, Figs. 1 and 2, which represent respectively a plan and elevation of the new Peckham truck.

As will be seen, both ends of the armature shaft are supported in bearings on the motor frame D D, and it is geared near both of its ends to the counter shaft F. This shaft again is geared centrally between the side bars of the motor supporting frame to the axles of the driving wheel A, in contradistinction to the usual method of connection, which is situated at one end only. This construction is claimed to avoid all disarrangement by the vibration of the motor and truck, and also insures regularity of movement with the cars.

The curved supporting frame D D is applied to the beam D^1 which projects forward and is supported on the enlarged surface of the box D^2, which is applied to the axle A^1. The purpose of making the top of the surface of box D^2 of considerable width transversely is to afford a sufficient bearing in the spring end of the beam D^1 when the motor supporting frame D D is being subjected to torsional strain. The box D^2, while fixed to the axle A^1, is flexibly connected to the beam D^1, so that the motor-supporting frame is practically swung on a pivot at its rear end, and can thus assume the vibratory and oscillatory movements of the truck.

It will also be noted that the field magnets of the motor M, are so mounted upon the supporting frame D D, as to bring them practically in the centre of the truck frame longitudinally and transversely. The advantage of this arrangement is that the weight of the motor is more evenly distributed over the truck frame. To effect this arrangement the heel of the magnet is provided with a tail piece P, which is supported at the rear of the armature shaft and on the opposite side of the counter shaft. This tail piece, P, is supported between springs which permit of the magnets yielding vertically. By thus supporting the heel of the magnet in the position shown, the space between the armature shaft and driving wheel A, is not unduly crowded, so that the counter shaft and the various gear wheels can more easily be reached when changes and repairs become necessary.

It will also be noticed that the space gained by this arrangement permits of the enlargement of the counter shaft and driving axle A, at the point where the gears are attached, so that both these shafts are additionally strengthened at the point where the power is applied. The arrangements here adopted are claimed by Mr. Peckham, to overcome a number of disadvantages which exist in the present style of truck in use.

ON THE SPECIFIC RESISTANCE OF METALS AND ALLOYS.

BY GEORGE B. PRESCOTT, JR.

THAT there exists at the present time much uncertainty respecting the absolute resistance of pure metals and their alloys is generally well known, and may easily be ascertained by any one who chooses to compare the tables to be found in the current electrical text books. It is evident, furthermore, from the correspondence columns of the electrical journals, that this condition of affairs is a source of some confusion and annoyance to electrical manufacturers and artisans, who understand the importance of using metals of the highest conductivity in the construction of their apparatus and distributing systems. To explain the cause of this disagreement and to present, if possible, some reliable evidence respecting the best authenticated, and, therefore, most trustworthy figures for the specific resistance of the more commonly used metals and alloys, is the purpose of this article.

From a scientific point of view, it is doubtful whether knowledge of the mean specific resistance of the pure metals and their alloys would be considered of much value, as the electrical properties of any substance can be positively expressed in terms of its absolute specific resistance or conductivity, without reference to any arbitrary standard, such as the average conductivity of a pure metal. Dr. Matthiessen has demonstrated, moreover, that the values for the specific resistance of even chemically pure electrotype copper, when determined with ordinary care, differ for different specimens by as much as 1.6 per cent., and other metals differ to a greater or less extent. This he attributes to the fact that the molecular structure of even pure metals is not the same for different specimens of the same kind of metal. Where great accuracy is desired, therefore, all of the physical qualities of the particular samples experimented upon must be ascertained and taken into account.

Nevertheless it is the common commercial practice, dictated no doubt, by considerations of practical convenience, to indicate the quality of wires for electrical uses in terms of their conductivity as compared with that of a similar wire of pure metal of the same kind; and if such standards of reference are to be employed at all, it is certainly desirable that they should agree. Now, as the standards of conductivity which circulate in the commercial world, have been derived from the figures for the resistance of metals as given in the electrical text-books, which differ to a marked extent, they also fail to harmonize, and the confusion alluded to results.

So far as the writer, who has taken some pains in the matter, has been able to discover, the experiments of Dr. Matthiessen in connection with the work of his collegues, Messrs. Von Bose, Vogt and Hockin, on the specific resistance and relative conductivity of the metals and alloys, and on the effect of temperature on their conductivities, have been generally accepted as authoritative, and the values determined by them universally adopted as the basis for tables of resistance, and formulæ for temperature corrections. No less an authority than Clerk-Maxwell says in his "Electricity and Magnetism," that there is no part of electrical research in which more numerous or more accurate experiments have been made than in the determination of the resistance of metals, and that the electrical properties of metals and alloys have been studied with great care by Messrs. Matthiessen, Vogt and Hockin.

As the results of Dr. Matthiessen's researches supplied the data from which the British Association Committee determined upon the practical standard of resistance, and as the first comprehensive tabulation of these results by Professor Fleeming Jenkin, a member of that committee, appeared in a volume of their reports,[1] it is reasonable to presume that the figures given therein, and in Matthiessen's published researches, are the standards commonly referred to. This being the case, the question naturally suggests itself, Why should tabulations based on figures derived from the same experiments, differ so widely when made by different persons?

In a previous article[2] the writer, in referring to the marked discordance between the values for the specific resistance of copper, given in various electrical text-books, called attention to the fact that one cause for this lack of agreement could be traced directly to the reports of the British Association Committee referred to above. In the third report, 1864, there appear two different figures from which the specific resistance of hard and soft copper may be deduced, and both have been quoted as standards in numerous instances. The first is given by Dr. Matthiessen and Mr. Hockin, in a table in appendix C, to the 1864 report, and states that :—

The approximate resistance of a metre-gramme of pure hard-drawn copper at O° C. = 0.1469 *B. A. unit.*

The second appears in the body of the report in a table showing the approximate relative values of various units of electrical resistance, and states that :

The resistance of a Matthiessen unit, viz., one English standard mile of pure annealed copper wire $\frac{1}{16}$ *inch diameter at* 15.5° *C.* = 13.59 *B. A. units.*

If these two values are reduced for similar dimensions and temperature, and due allowance be made for the difference between the conducting powers of hard-drawn and annealed copper, a considerable disagreement will still be found to exist between them, and this difference is the source of error referred to in the article mentioned.

It is here essential to note the fact that while the first of these figures specifies the resistance of a given weight and length of copper, the second specifies the resistance of a given length and cross-section of copper. In other words one expresses the dimensions in terms of length and mass, the other in terms of volume. Now in order to deduce the resistance of a material per unit volume, from its known resistance per unit length and mass, the specific gravity of the material must be determined. This requirement appears to have been a prolific source of the disagreements as to the resistance of metals, particularly in the case of mercury, in terms of the specific resistance of which the legal ohm is defined; for it will appear that various writers have employed different specific gravities in tabulating Dr. Matthiessen's observations.

Although for commercial purposes it is found to be more convenient to express the resistance of materials in terms of length and cross-section, all of Dr. Matthiessen's later measurements were made from given lengths and weights of the materials he experimented on, because he found it to be impossible to measure the diameter of a small wire with the accuracy with which the weight can be determined. Moreover, the cross-section of a wire is not generally a circle, and the mean diameter varies slightly from point to point, however carefully it may be drawn.

A great oversight was made by Dr. Matthiessen in not observing the specific gravity of each wire experimented on, so that the results could be compared with former experiments. On this subject he says in the B. A. report :

> "*This omission was first made because it was thought that the results of former experiments could be used; but after several measurements had been made it was found that the values of the specific gravity of wires of the same metal, given by different observers, varied so much that it was impossible to find the resistance of a wire of a metal of which the length and sectional area are known, from the resistance of a wire of which the length and weight are known, without taking the specific gravity of the wire actually experimented on.*"

The system of measuring the conducting power of substances by comparison with that of some other bodies such as silver or mercury, which Dr. Matthiessen unfortunately employed, although he frequently pointed out the discrepancies thus produced, has also been the source of much confusion to those who have since undertaken to tabulate his results in a more convenient form.

In attempting to explain how the resistance tables in some of the more frequently consulted text-books come to differ from each other, although their constants have ultimately been derived from the same source, it will perhaps be well to first explain what is meant by absolute and specific resistance or conductivity. The word "absolute" is only used in contradistinction to the word "relative," and by no means implies that the measurements or units are absolutely correct, but that the measurement is made by reference to fundamental units of another kind, and not by a simple comparison with an arbitrary quantity of the same kind.

---

[1] *Reports of the British Association Committee on Electrical Standards.* Edited by Fleeming Jenkin, London, 1873.

[2] THE ELECTRICAL ENGINEER, June, 1888.

The specific resistance of a material referred to unit mass and length may be defined as the resistance of the unit mass formed into a conductor of unit length and of uniform section. Thus the specific resistance of a metal in the C. G. S. system is the resistance of a wire of that metal one centimetre long and weighing one gramme. The specific resistance of a material referred to unit volume may be defined as the resistance between opposite faces of a cubic centimetre of the material. Specific conducting power or conductivity are terms employed to express the reciprocals of specific resistance as referred either to unit mass and length or to unit volume. Now, as the unit of weight in the C. G. S. system, the gramme, is the weight of a cubic centimetre of water at maximum density, and as the density of a cubic centimetre of water is also taken as unity, it follows that:

$$\text{Resistance of unit volume} = \frac{\text{Resistance of unit length and mass.}}{\text{Specific gravity.}}$$

Turning now to the volume of B. A. Reports in expectation of finding the required data, one is surprised to learn that, so far as Dr. Matthiessen's work is concerned, it relates almost exclusively to experiments on the effects of age, use and variations of temperature on the resistance of numerous alloys. Only one mention is made of the resistance of metals, with the exception of the table, already referred to, giving the values of various units of electrical resistance, in which the resistance of copper and mercury incidentally occurs. There are, however, numerous references to previous experiments made by Dr. Matthiessen, from which it appears that the results of these earlier determinations were accepted by the committee. These references[1] together with some obtained from other sources have been freely consulted, and it is believed that they cover the ground of Matthiessen's published researches.

In Table I., will be found the values for the resistance of some of the metals, as given by Dr. Matthiessen in the B. A. Report. Although not stated in the report, it has been learned from other records that the figures given are for the temperature 0° C., and that the mercury is liquid, the lead pressed, and the other wires hard drawn.

TABLE I.

Approximate Resistance of a Metre-Gramme of the Different Metals in Terms of the B. A. Unit.

From B. A. Rep., 1864

Metals	Resistance.
Copper	0.1469
Silver	0.1682
Gold	0.4150
Gold-silver alloy	1.668
Lead	2.257
Mercury	13.06

In the latter part of this volume of reports, however, there are reprinted several Cantor lectures by Professor Jenkin, which deal chiefly with the results of the committee's labors, and their appearance in this volume gives them authoritative value. One of these lectures contains a table of the specific resistance of metals and alloys based on Dr. Matthiessen's experiments, the resistances being calculated for a metre-gramme, a metre-millimetre, a foot-grain and a foot-mil of the various metals. As this table is frequently referred to as the authority for Matthiessen's figures, it will be interesting to note the means resorted to in compiling it. The numbers which appear in the metre-gramme and metre-millimetre columns of this table are given in Table II., together with the corresponding specific gravities which have been calculated from the numbers in those columns; also a cubic centimetre column taken from the same table in a later edition of Professor Jenkin's *Electricity and Magnetism.*

TABLE II.

Specific Resistance in B. A. Units of Metals and Alloys at 0° C. Calculated from Dr. Matthiessen's Experiments.

From B. A. Rep., 1873 and Jenkin's *Electricity and Magnetism.*

Name of Metals.	Specific gravity.	Resistance of a wire 1 metre long, weigh'g 1 gramme.	Resistance of a wire 1 metre long, 1 millimetre diameter.	Resistance between opposite sides of a cubic centimetre.
Silver annealed	10.15	0.1544	0.01937	1521
" hard drawn	10.17	0.1680	0.02103	1652

1. Platinum, 2 parts; silver, 1 part.
2. The alloy usually used for resistance coils.
3. Gold, 2 parts; silver, 1 part.

The underlined numbers are the direct observations of Dr. Matthiessen, and it will be observed that they agree with the numbers in Table I, with the exception of a slight difference in the value for silver which is probably due to an error in copying. The method employed in compiling this table is explained in Professor Jenkin's *Electricity and Magnetism*, in which it is reprinted with an additional column showing the resistance of the substances per cubic centimetre. The underlined numbers were first inserted in the metre-gramme column, and the metre-millimetre numbers obtained by taking the value 2.257 for the resistance of a metre-gramme of lead, and calculating the resistance of a metre-millimetre from the specific gravity, 11.376. The other numbers in the latter column were then filled in by making them inversely proportional to the relative conducting powers for equal volumes, as given by Dr. Matthiessen, when hard-drawn silver is 100 and the gold-silver alloy is 15.03. The metre-gramme column was next filled in by calculating the values for zinc, platinum, iron, nickel, tin, antimony, bismuth and mercury, from the metre-millimetre column by their specific gravities, the three alloys from specific gravities given by Dr. Matthiessen, and the soft silver, copper and gold from the ratio of their conducting powers to those of the hard-drawn metals. The figures in the foot-grain, foot-mil and cubic centimetre columns were obtained by comparison from the others.

(*To be continued.*)

A NEW INSULATING COMPOUND.

The large variety of insulating compounds already in existence has recently been increased by another, in which by combining two well-known bodies a material of high insulating properties together with other valuable characteristics is obtained. The new compound which has reecntly been invented and patented by Mr. A. A. Knudson, consists of a mixture of carbolic acid and shellac. The two substances are combined by heating carbolic acid until it boils slowly, and then adding the shellac, or other insulating materials, such as vegetable drying oils, asphalt, resin, etc. The product is a semi-plastic mass remarkably tough and tenacious, which is but little sensitive to extreme changes of temperature, and presents a hard smooth surface. The results obtained with this new compound have already proved very encouraging.

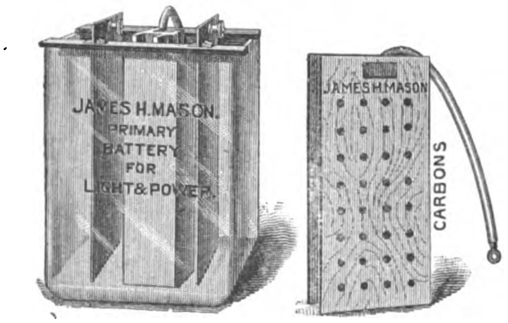
THE MASON PRIMARY BATTERY.

Although the dynamo has to a very great extent acted to place the primary battery in a position of secondary importance as a source of electrical energy, it cannot be denied that the battery nevertheless still occupies a sphere of some importance, and indeed has a legitimate field of use which it would be folly to ignore. A primary battery possessing merit, therefore, has a fitting place and as such deserves recognition. Thus in many situations where dynamo current is not available a battery can be very well applied for furnishing current to a small number of lights, for the driving of fans or sewing machines or the performance of other light work.

This has been recognized by Mr. James H. Mason, of Brooklyn, who has for some time past devoted his attention to the construction of a reliable primary battery, and one which shall require as little attention as possible. The cells constructed by Mr. Mason vary in size and capacity. One of these known as No. 11 cell is designed for 350 ampere hours with one charge of solution.

The cell, as shown, consists of a glass jar containing a porous cup which is specially prepared and made indestructible. This porous cup is intended to hold the Mason depolarizing solution and in which the carbons are immersed. There are two carbons which are cast together, the carbons being prepared with a special solution, which keeps the metallic parts of the casting always bright and indestructible. A heavy flexible wire is also cast in, the wire being well insulated with rubber and cotton, after which, as an extra protection, it is inserted in a flexible rubber tube. The end of the wire is then well soldered to a special terminal.



THE MASON PRIMARY BATTERY.

These carbons together expose over 300 square inches of surface to the depolarizing solution. On either side of the porous cup two zinc plates are suspended. These plates measure 12 inches long by 8 inches wide and ⅛ inch thick, and jointly expose over 325 square inches of surface to the solution. Polarization does not take place in the cell with this depolarizing solution.

The carbons are perforated with taper holes, measuring one-half inch in diameter at the large end and one-sixteenth of an inch in diameter at the small end. It will readily be seen that this plan exposes a considerable surface of carbon to the solution, while at the same time the small hole allows the solution to flow freely from one side of the plate to the other.

The work which the batteries of Mr. Mason have performed in various situations, and the fact that Mr. Mason himself well recognizes the proper limits to which a primary battery can be applied, are evidence of the character of the cell. We may add that the Empire Electric Company of this city have undertaken the agency for the same.

MAGNETISM.

BY DR. JOHN HOPKINSON, F.R.S.

(Concluded from p. 271.)

What explanations have been offered of the phenomena of magnetism? That the explanation must be molecular is apparent. Poisson's hypothesis was that each molecule of a magnet contained two magnetic fluids, which were separated from each other under the influence of magnetic force. His theory explained the fact of magnetism induced by proximity to magnets, but beyond this it could not go. It gave no hint that there was a limit to its magnetization of iron—a point of saturation; none of the hysteresis; no hint of any connection between the magnetism of iron and any other property of the substance; no hint why any magnetism disappears at a high temperature. It does, however, give more than a hint that the permeability of iron could not exceed a limit much less than its actual value, and that it should be constant for the material, and independent of the force applied. Poisson gave his theory a beautiful mathematical development, still useful in magnetism and electrostatics.

Weber's theory is a very distinct advance on Poisson's. He supposed that each molecule of iron was a magnet with axes arranged at random in the body; that under the influence of magnetizing force the axes of the little magnets were directed to parallelism in a greater degree as the force was greater. Weber's theory thoroughly explains the limiting value of magnetization, since nothing more can be done than to direct all the molecular axes in the same direction. As modified by Maxwell, or with some similar modification, it gives an account of hysteresis, and of the general form of the ascending curve of magnetization. It is also very convenient for stating some of the facts. For example, what we know regarding the effect of temperature may be expressed by saying that the magnetic moment of the molecule diminishes as the temperature rises; hence that the limiting moment of a magnet will also diminish; but that the facility with which the molecules follow the magnetizing force is also increased, hence the great increase of μ for small forces, and its most instantaneous extinction as the temperature rises. Again, in terms of Weber's theory we can state that rise of temperature enough to render iron non-magnetic will not clear it of residual magnetism. The axes of the molecules are brought to parallelism by the force which is impressed before and during the time that the magnetic property is disappearing; they remain parallel when the force ceases, though being now non-magnetic, their effect is *nil*. When, the temperature falling, they again become magnetic, the effect of their direction of their axes is apparent. But Weber's theory does not touch the root of the matter by connecting the magnetic property with any other property of iron, nor does it give any hint as to why the moment of the molecule disappears so rapidly at a certain temperature.

Ampére's theory may be said to be a development of Weber's; it purports to state in what the magnetism of the molecule consists. Associated with each molecule is a closed electric current in a circuit of no resistance; each such molecule, with its current, constitutes Weber's magnetic molecule, and all it can do they can do. But the great merit of the theory—and a very great one it is—is that it brings magnetism in as a branch of electricity; it explains why a current makes a magnetizable body magnetic. It also gives, as extended by Weber, an explaination of diamagnetism. It, however, gives no hint of connecting the magnetic properties of iron with any other property. Another difficulty is this: When iron ceases to be magnetizable, we must assume that the molecular currents cease. These currents represent energy. We should, therefore, expect that, when iron ceased to be magnetic by rise of temperature, heat would be liberated; the reverse is the fact.

So far as I know, nothing that has ever been proposed even attempts to explain the fundamental anomaly, why do iron, nickel and cobalt possess a property which we have found nowhere else in nature? It may be that at lower temperatures other metals would be magnetic, but of this we have at present no indication. It may be that, as has been found to be the case with the permanent gases, we only require a greater degree of cold to extend the rule to cover the exception. For the present, the magnetic properties of iron, nickel and cobalt stand as exceptional as a breach of that continuity which we are in the habit of regarding as a well-proved law of nature.

After the delivery of this address, **SIR WILLIAM THOMSON** said the president had done well to emphasize the marvellous properties of iron, nickel and cobalt, but he thought these properties were not quite so much isolated as would appear from the address. Faraday showed the continuity between paramagnetic and diamagnetic bodies, and that all substances are susceptible to magnetism when subjected to sufficiently intense magnetizing forces. He had also compared the relative susceptibilities of materials, such as glass, bismuth, wood, etc.; but the absolute determination of their susceptibilities still presents a large field for interesting and valuable research. The fact that the magnetic properties of such substances could be compared was itself of immense importance, whilst Tyndall's observations on the properties of bread, Iceland spar, etc., which can be made, or are naturally, magnetically anisotropic further enhances the interest connected with the subject. As regards the president's remark that Poisson's theory gave no hint of hysteresis, this, he thought, was open to question, for the theory refers to coercive force, and this is hysteresis under another name. Coming to the subject of recalescence, Sir William said this was of immense importance, and one of the wonders duly accentuated by the president. In this connection, he wished to add, that most of the work on latent heat of iron, about the temperature at which the recalescence occurs, had been done by the president himself. The region about the ripple in Fig. 13 requires further investigation, and, if possible, a cycle such as Andrews used in his experiments on evaporation and condensation should be devised. The material exists in two or more different states at the same temperature, and if the effect is reversible, then the iron should cool whilst heat is being applied to it. In conclusion, Sir William suggested that several physical properties of the material should be tested statically whilst it was kept at temperatures little above and little below the critical one, and also during the various states in which the material exists at the same temperature.

PROFESSOR EWING, in commenting on the enormous amount of hysteresis exhibited by the alloy of nickel and iron, Fig. 11, said he had looked for hysteresis in similar alloys and found none; now he saw why he found none, for his experiments were made between ordinary atmospheric temperatures and 212°F., whilst Dr. Hopkinson, by increasing the range of temperature, had passed the critical points and shown the hysteresis to be very great. In his own (Professor Ewing's) experiments on iron, he found that by tapping a rod whilst subjected to magnetizing force, a permeability of 20,000 could be obtained.

CORRESPONDENCE

NEW YORK AND VICINITY.

The Lenox Lyceum Electrical Exhibition.—An Electrical Eiffel Tower.—Mr. Kearney on Gas Mains and Steam Pipes.—The Apparatus for Executing Kemmler.—Subway Board Meeting.

THE Electrical Exhibition at the Lenox Lyceum, continues to be visited by a large number of people, and it seems likely that the attendance will be heavy during May, on the 15th of which it closes. The importance of the Exhibition is being more and more recognised, and one feature has been the number of celebrities visiting it. Dr. Wangemann, the able and courteous director of the phonograph department, has frequent opportunities of entertaining leading New Yorkers in his fascinating laboratory, not only with pithy little lectures on sound and music, but with the reproduction of some of the voices of great Europeans. An invitation to the Doctor's "den" is one of the honors of the Exhibition.

It is said that Mr. Henry Villard has promised, on behalf of the Edison Company, to have the electrical exhibit brought to the Minneapolis Exposition, which opens in August. It is also said that Mr. Eiffel has made a proposition to the World's Fair Directors to erect a similar structure in Chicago, and provide the entire capital needed for its construction should the directors approve of his proposition. It will be the joint erection of Mr. Eiffel and Thomas A. Edison, and will surpass in altitude the original structure by at least 500 feet. Mr. Edison, it is said, contemplates placing a million multicolored electric incandescent lights upon the structure, and making it one of the most marvelous and beautiful spectacles ever witnessed in the world. If this be so it is certain that Mr. Luther Stieringer, the designer of the Lenox "Tower of Light" will be very much in demand, to carry out the scheme.

At the investigation of the State Senate Committee on General Laws, which proposes to establish a State electrical board, Mr. Henry S. Kearney, chief engineer of the Board of Electrical Control, was called upon to testify on the gas and subway question in New York city. He said that the city is gridironed with gas mains ranging from four to 20 inches in diameter. In some streets, and on Sixth avenue especially, there are four sets of gas mains on each side of the street. Mr. Kearney says that gas is continually escaping from these mains from leaking joints, and he believed that in 95 out of 100 holes dug in the streets between 14th and 23d streets and 3d and 9th avenues, escaping gas would be found before the main was reached. In laying the conduits he found many gas mains so corroded that they broke in handling, and also found old service "cut-offs" made by simply hammering the ends of the pipes together. Mr. Kearney says the steam-heating pipes also gave them much trouble. Ten feet below the surface of Broadway, from Howard street to Exchange place, the temperature of the earth was above 100° F., caused by escaping steam from defective joints. This heat, in combination with acids in the soil, destroys the insulation on underground wires. The Telephone Company has been forced to lay a new cable especially prepared to resist these effects. The brass pneumatic tubes of the Western Union Telegraph Co., laid three years ago, are also badly corroded from these causes. Mr. Kearney thought these evils could be remedied, and was in favor of a supervisory board to control "the gas and steam companies." Mr. James W. Smith, President of the Consolidated Gas Co., appeared for the defense. He said that the gas mains were laid under inspection, and were as tight as it was possible to make them. They were injured by the frequent and careless tearing up of the streets. He said the quantity of escaping gas was over-estimated, instead of eight or ten per cent., as stated by Mr. Kearney, he did not think it was over one per cent. Mr. Smith claimed that the subways had been laid with absolute recklessness, and without regard for the rights of other underground work. In some places they had built solid brick and cement structures right on top of gas mains.

The Board of Electrical Control held a meeting in the Mayor's office last week and took a report presented by the expert of the Board, Dr. Wheeler, regarding the question, which was referred to him, of the effect of heat on the underground wires in Broadway. Dr. Wheeler reported that it did not seem practicable to make a cable the insulation of which would not be lowered by the increased temperature occasioned by the proximity to the subway of steam-heating pipes, inasmuch as all the best insulating substances vary in resistance with rising temperature. The matter of devising a method for reducing the heat in the subways was one which, Mr. Wheeler said, had been under consideration for a good while, and it did not seem to him that objectionable heating would be overcome for some time. Mayor Grant interrupted the electrical expert at this stage to say that it was proposed to remove and replace all steam-heating pipes in Broadway when the repaving is to be begun, and this, he said, would be within a few months. Dr. Wheeler went on to say that the question was consequently limited to the matter of safety without regard to the effect of heat on insulation considered from any other point of view. He read reports that had been made to him by other electrical experts, some of whom, it appeared, had submitted their opinions, not to Dr. Wheeler, but to the United States Illuminating Company. As soon as this fact came out Mayor Grant rudely declined to hear further, and roughly directed Dr. Wheeler to file a new report based on his own knowledge, and such other facts as he himself could acquire without the aid of any electric lighting company.

The career of William Kemmler is gradually approaching an end. He fully realizes his position, and intends to meet his fate unflinchingly. According to an Associated Press dispatch from Auburn, the arrangements for his execution are nearly completed. The death chamber is about 17 feet wide by 25 feet long, and is dimly lighted by two small iron-grated windows about four feet above the floor, from which a view of the main entrance of the prison can be obtained. Between the windows on the east wall is a long board about 10 feet in length and 3½ or 4 feet high. On this board are arranged appliances for testing, measuring, and governing the death-dealing current. At the left is a push button, which communicates with the dynamo room, and is used for signaling. Next on the right is a Cardew voltmeter, a box containing a coil, and surmounted by a gauge which registers the E. M. F. in volts. Another box, on the right contains a reducing coil to reduce the voltage before it enters the voltmeter or the lamp box on the right.

Between the reducer and the voltmeter is a small switch to turn the current off and on the meter. The lamp box contains twenty-four sixteen-candle-power incandescent lamps, and shows when the current is on and running steadily. Then come two switches, one for short circuiting the current, the other the fatal switch which carries the current to the wires connecting with the body of the condemned man. Two wires at the top connect with a dynamo 1,000 feet away in the north wing of the prison. One of the wires at the bottom will be connected with the metal cap to be worn on the head, and the other will be adjusted to the base of Kemmler's spine.

At present these two wires remain dangling from the ceiling. They will be attached to a board three feet square fastened to the ceiling, which is already in position, and which is directly over the spot where the chair is to be placed.

NEW YORK, April 28, 1890.

BOSTON.

Boston Harbor Protection.—Electric Light Warfare.—Electric Legislation.—Committee Reports.—Municipal Control of Electric Light Plants.—Consolidation of Gas and Electric Interests.—Inspection of Electric Lights.—Boston Electric Club.—First Ladies' Reception a Grand Success.—Next Meeting of the Club.—Work in the Common Council.—Speed of Electric Cars.

THE War Department are preparing plans for a system of casemates, or underground stations, for the operation of submarine torpedoes in Boston harbor should they ever be required. These casemates will contain complete electric apparatus for the exploding of torpedoes, though the torpedoes themselves will not be placed unless it is found necessary to protect the harbor from some foreign invasion. The placing of the torpedoes is a work of but a few hours, and with the wires run into casemates the operators are secure from danger.

The gas commissioners Wednesday morning heard the petition of the Boston Electric Light Co. that the attorney-general be requested to proceed against the Suburban Light and Power Co. E. W. Burdett, counsel for the Boston company, claimed that the Suburban company was maintaining a plant and erecting wires without a license from anybody. Mr. Burrage, for the Suburban company called the attention of the commissioners to the law under which the action was asked for, which makes it necessary for the board to satisfy itself by investigation that the law is being violated. The commissioners reserved their decision.

The Legislature has had various electric interests under consideration, and several committee reports have been made this week. The committee on manufactures made a report relative to their investigations at Alexandria, Richmond and Philadelphia as to the manufacture and sale of gas and electric lights by municipalities. The committee does not consider it advisible to recommend the adoption of municipal control of gas or electric light works in Massachusetts cities and towns. The same committee reported a bill to authorize the consolidation of gas and electric light companies, and also a bill providing for the inspection of electric lights and meters to ascertain the candle power and energy consumed by electric lights, and to test electric meters.

The rooms of the Boston Electric Club were the scene of one of the most pleasant gatherings which have ever taken place under the auspices of the club. For months past there have been many suggestions from members that there should be a ladies' night, and the house and entertainment committee have reason to be congratulated upon the immense success of their effort to comply with the general wishes of the members. The rooms were handsomely decorated with flowers, electric fixtures, numerous pictures representing various electric interests; and the splendid array of birds, kindly loaned by Mr. A. B. Griggs, a popular member of the club, were tastefully suspended from various points, giving the rooms a decidedly cosy appearance. About one hundred and fifty ladies and gentlemen were present. Entertainment had been provided for them in the shape of a unique exhibition of the phonograph which elicited much applause with its marvelous reciting abilities. Two handsome speaking dolls, kindly loaned for the occasion by the Edison Phonograph Toy Doll Co., also attracted a great deal of attention, and were a source of endless amusement to the ladies and their escorts. These dolls are made to recite some well-known nursery rhyme upon the turning of a crank, and when well manipulated speak in remarkably distinct tones, considering the source of speech, and their moderate price. A suitable banquet was provided for the refreshment of the members and their guests, under the able management of the club steward, Mr. William Allen, the menu being neatly printed on the rice paper napkins, which were eagerly seized upon as an interesting memento of the first night of the kind in the annals of the club. Each gentleman was presented with a boutonniere on entering, while the ladies were also the recipients of a neat corsage bouquet. Most of the arrangements were made under the supervision of Mr. Alex. P. Wright, the popular secretary of the house and entertainment committee, who deserves great credit for the perfect arrangements and complete success of the evening. It is hoped that many more such entertainments will be provided in future as everyone was entirely pleased.

The next important meeting of the club will be on Monday, the 28th inst., at the club rooms, when Mr. George W. Mansfield will read a paper on "Single and Double Trolleys for Electric Railways." Mr. Mansfield is well known as an earnest worker in the practical field of electric railway work, and there will undoubtedly be a large attendance.

Through some error of manuscript it was stated last week that the New England Wiring and Construction Co. had secured the contract for the *Telephone* Exchange building. Such is not the case. What was intended was the Stock Exchange building on State street, now in course of construction, which the New England company will commence to wire as soon as ready. The contract for the new Telephone building on Milk street, has not yet been given out, and indeed it is not yet decided whether electric lights will be used.

At a meeting of the board of the Common Council, an order providing for a visit to New York city and Philadelphia in order that electric lighting plants there may be examined, with a view of introducing one into the Boston City Hall, was presented, discussed at length, and finally passed, and the council refused to reconsider it; also the council concurred with the aldermen on the following order:

"That the joint special committee on electric light plant for City Hall be authorized to report estimates for furnishing and establishing an electric light plant in the basement of City Hall, for lighting City Hall, the courthouse in Court square and the registry of deeds building."

As a result of the recent public hearing regarding the rate of speed of electric cars, the Board of Aldermen as a committee of the whole has decided to report to the board next Monday in favor of increasing the rate of speed from Westchester Park to Pleasant Street, on Shawmut Avenue, from seven miles an hour to ten miles an hour between Pleasant Street and other points in the city proper. From Westchester Park out through Dorchester and Roxbury the speed will be twelve miles an hour, and this order will apply to the Brighton section.

Mr. F. M. Gilley, of Chelsea, read an exceedingly interesting paper before the Society of Arts in Boston this week, on "Central Electric Lighting Stations in London." The lecture was profusely illustrated with stereopticon views.

BOSTON, April 26, 1890.

PHILADELPHIA.

The Telephone Service.—The New Franklin Institute Building.

AT a special meeting of the Maritime Exchange a few days ago it took up the question of Philadelphia's telephone service, and after a short discussion referred the matter to the Room Committee of the Exchange. Secretary Edward R. Sharswood said that the Exchange had been somewhat misrepresented. It is ready to join heartily in an investigation of the service.

Audubon, which is a pretty New Jersey town just out of Camden, has push and energy about it. Arrangements are being made for an extensive electric light plant. It will be completed in a short time, and then Audubon will be one of the few New Jersey towns lighted by electricity.

The arrangements for the erection of a new building for the Franklin Institute are at length beginning to take definite shape, and it is expected that a site will be secured early next month. The construction of this building is an absolute necessity, as the Institute has one of the most valuable scientific libraries in the country, which, in its present quarters, is in danger of being destroyed by fire at any moment. The original committee of seven on the new building was last autumn enlarged to a committee of 100, but its work was delayed by the absence in Europe of Joseph M. Wilson, the architect. Since his return, however, the sub-committee on finance has resolved to raise $100,000 by subscription, and it has already obtained $40,000 of that amount, principally from the members of the committee of 100. It is estimated that from $300,000 to $400,000 will be needed for the purchase of the site and the erection of a handsome fire-proof building.

A charter was issued at Harrisburg yesterday to the Michales Electric Mining Machine Co., of Pittsburgh, with a capital of $500,000.

Electric lights will soon gleam from two 350 feet towers at Cramer Hill, a suburb of Camden, N. J.

PHILADELPHIA, April 25, 1890.

ST. LOUIS.

Bills in the Municipal Assembly.—Electric Railway Work.—Extension of Electric Lighting.

THE Municipal Assembly resumed summer sessions last Tuesday, at which the following electrical bills were introduced: The Bell Telephone Co., of Missouri, ask for the privilege of laying their own subways. The Postal Telegraph and Cable Co. ask for the privilege of laying a subway from their cable landing at the foot of Biddle street to their main office on Olive street. The North and South Rapid Transit Railroad ask for the privilege of constructing a double track street road from Cherokee street in the south part of town, across Eighteenth street bridge to Calvary cemetery in the extreme north end of the city, with two branch lines down town. Electric power, cable, gas motor or horses may be used as motive power.

The Cross Town Railway proposes a similar route, beginning at the cornor of Park and Mississippi avenues in the south end of town across the Eighteenth street bridge to North Market street. Any kind of motive power is permitted.

The bill of the St. Louis Central and Western Railway Co. has been signed by the mayor. A permanent organization of this company was effected this week, at which Jos. C. George was elected president, Geo. L. Peabody, vice-president, and H. E. Warner, secretary and treasurer. Preparations for the electric extension to Forest Park will be taken up immediately. It is also given out that the new company are considering the advisability of equipping the entire line with electric power and abandoning their cables. The old road (the Cable and Western) having a number of short curves has always been very expensive to operate.

The Electric Lighting Committee of the Board of Public Improvements, have recommended that an ordinance be prepared providing for the lighting with electric lights of that part of the city south of Keokuk street. The territory south of Keokuk street is now lighted with gas by the Carondelet Gas Co. Their contract with the city expires June 1. The new contract when authorized will fall to the Municipal Electric Light and Power Co. for the arc lights, and to the Missouri Electric Light and Power Co. for incandescent lights.

The St. Louis Railroad Co.—the Broadway line—will hold a meeting May 5, for the purpose of voting upon a proposition to increase the capital stock from $1,000,000 to $2,500.000 and the bonded indebtedness to $2,000,000. The object of this increase is to equip the main line with cable and the Seventh street section with electric power.

L. M. Chipley, financial agent, has brought to notice a scheme for a street car loop line, in the centre of the city to be used by all street car lines. The route proposed covers Fourth and Sixth streets and Clark and Franklin avenues. The Union Depot Line who already have a loop line covering almost the same territory, do not favor the scheme. All other roads are favorable to the scheme. In order to accommodate all the roads, both cable and overhead electric supply will be used.

ST. LOUIS, April 25, 1890.

CHICAGO.

The Morgan Electric Coal Cutter.—The Fort Wayne Central Station.—Foree Bain's Work.—Applications of the Pumpelly Storage Battery.

A NEW and ingenious coal cutter has just been devised by Mr. Morgan, of this city, who has given the problem much thought and attention. The operation of the machine is effected by a combination of the solenoid and horse shoe magnet principles and not by means of a rotary electric motor as in the machines designed heretofore for this class of work. It comprises the electromagnetic actuating apparatus by means of which a powerful spring is compressed, the expansion of the latter operating an ordinary pick such as is employed in the Harrison and other air machines. The arrangement is such that the solenoidal magnet exerts a very powerful pull upon its core, thereby compressing the spring; a switch is then automatically actuated which sends the current in opposite directions through the two halves of the solenoid neutralizing its magnetic actions, whereupon the spring comes into action and causes the pick to strike a powerful blow. The machine is calculated to absorb about 3 h. p., and is claimed to be highly efficient in operation. Mr. Morgan is now engaged in thoroughly testing his invention.

The Fort Wayne Electric Co. of this city, who are supplying current from their station to some 4,000 incandescent lamps by the well-known Slattery induction system are contemplating an increase of plant to double its present capacity, and will put the work in hand right away. Ever since the start, they have been continually pressed for more current and have been putting in new machines to fill the demand right along.

Foree Bain has just installed one of his new type of motors in the Chicago Paper Co.'s building. The motor is of 7 h. p. capacity, and is used for running the elevator and cutting machines. It does its work with the greatest ease and is giving the greatest satisfaction. The gas engine which formerly did this work is like Othello with "its occupation gone."

The Pumpelly Storage Battery and Electric Motor Co. have just closed a contract with Mr. C. M. Woodbury, of the Middlesboro Town Co., Middlesboro, Ky., to equip three cars with their storage batteries. These cars were built by the John Stephenson Co. of New York, and are now being fitted out with motors, etc., at Detroit. They are to be fully equipped and in operation by May 20. The storage battery is gradually gaining ground in electric traction work and the operation of these cars will be watched with much interest. Among other applications of the storage battery, this company has installed a set of their cells in the new apartment house built by Dr. Johnson, on 37th street and Lake avenue. The electric light is furnished to the occupant from an isolated plant located in the building, the dynamo running until 9 P. M., after which hour the light required during the night is furnished by the storage batteries. This, it is stated, is the first plant of the kind installed in an apartment house in the west, for the benefit of the occupants, and will undoubtedly be followed by numerous similar applications, as the advantages obtained by having a constant and ever present supply of light without the attendant annoyance of continual moving machinery are very apparent. This is one of the cases in which the utility of the storage battery is very clearly demonstrated. A special switch has been designed for this company by Dr. Paul Schoop, for use with cells when charged by means of a dynamo operated by wind power. This switch is perfectly automatic in its action and both makes and breaks contact and takes care of the cells and dynamo, rendering them independent of any variations in power or other troubles liable to arise and completely solving the difficulties which have been hitherto encountered in such plants. It is being used for this purpose at Batavia, and has given the greatest satisfaction.

CHICAGO, April 25, 1890.

PITTSBURGH.

An Electric Railway Strike.—New Electric Railway "Deals."—Westinghouse Statistics.

SIX of the firemen employed at the power house of the Pleasant Valley Electric Street car line in this city, went on a strike last Sunday morning for an increase in their wages. The men have been getting $1.63 per day, but a week ago they asked for $2.00 per day, which the company, however, refused, and the result was, that the men left their jobs last Sunday. The company has since succeeded in getting new men in the strikers' places and the operation of the street cars was but very slightly interfered with.

The street railway syndicate, which is composed of H. Sellers McKee, of Pittsburgh, Murray Verner, of Buffalo, and E. H. Clark, of Drexel, Morgan & Co.'s Philadelphia banking house, is reported to have purchased another street railway system. This time these men are said to have bought the entire street car lines of Louisville, Ky., paying $1,200,000 for them. The street railways of Louisville are antique in the extreme, and with the exception of those on the downtown streets, are operated on the switch system. The suburban branches do not extend as far as they could with profit. The Broadway line and the Sixth avenue line have been great money makers, and the prosperity of the latter dates back to the establishment of the exposition at its terminus. Several years since the lines all over the city were consolidated and the equipment was somewhat improved, but rapid transit was apparently unthought of until Messrs. McKee and Verner took in the situation and its possibilities. Negotiations were commenced two weeks ago and the transfer was made last week. The company in Louisville will be reorganized and a reconstruction of the entire system will be inaugurated. Electricity will be the motive power on all the lines. Which system, however is to be used has not been decided yet. Bonds will be floated to meet the cost of equipping the road. This is a method, which the syndicate has successfully tried in Buffalo, Rochester, Syracuse and Newark, the other cities in which this syndicate has control of the street car systems. In Pittsburgh, $1,500,000 worth of their bonds are now on the market. The syndicate is still looking for other cities. Columbus, O. was offered for sale, but the Elkins-Widener syndicate got in first and now owns the system. Indianapolis was also considered, but since Mr. Harrison went to Washington to live, the bottom dropped out of things in the "Hoosier capital," and everybody walks to save money.

Mr. Murray Verner, who has heretofore acted as negotiator and appraiser, became a member of the syndicate in the Louisville deal. Pittsburgh at this rate will soon have all the available systems of the country in the hands of her citizens. An enormous "deal" is said to be now pending, which will be as big as all the rest of the deals put together.

The motor department of the Westinghouse Electric Co. where the motors and other appliances of the Westinghouse electric street car system are manufactured, is now in full operation. The company received the other day a contract from the Lansing Street Railway Co. for a complete equipment of their line with the Westinghouse motor.

The Washington Carbon Co., of Washington, Pa., is now erecting an addition to its works which will greatly increase the capacity of the concern. The probability is that the largest portion of the plant will be under roof by next June, giving the company an opportunity of manufacturing every day from 50,000 to 60,000 carbon points.

Work has been commenced on the Wilkinsburg Electric line. The tracks are being laid now and the company expects to have its cars running by next September.

A comparative statement of the sales of the Westinghouse Electric Co. for the first quarter of 1889 and 1890 shows these figures: 1889, $621,336.92; 1890, $1.111,970.41, or an increase of 80 per cent. If this is kept up, the present year's business will aggregate about $7,500,000, as against $4,500,000 in 1889.

PITTSBURGH, April 25, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

LOSS BY HYSTERESIS.

[124]—In his letter (121) appearing in your issue of April 9, page 221, Mr. N. Tesla in discussing the losses due to hysteresis in transformers takes the ground that such losses outside of the generation of electrical currents, or independent thereof, are "difficult to reconcile with our present notions on the constitution of matter generally." Further on he says: "We cannot imagine that an appreciable amount of energy should be *wasted* by the elastically connected molecules swinging back and forth from their original position," etc. While I agree with Mr. Tesla that the actual loss referred to may be due to molecular currents, yet we have no proof of such fact. Again Mr. Tesla seems to forget that *loss, waste*, and such terms, are more scientifically rendered, by the words "*conversion into heat*," and that in nature nothing is wasted or lost, but merely converted.

Now we may consistently amend his quoted statement as follows, and see how it reads: "We cannot imagine that an appreciable amount of energy should be converted into heat by the elastically connected molecules swinging back and forth from their original positions," etc

Heat action is that swinging back and forth referred to, namely, "molecular vibration," and if we find that such swinging takes place we must have heat as a result. When the molecules can polarize or turn without being given a swinging movement or vibration, no conversion into heat takes place. The difference then between very soft iron and hard steel so far as magnetic waste goes, is, apparently, that in the soft iron there is less disturbance of position of the molecules during magnetization and reversal then in steel, assuming the degree of magnetization or polarization to be equal in each. The *waste* or conversion due to electrical resistance is of the same nature. Whenever the ether strain can be transmitted from molecule to molecule of the conductor without much disturbance of their positions or without causing a swinging out of position back and forth, the conductivity is great and the reverse is true with bad conductors.

In like manner, bending a bar of tempered steel back and forth within limits is mechanically efficient because very little conversion of motion into heat takes place, and this is a result of the relative positions of the molecules being preserved; while, bending a bar of inelastic metal, as a copper rod of moderate hardness, produces heat by disturbance and swinging of molecules. Such bending is inefficient.

There is then to my mind no more difficulty in understanding that a conversion into heat may be produced magnetically than electrically, or mechanically. Indeed, if, as seems probable, these actions are but variations of ether strain phenomena they are reducible to a single effect, and represent the molecular disturbances produced by transmission of ether strains. Cohesion, gravitation and forces acting between molecules, must of course be recognized as results of ether strains.

Molecules themselves, or matter itself, may be resolvable into ether movements or vortices, and we may be able to put "energy indestructible" in place of "matter indestructible" and mean as much. We need to forget the universe as made up of pieces, entities or particles, put together and allowed to interact and react, and learn to regard it as a consistent whole from which nothing can be taken without disturbing the balance or equilibrium of what remains. It is in my view more legitimate to attribute the heating effects of Foucault currents and other currents to a general molecular friction or hysteresis of conduction, if we may use such a term, than to assume the production of molecular currents in the heating or conversion of magnetic hysteresis. We have no present need of currents in accounting for heat conversion of mechanical friction and molecular friction of inelastic bodies when bent or distorted by mechanical force. Neither can we deny that theoretically such conversion into heat may be accompanied by molecular electric currents similar to eddy currents or Foucault currents, but infinitely more restricted as to length of circuit. On these points and others of equal interest we may speculate, but are in need of more facts to confirm our speculations.

ELIHU THOMSON.

LYNN, MASS.

WORDS OF GREETING.

This important American electrical journal which has appeared monthly since 1881, will hereafter appear weekly under the direction of T. Commerford Martin and Joseph Wetzler, who have left *The Electrical World* in order to devote themselves exclusively to THE ELECTRICAL ENGINEER. In view of the development of *The Electrical World* under the direction of Messrs. Martin and Wetzler, we can only express to our contemporary our regrets at this sudden change, and, on the other hand, congratulate THE ELECTRICAL ENGINEER on its new organization.—*L'Electricien*, Paris.

The appearance, on April 7, of the first weekly issue of THE ELECTRICAL ENGINEER, is noteworthy for several reasons. The journal started as a monthly, and, up to the date of the change, just ninety-nine numbers had been published under the editorial management of Franklin L. Pope and George M. Phelps. Under the new régime, Mr. Phelps remains as president of the corporation; T. Commerford Martin and Joseph Wetzler, formerly of the *Electrical World*, occupy the editorial chair; Frank R. Colvin is treasurer and business manager; and the management of the branch offices in Boston and Chicago will be in the hands of A. C. Shaw and W. F. Collins respectively. It is safe to say that a finer working team of journalists could not readily be got together. We extend to our valued contemporary our best wishes that all its hopes may be realized, and that its future may be abundantly bright and profitable.—*Practical Electricity.*

The issue of THE ELECTRICAL ENGINEER for April 2. is the first on a change from monthly to weekly. The periodical has been in existence for over eight years, and has become one of the most valuable electrical periodicals in the country. Hereafter it will be issued weekly. This periodical treats everything new in electrical science in a sufficiently technical and careful way to make it of value alike to the student and the practical man.—*Berkshire County Eagle.*

THE WHELESS ELECTRIC RAILWAY SYSTEM.

For several months past experiments have been carried on by Mr. Malone Wheless, at Washington, D. C., on a new system of operating electric cars, and as a result a trial of the system was made last week in the presence of a large number of prominent gentlemen. The test took place in a large open field near the power house of the Eckington electric road, and on which a rough track had been laid, which includes grades of 10 and 12 per cent.

The principal feature of Mr. Wheless' system consists in a novel method of conducting the current to the motor on the cars. Between the rails a shallow insulated conduit is built, through a narrow slot in which a wheel makes contact with the power wire.

At intervals of 90 or 100 feet the power wire is broken and connected with traps, into which a buried wire leads that carries the current from the power house. The novelty of the system consists in having only that section of the power wire vitalized or charged on which the car happens to be at the time. This is done by a small storage battery on the car closing the connection between the conducting wire and the power wire in the conduit, the circuit being made and broken in the traps by a system of electro-magnets. By this means no part of the power wire is charged except the one section of 90 feet with which the trolley is in contact. This prevents the leaking of current and reduces the line resistance.

The tests were very successful, the heavy grades and curves being easily surmounted with the car heavily loaded.

Mr Wheless claims that the initial cost of construction will not exceed $5,000 per mile and that the cost of maintenance is very small.

LIST OF SPRAGUE ELECTRIC RAILWAYS.

We are indebted to the Sprague Electric Railway and Motor Co. for the following list of their roads:—

Railways.	No. of Motor Cars.
Akron, O., Electric.	24
Asheville, N. C., Electric	8
Atlantic City, N. J., Electric	17
Augusta, Ga., Street	16
Baltimore, Md., North Ave., Electric	1

Making a total of 1,228 motor cars.

REPORTS OF COMPANIES.

ANNUAL REPORT OF THOMSON-HOUSTON ELECTRIC CO.

THE following is the report of the Company dated February 1, 1890, just issued:

CAPITAL STOCK AUTHORIZED BY CHARTER:

Preferred Stock	$5,000,000.00
Common Stock	10,000,000.00
Total	$15,000,000.00

CAPITAL STOCK PAID IN FEBRUARY 1, 1890:

Preferred Stock	$1,000,000.00
Common Stock	4,500,000.00
	$5,500,000.00
Surplus	$1,685,415.92
Total Paid-up Capital and Surplus	$7,185,415.92

Sales of preferred stock since February 1, 1890, for which cash has been paid in........ $1,650,225

Statement of Profits and Surplus Account.

	Added to Surplus from Profits.	Total Surplus.
January 1, 1883	$17,237.85	
" 1, 1884	93,696.74	$110,934.59
" 1, 1885	96,187.10	207,111.69
" 1, 1886	106,687.50	313,809.19
" 1, 1887	123,006.05	426,815.24
February 1, 1888	313,596.67	750,411.91
" 1, 1889	660,828.82	1,411,240.73
" 1, 1890	1,309,175.19	1,685,415.92

The surplus account February 1, 1889, was $1,411,240.73; from which there has been divided among the shareholders $1,000,000 as stock dividend, and a cash dividend of $35,000 on preferred stock. There has been added, as above, $1,309,175.19, making the present surplus $1,685,415.92. Before carrying the above amount to surplus there had been delivered to trustees "series D." securities and claims amounting at face value to $2,410,289.13.

The amount of annual business has increased from $300,000 in 1883, to $8,000,000 in 1889.

We have about 100 lines of electric railways under contract and in operation aggregating over 1,000 cars, as a result of less than two years' operations of this department.

Local companies using the Thomson-Houston arc and incandescent lighting system in the United States.

	No. of Companies.	No. of Arc Lamps.
January 1, 1883	5	365
" 1, 1884	31	2,478
" 1, 1885	59	5,867
" 1, 1886	100	13,227
" 1, 1887	171	21,849
" 1, 1888	303	36,936
" 1, 1889	419	51,621
" 1, 1890	587	68,203

There are companies operating this system in England, Italy, Ireland, Sweden, South and Central America, Finland, France, Germany, Spain, Russia, Japan, West Indies, Australia; in fact in nearly every civilized country in the world not included in above.

We have, in addition to the above, about 400 incandescent companies operating between 300,000 to 400,000 lights. We have also several hundred isolated plants in factories, hotels, etc., which number is rapidly increasing.

A full and detailed statement of all the operations of the company was presented to the stockholders at the annual meeting, held in Middletown, Conn., on Monday, April 14, and is on file at the office of the company. Full details of the assets and liabilities of the company are omitted from this exhibit for the reason that they embrace certain stocks of manufacturing and construction companies, and other valuable properties, which the directors believe they have been fortunate in acquiring, and which for obvious reasons, it is not considered wise to disclose in detail at the present time. The assets have been taken upon the usual conservative basis, a discount having been made of 60 per cent. from stocks held in local lighting and railway companies, and 30 per cent. from the first mortgage bonds of such companies. Large deductions have also been made from all other assets, and your directors believe that if the assets were inventoried as is ordinarily done by similar corporations the estimate of the value of your property would be *very largely* increased in amount.

The indebtedness of the company, which is less in proportion to the volume of business than in any previous year, has been reduced since the statement was made by the sale of a little more than a million and a half dollars of additional preferred stock.

The current business of the company is fully 100 per cent greater than a year ago with a corresponding increase in profits. Your directors have every reason to congratulate the stockholders of the company upon the present condition and future prospects of the business of the corporation.

THE NORTHWEST THOMSON-HOUSTON ELECTRIC COMPANY.

The Northwest Thomson-Houston Electric Company manages the business of the Thomson-Houston company of Boston in Minnesota, Wisconsin, Dakota, Montana, Idaho, Wyoming, Oregon, and Washington. It has a capital stock of $500,000, and handles Thomson-Houston electric supplies. From April 1, 1889, to April 7, 1890, the company sold about $1,000,000 worth of apparatus, and has in operation several central stations for city lighting, 49 isolated lighting plants and 18 electric railroads in operation or under construction. The company paid 10 per cent. in dividends during the past year, including the payment of April 7, 1890, and had a surplus April 1, after providing for the dividend, of $203,287 in bills and accounts receivable, securities, contracts, etc., including a nominal amount of cash. The balance sheet of April 1, 1890:

ASSETS.

Franchise and contract	$110,000
Stocks and bonds	164,500
Bills and accounts receivable	568,785
Real estate	500
Plants under construction	54,724
Railways under construction	43,708
Cash	13,603
Miscellaneous	3,415
Total	$1,078,141

LIABILITIES.

Capital stock	$500,000
Bills and accounts payable	374,853
Surplus	203,287
Total	$1,078,141

LITERATURE.

Electric Transmission of Energy. By Gisbert Kapp, C. E. New York: *D. Van Nostrand & Co.*, 1890. 348 pp. 126 illustrations. (Second edition, enlarged). Price, $3.

THE appearance of this new edition of Mr. Kapp's valuable treatise will be hailed with pleasure by all who are interested in the practical and theoretical questions involved in the generation, transformation, subdivision and distribution of current for motive power purposes. It may be said that Mr. Kapp has taken advantage this time of the elasticity of the title of his book, and has gone more fully into a treatment of the dynamo; but this is not a loss to the reader. On the contrary it is a gain, especially as Mr. Kapp has added his method for the predetermination of the characteristics of dynamos. The only regret is that he did not go even further and include some discussion of the alternating current for power transmission. That branch of the subject may still be new, but it is not the less "practical," besides being intensely interesting to a large number of intelligent workers and students. Moreover, there are, to-day, in America at least, alternating current motors actually at work.

Where there is so much that it is good, it seems hypercritical to point out omissions. Yet it is to be regretted that the book does not embrace more details with regard to electric railway operation. One looks in vain for a comprehensive or even cursory review, for example, of methods of overhead wire operation, although, as is well known, a tremendous amount of work and skill have been bestowed on that department of construction. The underrunning trolley wheel has been the subject of more rapid change and perfection than almost any other electrical device during the past two years, but the various innovations and modifications are all passed over in absolute silence. There would, moreover, be much of theoretical as well as practical interest in a treatment of such matters as single *versus* double trolleys; the use of the earth for the return circuit, and the employment of one motor instead of two on a car. Probably in England, these matters have not assumed any great importance yet, but with us they press for settlement. Mr. Kapp should visit America, see what is being done, and then write his third edition.

We can heartily commend this book. It is clear, incisive and impartial; throws light on many difficult points, and brings the reader squarely abreast of the advanced thought or best practice of the day. As far as it goes, it cannot be excelled, and no other work goes as far as it does in dealing with what is the great topic of the times for electrical engineers,—the utilization of electrical energy.

Electrical Influence Machines. By John Gray, B. Sc. New York, *D. Van Nostrand Co.*, 1890. 287 pages, 89 illustrations. Price $1.75.

STATIC electricity is not a branch of study that is specially favored in these days of heavy electrical engineering, when the whole tendency of practical work is toward the building of big dynamos and the handling of enormous current, but it has its place, and no one can safely assume that it may not at an early period regain some of the prominence and the interest that it had in times gone by. Indeed, the recent researches of Hertz, as well as the fascinating and suggestive experiments of Lodge, would indicate that the neglect of static electricity is likely to be succeeded by an intense concentration of thought and work upon it, opening up boundless fields of investigation for the scientist while providing new careers for the electrician and electrical engineer of the twentieth century.

The first portion of this excellent book unfolds the modern theories of the subject, Chapter 1 dealing with its experimental data and Chapter 2 giving us a "working hypothesis of the electric field." A separate chapter is devoted to electrometers, and Sir William Thomson's beautiful inventions receive therein their due share of attention. Part II is mainly historical and descriptive, and brings the record of evolution and improvement down to date. It is interesting to note that America is conspicuously absent from this review, although we observe a passing reference to the large Holtz influence machine built in this city by J. and H. Berge, with two rotating discs each 45 inches in diameter and yielding a 26-inch spark. Part III is admirable in the fullness and clearness of its details as to the actual construction of Wimshurst, Holtz and Voss machines.

BOOKS RECEIVED.

Spon's Tables and Memoranda for Engineers. By J. T. Hurst. Tenth edition. New York: *E. & F. N. Spon*, 1889. Price 40 cents. (Vest-pocket size).

Practical Electrical Notes and Definitions. By W. P. Maycock. New York: *E. & F. N. Spon.* 130 pp., illustrated. Price 60 cents.

Practical Electrics. A Universal Handy-Book on Every Day Electrical Matters. New York: *E. & F. N. Spon.* 135 pp., 5⅛ x 8¼, illustrated. Price 75 cents.

Inventor's Manual. New York: *J. F. Davison & Co.*

J. A. Berly's Universal Electrical Directory. London: *Wm. Dawson & Sons.* Ninth annual edition. 506 pp. Price $3.

Electricity in Modern Life.—By G. W. De Tunzelmann, B. Sc. Scribner & Welford, 743-745 Broadway, New York, 1890. Illus. 272 pp., cloth. Price, $1.25.

Lecons sur l'Electricite, Vol. I.—By Eric Gerard, Director of the Institute Electro-Technique Montefiore, of Liége. Gauthier-Villars et Fils, Paris, 1890. 558 pp., paper.

Die Zeittelegraphen und die elektrischen Uhren vom praktishen Standpunkte.—By Ladislaus Fiedler. Electro-technische Bibliothek, vol. XL. A. Hartleben. Vienna, 1890. 207 pp., paper. Price, $1.

Le Magnetisme Humain Considere comme Agent Physique.—By H. Durville. Librairie du Magnetisme. Paris, 1890. Pamphlet, 36 pp. Price, 25 cents.

Application de l'Aimant (Magnetisme Mineral) au Traitement des Maladies.—By Professor H. Durville. Second edition. Librairie du Magnetisme. Paris, 1890. Paper, 63 pp. Price, 35 cents.

Almanach-Annuaire de l'Electricite et de l'Electrochimie.—1890. France, Belgium, Switzerland. Firmin Leclerc. Paris, 1890.

SOCIETY AND CLUB NEWS.

CHICAGO ELECTRIC CLUB.

The following is the regular ticket for officers to be chosen at the annual election:—

President, F. G. Beach; vice-presidents, 1st, F. B. Badt; 2d, Alex. Kempt; 3d, D. P. Perry; 4th, W. H. McKinlock; secretary, W. A. Kreidler; treasurer, F. S. Terry; managers, B. E. Sunny, M. A. Knapp, F. W. Cushing, Geo. O. Fairbanks, Wm. Taylor, F. E Degenhardt, E. Baggot, F. W. Parker, Geo. C. Bailey, C. H. Wilmerding; membership committee, C. C. Haskins, Geo. Cutter, W. B. Pearson.

NEW YORK ELECTRICAL SOCIETY.

The society enjoyed a most delightful and successful reunion at the Lenox Lyceum Electrical Exhibition on April 25. Through the kindness of Mr. A. B. de Freece, the manager, a reduction in admission price was made, and Mr. George H. Guy, secretary of the society, had the pleasure of welcoming some 250 of the members and their friends. The tickets admitted to every thing, a special musical programme had been provided, and every body was more than satisfied with the artistic, scientific and intellectual treat.

NEWS AND NOTES.

ELECTRIC LIGHT AND POWER IN SEATTLE, WASH.

MR. E. C. KILBOURNE the president and manager of the Pacific Electric Light Co. of Seattle, writes us as follows:

"Our plant is now being installed, poles are up for two of the circuits and are rapidly being placed in position all over the business part of the city. We expect to be running May 1 with one 1,300-light Thomson-Houston alternating incandescent and one 45-light Thomson-Houston arc machine. The present outlook is that before we have been running 60 days we will be obliged to double our capacity. We are expecting to increase our power plant immediately by the addition of two large boilers and one 250 h. p. engine. In regard to electrical business generally in this city I will say that there are four electric light companies, including our own, with capacity for 600 arc lights and a little less than 7,000 incandescent lights, including 800 municipal incandescent lights. There are two electric railways already completed and in operation and one more building, and a power company furnishing power for stationary motors. Nearly all the printing presses in town are now being run by electricity. The rapid growth of Seattle keeps the electric companies busy meeting the demand for light, power and electric railways."

The Pacific Company will start with 10 miles of circuit. It is now in the market for its new engines and boilers. The other officers of the company are C. A. Kilbourne, secretary and C. P. Stone, vice-president and treasurer.

AN INDEPENDENT TELEGRAPH COMPANY PROPOSED IN CHICAGO.

A special dispatch from Chicago, of April 16, says: Whether or not the construction of a commercial telegraph line between Chicago and New York will be commenced within thirty days depends on the answer of Colonel R. W. Clowrey, First Vice-president of the Western Union Telegraph Co., returns to the demand made by the Board of Trade Committee to day that the forty-cent rate between the two cities be reduced to 25 cents.

The high rate went into effect April 1, when the telegraph company was forced to withdraw its offices from the floor of the board, when the war against the bucket shops was begun. At a meeting of members, recently held, a committee, consisting of Robert Lindblom, A. Poole, and C. F. Dwight, was appointed to secure a return to the old rate or put in operation a telegraph company which would construct a line to New York. The committee made its demand of Superintendent Tubbs to-day, but he said that in the absence of Mr. Clowry he could not return any answer to the committee. Mr. Clowry will not return until next week.

But the committee does not propose to be played with. At a meeting the subject of a new line was thoroughly investigated, and it was decided that the necessary money for its construction could be procured without trouble, and if the Western Union refuses to make a twenty-five-cent rate the committee decided to go ahead and form a company to build the line. As the committee consists of the same men who several years ago built a line to Milwaukee, their action means business.

A SOUTHERN TELEGRAPH TOURNAMENT.

A special dispatch from New Orleans of April 21, says: A large number of ladies and gentlemen assembled at the Board of Trade rooms yesterday afternoon to witness the first southwestern telegraph tournament under the management of Mr. E. J. Davis. In the sending contest speed, accuracy, and Morse were the points to be decided; each participant sent for five minutes.

The winners of the first prizes were W. S. Brewer, 211 words, superior Morse; J. B. Griffin, 194 words, superior Morse, and W. R. Wallis. The last named took first prize for receiving on typewriter in manifold. Brewer and Wallis are attachés of the Associated Press in this city.

. . . ELECTRICITY has now become in the words of a distinguished physicist, "a truly imperial science," in which physics and chemistry may be said to occupy the position of mere subordinate provinces.—*John Gray.*

. . . . THERE are two requirements with regard to the material suitable for aerial lines which are to a certain extent contradictory. The specific resistance of the material should be very low, and its tensile strength very high.—*Gisbert Kapp.*

OBITUARY.

Charles W. Jenks.

Mr. C. W. Jenks, who died April 9, was so widely known in electrical and manufacturing circles, that a sketch of his life presents more than ordinary features of interest. Colonel Jenks, as he was called by his friends and business acquaintances, was born at Southbridge, Mass., April 24, 1826. He was the son of Dr. Nicholas Jenks, a physician of reputation, a well known temperance and anti-slavery worker, and was one of a family of seven, of whom Professor J. W. P. Jenks, who has attained eminence in the scientific world as an authority on zoology, was for 30 years principal of Pierce Academy, Middleboro, Mass., and has for several years past occupied the chair of Natural History and Curator of the Museum at Brown University, Providence, R. I. The opportunities which Colonel Jenks enjoyed for obtaining an education were very limited. At 20 years of age he was employed in one of the hotels of Boston, and for 10 years was known as the most popular clerk in the city, being connected successively with the old Pavilion, Marlboro and Adams Houses. Here he laid the foundation of personal friendships with some of the most prominent public men of the time, and many of these acquaintances have been revived in the later years, with the events of which his friends of this decade are more especially interested.

After a dozen years of mercantile life he was first brought prominently before the public in connection with national affairs in 1869, by his editorship of *The Bureau*, a monthly journal published in Chicago, and devoted to the advancement of protection and the manufacturing industries of the West. By graphic and brilliant editorial articles, a new impetus was given to several growing branches of trade.

At that time the subject of Arctic exploration attracted wide attention, and the late Captain Silas Bent, of St. Louis, formerly of Commodore Perry's staff, on the famous expedition to Japan, became much interested in the views of *The Bureau* on the subject, and opened up a correspondence with the editor which ended in a firm and valued friendship. The course of the Gulf Stream and thermal winds as relating to meteorology being fully discussed, Mr. Jenks was led to take up the subject in connection with the shipping in our ports, in a series of articles which attracted the attention of President Grant, who called Mr. Jenks to Washington for a conference with him upon the subject, the result being the establishing of our present Signal Service system. Through the medium of *The Bureau*, a property in Missouri, which contained pure white sand was purchased by Mr. Jenks for the late Captain E. B. Ward, of Detroit, and a plate-glass industry—the first in this country—was successfully established in 1871, at what is now known as Crystal City, on Platin Creek. This has grown to large proportions, turning out as fine a quality of glass as can be made abroad, and greatly cheapening the commercial product. At the time of the Chicago fire, *The Bureau* office was destroyed, and he lost both business and home by the great conflagration.

Needing for the glass industry an abrasive, he next turned his attention to looking for such a polishing material, and in 1871, found in Macon County, near Franklin, North Carolina, a deposit of corundum which he opened and worked—the first instance of legitimately mining corundum in the history of the world.

The year following (1872) his energetic research disclosed to science for the first time the true oriental corundum gems (sapphire, ruby, emerald, topaz and amethyst) *in situ*, previously found only in the washings of the streams of the far east. On the occasion of a visit to Europe with some of these specimens, he was cordially received by Professor Forbes, as bearing new information in this branch of science, and delivered an address before the Royal Geological Society, the Duke of Argyll presiding. He afterward developed another corundum mine in the same vicinity, and these two are to-day the only paying mines of that character on the American continent.

In 1875, he connected himself with the National Association of Wool Manufacturers, as an assistant to the secretary, the late Hon. John L. Hayes. From that time he devoted much attention to the introduction through the South and West of thoroughbred Merino sheep and the Angora goat husbandry, importing from Asia Minor pure blooded Angoras for the late Hon. Richard Peters, of Atlanta, Georgia, Hon. E. B. Bigelow, of Boston, and others. While with the Wool Association, he was often in Washington, in the interests of protection and tariff matters.

His deep solicitude for the progress of the industries of the country led him to investigate the condition of affairs at the South, coming in contact with many prominent men of that section, and interesting himself in its growth and resources. As a result he believed in bringing northern and southern men face to face, and following this idea he was the principal agent in attracting Gen. Gordon to Boston, in 1878, where as will be remembered, a royal welcome was given, such as it was never dreamed northern men would accord to a southerner. The good to both sections can never be computed.

In 1878 Colonel Jenks engaged with the Brush Electric Light Co., doing pioneer work in Boston in the sale of the first commercial plant to the clothing firm of Freeland, Loomis & Co., and taking personal charge of the placing and operating of the Brush exhibit at the first Mechanics' Fair (1878), on the occasion of the memorable test when several learned scientific "experts" decided that a machine, of which it is said not another was made, was superior to the Brush. For about four years he worked early and late in introducing the Brush apparatus, thus assisting in laying the foundations of that enormous business, and the general industry of commercial electric lighting.

In 1882 he came to N. Y. as editor of the *Industrial Record*, filling that position with eminent ability, and to the satisfaction of the patrons of that journal. Active business being more to his taste than editorial duties, and preferring Boston for a home, he yielded to the importunity of a friend who was connected with the Standard Paper Bag Co., and accepted the management of that enterprise, only to see all destroyed by fire just as he had systematized the business. The company did not rally, and he next engaged with F. A. Lockwood of the Lockwood Mfg. Co., East Boston, in the interests of the Cape Cod Ship Canal Co. in 1884, rendering that corporation valuable services through his acquaintance with prominent men, and interesting in the plan such capitalists as General C. C. Dodge of this city.

In 1887 he came to New York with the Sprague Electric Railway and Motor Co., and in the infancy of the enterprise, put into the preparation of their advertising literature, and the development, amid many difficulties, of their Department of Mills and Mines, all the enthusiasm of his earlier years, and all the results of his long business experience and ability as a writer and correspondent. But unremitting and largely unrequited labor for many years had broken his strong constitution, and early in March he was suddenly missed from the office, and though apparently improving at the residence of his son—Mr. W. J. Jenks, of the Edison General Company—at Nyack on the Hudson, dropped without warning and lived scarcely an hour.

Colonel Jenks was a man of remarkable versatility. For years he has been recognized as the first living mining engineer in the department of corundum and its gems. He was often referred to in the literature of the textile industries as the best authority in America on Mohair and the Angora goat. He had within three years acquired an exhaustive knowledge of the commercial application of electric motors to mining operations, and his foresight and persistent effort brought about the invention by Mr. Edison of a percussion rock drill. As an editorial writer he had few superiors in his specialties, articles from his pen often finding their way even during the later and busiest years, into the technical journals of the textile and electrical arts. His command of terse vigorous English, in speaking as well as writing, was recognized wherever he was known. He was a patient and tireless worker, and his was throughout the life of a pioneer, sowing the seed of one enterprise after another, from which others reaped the harvest.

He was a recognized art critic, and was the means of encouraging and building up several of those whose names are well known as American painters. He was also an accomplished Bible scholar, and a course of lectures delivered 30 years ago was warmly commended by Wendell Phillips and others, and is even now referred to as unique and exceptionally instructive in its treatment of the history and customs of eastern lands.

He was ever a gentleman, courteous to all, and generous even beyond his means. His strong belief in the integrity and honesty of mankind often worked to his own disadvantage. He leaves a widow (a second marriage) and eight children, of whom five are sons in active business life, one having been identified with telegraph, telephone and electric light interests since 1872 and now connected with the legal department of the Edison Electric Light Co. in this city; another in the offices of the Sprague company; and two identified with the development of the real estate and mining interests of the South at Asheville, N. C.

...If we would judge fairly of the merits of a new invention we should not only look upon it by itself, but compare it with all that has gone before and might be superseded by it.—*Gisbert Kapp*

....It is a popular but erroneous belief that great inventions have sprung, full-grown and completely equipped, from the brain of their inventors, like Minerva from the brain of Jupiter.—*John Gray.*

....It is this peculiarity of electric transmission, that the power consumed is always proportional to the work performed, which renders it on the whole more economical than some other and purely mechanical devices.—*Gisbert Kapp.*

.... There are two troubles which beset most accumulators viz., buckling of plates and bad forms of sulphating. To these all other difficulties, with few exceptions, may be traced. Buckling is almost unknown in well-managed installations.—*Sir D. Salomons.*

....Without the use of hypotheses or antecedent probabilities as a general rule, no extended series of investigations can be made as to the approximate cause of casual phenomena. They require to be used, however, with great care, lest they become false guides which lead to error rather than to truth.—*Joseph Henry.*

LEGAL NOTES.

CIRCUIT COURT OF THE UNITED STATES— DISTRICT OF NEW JERSEY.

(April 12, 1890.)

THE HOLMES BURGLAR ALARM TELEGRAPH CO. AND THE MUNICIPAL DISTRICT TELEGRAPH CO. *vs.* THE DOMESTIC TELEGRAPH AND TELEPHONE CO., GEORGE W. HUBBELL, ENOS BUNYON, E. T. FEAREY, AND JABEZ FEAREY.

Wales—*J.* This suit was brought to restrain the defendants from infringement of re-issued Letters Patent No. 4,297 for improvements in electro-magnetic burglar alarms, granted March 14, 1871, to William B. Guernsey. One of the complainants is the owner of the patent, and the other is alleged to be a licensee under it.

The bill sets out the title of the Holmes Burglar Alarm Telegraph Company, and the granting of an exclusive license for certain purposes to the Municipal District Telegraph Company; but objection is made, in the answer of the defendants, that, in fact, no license was ever granted to the Municipal District company, and in consequence of the absence of joint interest and privity between the parties complainant. the bill should be dismissed on account of this misjoinder. Waiving a consideration of the question whether this objection should not have been taken by a plea in abatement, it is sufficient for the present purpose to say that the testimony of the witness, Holmes, and the written agreements in relation to the ownership and use of this patent, which are set out in the complainants' exhibits, afford satisfactory proof that a license was given to the Municipal District Company, as is alleged in the bill. The granting of a license may be proved by the acts and dealings of the parties who own and permit others to use the patent, without the necessity of resorting to written instruments, and it clearly appears from the proofs that prior and up to the time of bringing this suit, the Municipal District Company had been treated and acknowledged as its license by the owner of the patent. This inference of fact is drawn from the transactions which were had between the Holmes Burglar Alarm Company, and its immediate licensee, the Protective Company, which latter company transferred its license to the Municipal District Company. Admitting, as it is claimed by the defendants' counsel, that the license to the Protective Company was personal only, and not transferable, and that it had not, prior to its assignment to the Municipal District Company, any right to assign its license, yet it is certain that the Holmes Burglar Alarm Company acquiesced in and ratified the assignment, and thereafter recognized the Municipal District Company as its licensee. There is no restrictive provision in any of the agreements which prevented the owner of the patent from conferring authority on the Protective Company to assign its license, and such authority may be proved without the aid of written articles. This conclusion dispenses with the necessity of discussing the regularity of the mode adopted by the defendants in presenting the objection of misjoinder, which, under the technical rule of pleading and Equity Rule 39, should have been taken advantage of by a plea in abatement.

Another preliminary objection, which is insisted on by the defendants' counsel, is that claim 2 of the original Guernsey patent, which is made claim 4 of the re-issue, is not covered by the oath of the inventor, and is therefore a nullity, and forms no part of the real patent. There is no evidence on this point, and there is equal ground for the presumption that the oath was taken as that it was not. But is the taking of the oath absolutely necessary? In *Whittemore v. Cutter*, Judge Story said, "the taking of the oath was but a pre-requisite to the granting of the patent, and in no degree essential to its validity." In *Crompton v. Belknap Mills* (3 *Fisher*, 536), the defendants, as in the present case, relied upon a certified copy of the file-wrapper and contents, to show that the oath had not been taken, but the Court said:

> We are not satisfied that the oath was not taken. The letters patent recite that it was. * * * "But suppose the oath was not taken; would the patent be void on that account? It was held otherwise by Judge Story. The taking of the oath, though to be done prior to the granting of the patent, is not a *condition precedent*, failing which the patent must fail. It is the evidence required to be furnished to the Patent Office, that the applicant verily believes he is the original and first inventor, etc. If he takes this oath, and it turns out that he was not the first inventor or discoverer, his patent must fail and is void. So, if he do not take it, still if he is the first inventor or discoverer, the patent will be supported.

It has also been held that this is not a matter to be inquired into collaterally in the infringement suit. Hoe *vs.* Kahler (20 Blatch. 430); De Florez *vs.* Reynolds (14 Blatch. 505); and in Railway Register Co. *vs.* North Hudson Co. the Court recognized the right of an applicant's attorney to insert in a pending application amended and enlarged claims "without having them verified by the oath and signature of the patentee provided only they relate to matter substantially shown and described in the specification." As to the oath it was decided in Seymour *vs.* Osborne (11 Wallace, 516), that recitals in letters patent that the required oath was taken before the same was granted, are, in the absence of fraud, conclusive evidence that it was so taken.

Original letters patent No. 103,257 were issued to Guernsey, October 11, 1870, and the re-issue for the same invention No. 4,297 were granted to him on March 14, 1871. The nature and objects of the invention are, in part, thus specified by the patentee, in the re-issue:—

> *The principal object of my invention is to provide an electrical apparatus which will give an alarm or an indication either in the event of the conducting circuit being broken or in the event of a new or shorter circuit being formed.* To this end I employ a continuous circuit or a circuit capable of being made continuous at will, arranged with *a resistance* or resistances, so that the current which is allowed to pass will not possess sufficient E. M. F. to effect the alarm, but having such arrangements at windows and doors and other places to be guarded as will, on any tampering therewith, short-circuit the currents past or around the said *resistance* or resistances to an extent sufficient to actuate the alarm. My invention thus combines the advantages and avoids the disadvantages of the two varieties of electro-magnetic alarms which are distinguished as the closed-circuit system and the open-circuit system.
>
> *I will proceed to describe a way of carrying out my invention by the use of two separate electro-magnets, each of which may constitute a resistance to prevent the sounding of an alarm until the circuit is either made around or past such resistance or broken. More than one magnet or resistance is not essential in carrying out the invention, as will be understood from the following explanation*:
>
> Fig. 1, shows, in perspective, two electro-magnets with separate conductors connected with a common battery. each conductor passing through an alarm, and through suitable connection devices, which may be located in the frames of windows, or at any desired points, in such manner that the opening of a door or window, or the performance of any act which it is desired to detect, will connect one conductor and avoid both electro-magnets. For this purpose the magnet of one conductor is located near the positive pole, and that of the other near the negative pole of the battery.
>
> Fig. 2, illustrates a modification, in which one magnet *may be* dispensed with and a simple resistance coil introduced *at the point to be protected* in such a manner that the act to be detected will close a short-circuit avoiding the resistance and thus sounding the alarm. This more simple form of the apparatus is applicable to places where a single window, door, or other object is to be protected.

Then follows a general description of the drawing.

> *Two magnets and two conducting wires are shown and described, but only one magnet or other electro-motor and one conducting wire is necessary to accomplish the same effect as will be manifest by an examination of the arrangement and a knowledge of the principles involved. The location, with regard to each other, of the various members or elements of the alarm is not an essential part of the invention and can be varied as circumstances dictate.*
>
> Where but a single place is to be protected, as, for example, for the vault-door of a bank, the apparatus may be simplified, dispensing with one of the resistance magnets and employing a simple resistance R, Fig. 2, *placed at the point to be protected*, and so arranged *with regard to the other members of the alarm* that the opening of the door or window, or the doing of any act which the alarm is to detect, will short-circuit the conductor by forming a connection between the wires, across or independently of the resistance.
>
> Various other modifications will readily suggest themselves for the accomplishment of the object without departing from the essential principles of the invention, the design being to obtain an alarm in which the signals shall be given by the closing or making of connection between two different conductors, or between two parts of the same conductor *essentially* as is done in the open or interrupted circuit alarms, while at the same time there is or may be a continuous circuit in the said conductor or conductors, which, by proper contrivances, may be made to give notice to the person in charge of said alarm of any injury, accidental or malicious, which may have happened to his instrument or its belongings.

The third and fourth claims of the re-issued patent are precisely identical with the first and second claims of the original patent, with the exception of the italicized words which have been inserted in the re-issue, and are as follows:—

> 3. The combination in an electro-magnetic alarm, of a continuous circuit or circuits, with a sufficient resistance or resistances, and an alarm or alarms, when the said combination is so arranged that the severing or interrupting of the said circuits, or of either of them, shall cause the said alarm or alarms to sound; and also, that the short-circuiting or diverting the course of the electrical current in said circuit or circuits around *or* past the said resistance or resistances shall sound an alarm, *or cause an alarm to be sounded*, this when the whole arrangement is properly combined with a sufficient battery, and with "connections" or contrivances at points to be guarded, which will, upon the doing of certain acts, or the happening of certain things, short-circuit the said electrical current or currents past or around the said resistance or resistances, and so give the desired alarm.
>
> 4. In a burglar or fire-alarm, the combination of an open and a closed circuit to operate substantially as set forth.

The third and fourth claims of the reissue have not been enlarged, and are identically the same with the first and second claims of the original, with the exception of the italicized words in the former which do not materially change their effect. The drawings accompanying both patents are the same. The specifications in the reissue are the same as in the original, excepting the italicized portions, and describe the nature and objects of the invention more clearly and plainly than is done in the latter, in order to cover any element to which, by a fair construction of the original, the patentee would have been entitled; and for this purpose a reissue has always been allowed when the patentee has, by inadvertence or mistake, omitted to make such a description in the original. A patentee can claim on a reissue whatever clearly appears to have been a part of his original invention as described or shown in his original specification, drawings or models, and Guernsey has done no more. *Battin v. Taggert* (17 How. 74); *Gallahue v. Butterfield* (10 Blatch., 232); *Wheeler v. Clipper Co.* (6 Fisher, 1); *Seymour v. Osborn* (11 Wall, 544); *Colkins v. Burtrand* (6 Biss., 494); *Russell v. Dodge* (93 U. S., 460).

The two prior systems referred to by the patentee were well known at the date of the patent, and had been in extensive use, but each had certain serious and recognized defects which it was the object of Guernsey's invention to obviate. The advantages and disadvantages of the old systems are thus stated by Professor Brackett:—

> The advantage of the open-circuit system is, that the apparatus cannot be disabled by connecting the two parts of the circuit together between the battery and the point protected, since such connection would sound the alarm in the same manner as opening the door or window. The disadvantage of this system is, that the circuit may be cut out or disconnected at any point without sounding the alarm, and this would completely disable the apparatus, since no alarm would be given upon a subsequent opening of the door or window. Such a system offers no difficulty to a burglar, except as the wires leading from the battery

> to the protected structure be effectually concealed, which might be difficult to do.
>
> The advantage of the closed circuit system is, that the line is protected against cutting or interruption, since such an act would sound the alarm, and its disadvantage is, that it may be completely disabled by forming a short circuit around the point protected, since this would not sound the alarm, nor would the alarm be sounded by any subsequent opening of the door or window.

It is thus apparent that each of these prior systems afforded sufficient protection as long as the wires or conductors remained intact, but both were fatally defective in that they could readily be disabled by tampering with the wires; and it was the object of the Guernsey invention to protect the wires or conductors from being tampered with, by any method applicable to either of these systems.

Mr. Pope thus states the general nature of the invention:—

> Guernsey was the first, so far as I am able to ascertain, from the evidence in this case or otherwise, to combine in one and the same organization of circuits, the characteristic signal instruments of both the open-circuit system and of the closed-circuit system with a resistance or resistances, in such a manner as to make the open-circuit instrument guard against disabling the apparatus by any method applicable to the ordinary closed-circuit system; and conversely, to make the closed-circuit instrument guard against disabling by any method applicable to the ordinary open-circuit system.

Both complainants and defendants are engaged in the business of central office protection, and, as it is alleged, make use of almost identically the same form of apparatus.

The defendants' apparatus consists of a battery, two principal instruments and their accessories, conductors connecting the battery and instruments with an electrical casing enclosing a safe, a resistance and contact-springs connected with the door of the safe-casing. Both instruments are included in the circuit, so that the current traverses their coils successively. One of them, designated as the "galvanometer" in the drawing (Complts. Exhibit No. 6), consists of a magnetized needle pivoted so as to swing freely in either direction in front of a coil through which a current passes. Its movement is limited by contact-stops, which form the terminals of a local circuit containing an alarm-bell B. The instrument is so constructed and adjusted, that when the resistance at the safe is included in the circuit, the needle stands between the two stops, but when the current is strengthened by short-circuiting the current past or around the resistance, the needle is swung, by the influence of the current in the coil, against the stop at the right, and an alarm is sounded on the bell B. It thus performs the function of the ordinary open-circuit instrument. In addition to this, when the circuit is broken, the needle swings against the stop at the left and rings the same bell. The other principal instrument, designated as a "relay" in the diagram, corresponds in all respects in construction and mode of operation to the ordinary closed-circuit instrument. By the intervention of two local circuits, it is made to release a drop or shutter and ring an alarm-bell C, when the current ceases to flow through its coils. There are two sets of contact-springs at the safe, so arranged that upon the first movement of opening the door, the circuit is broken at the springs J J' at the top, and an alarm is sounded upon both the bells B and C; upon opening the door a little farther, a short circuit is formed around the resistance coil R, through the wire G G, and the galvanometer swings to the extreme right and again rings its bell B. If any attempt is made to tamper with the apparatus by cutting either of the wires leading to the safe, an alarm is sounded both upon the galvanometer-bell B and the relay-bell C; and if the wires are short-circuited, an alarm is sounded on the galvanometer-bell B.

It is contended, on behalf of the complainants, that the defendants' apparatus, the operation of which is thus described, contains the gist of the Guernsey invention, since it contains instruments having the characteristic mode of operation of the instruments of the two old systems referred to in the patent, and these are combined in the same circuit with a resistance so arranged as to render both instruments operative. The result of this combination is, that the wires leading to the safe are effectually protected both from interruption and from short-circuiting. In other words, the same result is produced by substantially the same means in defendants' apparatus as in the apparatus of the patent.

It is conceded that the use of a galvanometer-needle, such as used in the defendants apparatus, to open and close a local circuit, including an electric bell, was well known in the art prior to the date of the patent, and that the galvanometer was recognized as an equivalent, for that purpose, of an electro-magnet and armature such as is shown in the patent. It is urged by the defendants that the galvanometer is made to perform an additional function in their apparatus, but this fact will not relieve them from the charge of infringement, so long as all the elements of the complainants' patent are embraced in their system. *Williams v. Barnard* (41 *Fed. Rep.* 364.)

A careful examination of the testimony, which displays a special knowledge of the art united with unusual intelligence and ability on the part of the witness, leaves no doubt that the defendants are infringers of the third and fourth claims of the reissued patent. An elaborate review of the testimony with references to the numerous models and diagrams contained in the exhibits, would extend this opinion to an unreasonable length, and under the circumstances of the case is not necessary.

The validity of the reissue was vigorously attacked on the ground of its alleged variances from the original patent, and chiefly because the latter does not contain even a suggestion of a single-circuit form of apparatus; but a comparison of the specifications and drawings of the two patents does not sustain this objection. Fig. 2, in the drawing of each patent, shows a single wire, and if by mistake or accident the original specification did not describe with sufficient plainness the use and application of this wire, it was permissible to the patentee, under the provisions of the Act of Congress relating to reissues, to supply the omission as soon as it was discovered, and this he did within a few months after the date of the original. The single circuit was clearly indicated in the original, and by a fair construction the patentee would have been entitled to its use. As already shown, the claims in suit were not enlarged in the reissue. In fact the fourth claim is restricted, by the words "to operate substantially as set forth."

It is further insisted on by the defendants, that the patent in suit does not contain a patentable combination, in that it is only an aggregation of old parts of elements, which act successively and not simultaneously.

The simultaneous co-operation of the parts is not essential to a patentable combination if the parts are so arranged that the successive action of each contributes to produce some one practical result, which result, when attained, is the product of the simultaneous or successive action of all the elementary parts, viewed as one entire whole. The term co-operation does not mean acting together or simultaneously, but unitedly to a common end. *Birdsall v. McDonald* (1 *B. & A.* 165); *Forbush v. Cook* (2 *Fish.* 668); *Hoffman v. Young* (2 *Fed. Rep.* 77). So here, the electrical protection of the conductors is the result produced by the combination, and the two instruments guard the same line at the same time. One instrument protects it from cutting and the other from short-circuiting. Remove either instrument and the result fails *pro tanto*. This result was useful and never before known. The design of the combination was to protect the patented apparatus against the methods of disabling it, by tampering with the conductors, as could be done with the prior systems. The instruments co-operate in making good each other's deficiencies, and the arrangement of the conductors is such that all their essential parts are brought under the protection of the instruments. To this end the resistance co-operates with the closed-circuit instrument by forming a path for the current when the apparatus is in its normal condition, so that a continuous current may flow through the conductors and through the instrument without giving an alarm; it co-operates with the open-circuit instrument by enfeebling the current to such an extent that the open-circuit instrument is not called into action until a short circuit is formed, and the current thereby increased. In view of the authorities, this constitutes a patentable combination, leading to a new result by new means.

But the defendants have introduced certain prior English patents, which, they say, embrace substantially the same elements as are found in the patent in suit and thus deprive Guernsey of the claim of originality. It is not asserted that the inventions contained in the English patents are identical with that of the Guernsey patent, but that in the state of the art at the date of the Guernsey original patent, it required only simple modifications and substitutes in the English devices, to make them produce the same results as are secured by the Guernsey combination. The English patents referred to are those of Tyer (1865), Varley (1865), and Moxon (1266). The device of Tyer is an apparatus for transmitting signals indicating the position of trains upon a railway, and his patent contains no suggestion that it could be adapted to perform the office of a burglar-alarm; it can be easily disabled by cutting one of its wires, and is thus incapable of effecting the result secured by the Guernsey invention, which is the electrical protection of all parts of the conductors between the signal-instruments and the points to be protected. The Varley apparatus is a modification of the ordinary closed-circuit system, and does not contain any instrument corresponding to the signal instrument of the open-circuit system, or any other means of giving an alarm which is operated by an abnormal strengthening of the current, nor does it contain a resistance separate and distinct from the instruments; and it can be entirely disabled, if used for central-office protection, by inserting a battery in some part of the line leading from the circuit-closer to the alarm instrument. The Moxon patent would also require substantial alterations to make it accomplish the results which are obtained by the Guernsey combination.

The proposed modifications and substitutions would be in the nature of invention, and are not such as would readily occur to any one skilled in the art. They do not consist merely in the substitution of one known equivalent for another without any change in the resulting mode of operation, but it is proposed to substitute for one or the other of the elements of the prior combination something having a different or additional function, which amounts to the same thing as adding to the combination a new and distinct instrument, and makes it a new combination having functions that it did not before possess. Defenses of this character have been frequently discountenanced by the courts. *Wooster v. Black* (8 *Fed. Rep.* 429); *Dudgeon v. Watson* (29 *Fed. Rep.*

248); *Asmus v. Alden* (27 *Fed. Rep.* 684). Here, as in *Dudgeon v. Watson*, the defendants had used practically the same combination as is covered by the Guernsey patent, and subsequently made the changes by which they sought to escape infringement, but in that case the Court held that the defendants accomplished the same result by similar or equivalent means.

Among other objections to the Guernsey reissue it was urged that no interference was had between the reissue application and the Holmes & Roome patent of December 20, 1870; but there is no proof that Holmes & Roome were the prior inventors; on the contrary, the invention claimed in the Guernsey reissue was shown and described in the Guernsey original patent, which ante-dates any date of Holmes & Roome. The English patent, to Holmes & Roome, although dated as of November 1, 1870, was not in fact issued until April 2, 1871; the date at which the great seal was attached, and therefore the provisions of section 4,887 of the United States Statutes do not attach to the corresponding patent issued by the United States. The English patent to Holmes & Roome not being sealed, was not in existence until after the date of the Guernsey patent. *Gold & Stock Tel. Co. v. Commercial Tel. Co.* (23 *Fed. Rep.* 340).

The able and ingenious argument of defendants' counsel created, at first, some doubts of the validity of the Guernsey reissue, but after a careful consideration of the various objections presented by him, both orally and in his printed briefs, the conclusion has been reached that Guernsey was the original inventor of the combination claimed by him, and that the reissued letters patent are valid. A decree will be entered for the complainant, excepting as against the individuals named as defendants, in relation to whom there is no proof that they were personally guilty of infringement.

PATENT OFFICE INTERFERENCE.

EX-PARTE MEUCCI.

In the case of *ex-parte Meucci*, decided March 26, it appears that Antonio Meucci filed an application December 8, 1883, for a patent for a sound telegraph which was in fact a speaking telephone. It was proved that in 1871, a caveat had been filed by the applicant which was claimed to exhibit the invention embraced in the application, which caveat was renewed in 1872 and in 1873, and was then allowed to lapse. The case came up on a motion for rehearing, applicant averring that in the former decision of Commissioner Hall, he had erroneously held that applicant was barred by two years' public use prior to this application; that such public use had been established, and was in error in not passing Meucci's application to patent, so that an interference might be declared therewith. Commissioner Mitchell held that a caveat is not an "application" within the meaning of the statute; that the primary examiner was right in taking judicial notice of the fact that the telephone had been in public use more than two years prior to December 8, 1883, and that no attempt had been made by the applicant to disprove the fact; and that there is no statute authorizing an interference where the application of the party demanding such interference has been rejected by the primary examiner and the examiners-in-chief. The motion was accordingly denied.

GREAT WESTERN TEL. CO., E. R. BOWEN, RECEIVER, VS. HIRAM PURDY.

The case of the Great Western Telegraph Company, E. R. Bowen, receiver, vs. Hiram Purdy, was decided in the District Court, Burlington, Ia., on April 19. This case is of great importance to many citizens of Iowa. In 1867 to 1869 many citizens of the State subscribed to the capital stock of the company, or at least believed they so subscribed from the representations made to them by the agents at the time. The company soon thereafter contracted a large indebtedness and being insolvent passed into the hands of a receiver in 1874. In 1886 an assessment of 35 per cent of the stock was made by the court at Chicago, and the receiver brought this, the first action in Iowa to collect the amount. The intention is to sue all the subscribers in Iowa. There were many defenses pleaded and the issues involve many intricate questions of law. Judge Phelps gave the case a thorough consideration and decided in favor of the defendant. The case will probably be taken to the Supreme Court as a test case by the receiver.

THE WESTINGHOUSE ELECTRIC RAILWAY COMPANY.

The following is the circular now being issued by the above company, announcing its appearance in the field. It bears the signature of Mr. H. McL. Harding:—

We especially desire to call your attention to the Electric Railway System of the Westinghouse Electric Railway Company of Pittsburg, Pennsylvania. This system consists of constant potential dynamos and motors of five hundred volts, by the overhead method, and includes all the latest and most improved devices, many of which are peculiar to this company. There are no radical departures from the existing methods of electric street car propulsion, but great improvements in the details of mechanical construction and workmanship, the superiority in this branch of manufacture is the result of many years' practical experience in the building and operating of electric plants in every section of the country, and this experience of the companies allied to and controlled by the Westinghouse Electric Company, such as the United States, Sawyer-Man, Consolidated Electric Company, dates back as far, if not farther, than any companies now in the field constructing electric machinery. In addition to this the reputation of all work turned out by the Westinghouse Company for the best mechanical construction is so well known as not to need repetition here. One well-known street railway president said: "If George Westinghouse is going to build motors for street railway work, we can feel confident that the practical mechanical workmanship will be what has been so desired by street railway men. In most of the roads I have examined there has been a criminal negligence in this respect." All parts of the motors are made exceptionally strong, the bearing and working parts of great width, in short the strength of all parts conduce both to durability and the absolute certainty of regular daily operation.

The question of insulation has also received great attention and the perfection that has been attained by the Westinghouse Company in the manufacturing of their alternating dynamos in this respect, which from the peculiarity of the alternating current requires far greater skill than the direct current, is a guarantee in itself that this important feature is all that can be desired.

This company is not connected with any trust or combination of companies, and is able to quote you prices on whatever dynamos, motors or line material you may require, and promises in advance that the prices will appeal to you as being fair and just. Mr. H. McL. Harding, formerly General Agent of the Sprague Co., Mr. J. L. Barclay, the Western Representative of the same company, and Mr. C. C. Warren, District Manager of the Edison Company, are associated with this company.

The Westinghouse motors can be operated on any existing lines of electric street railways and the dynamos in connection with those already installed. The company are now ready to deliver motors and dynamos promptly after the orders are given, and will guarantee their machinery in every particular.

INVENTORS' RECORD

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued April 22, 1890.

Alarms and Signals:—*Bell and Engine Indicator for Pilot Houses of Steam Vessels*, W. E. Hadlock, 426,009. *Electric Signaling Apparatus for Hotels*, J. J. Miller, 426,134. *Thermostat*, J. P. McMahon, 426,304. *Electric Annunciator-Call*, W. S. Paca, 426,307.

Conductors, Insulators and Conduits:—*Insulated Joint*, E. F. Gennert, 426,121. *Apparatus for Hauling through Electric Cables*, J. F. Munsie, 426,196. *Underground Conduit*, J. F. Munsie, 426,197. *Insulator*, J. F. Munsie, 426,198. *Duct for Electric Conductors*, J. F. Munsie, 426,199. *Flexible Connector*, J. F. Munsie, 426,200. *Insulating Lining*, J. F. Munsie, 426,201. *Insulating Compound*, J. F. Munsie, 426,202. *Insulator*, J. F. Munsie, 426,203. *Binding Post*, J. F. Munsie, 426,204. *Duct for Electric Conductors*, J. F. Munsie, 426,205. *Man-Hole for Underground Electric Conductors*, J. F. Munsie, 426,206.

Distribution:—*Safety-Connection*, E. Thomson, 426,082. *System of Electrical Distribution*, C. J. Kintner, 426,127. *Converter*, E. Wagemann, 426,153.

Dynamos and Motors:—*Electric Machine for Covering Wire, &c.*, F. E. Davis, 425,990. *Electric Motor*, F. E. Davis, 425,991. *Safety Device for Dynamos*, E. P. Clark, 426,108, 426,109 and 426,110. *Dynamo Electric Machine*, M. J. Wightman and E. Thomson, 426,348. *Electric Motor and Dynamo*, J. C. Henry, 426,380.

Lamps and Appurtenances:—*Incandescent Electric Lamp*, J. W. Packard, 426,055. *Electric Lamp Hood and Support*, E. P. Warner, 426,155.

Measurement:—*Current-Indicator*, F. B. Rae, 426,065. *Armature for Electric Meters*, O. B. Shallenberger, 426,335.

Miscellaneous:—*Electric Fan*, P. Diehl, 425,995. *Magnetic Circuit-Closer*, J. von der Kammer, 426,021. *Electric Switch*, J. P. Norton, 426,049. *Fuse-Block*, T. Patterson, 426,057; *Fuse Block*, F. G. Warrell, 426,156. *Lightning Arrester*, A. D. Spear, 426,338. *Electric Gas Lighter*, C. H. Hinds, 426,381.

Railways and Appliances:—*Trolley-Support*, F. B. Rae, 426,066. *Electric Railway Contact*, F. O. Blackwell, 426,102. *Electric Railway System*, L. Gutman, 426,269. *Coupling for Electric Cars*, L. Pfingst, 426,317. *Electric Railway Car*, J. C. Henry, 426,379. *Electric Railway*, R. M. Hunter, 426,382. *Apparatus for Electric Railway Signaling*, C. H. Rudd, 426,395.

Secondary Batteries:—*Process of Manufacturing Electrodes for Secondary Batteries*, L. Epstein, 425,999.

Telegraphs:—*Electro-Magnetic Instrument*, P. B. Delany, 426,247.

Telephones and Appliances:—*Coin-Controlled Apparatus for Telephones*, W. Gray, 426,266.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

ANOTHER SOUTHERN SPRAGUE ELECTRIC RAILWAY.

We note with interest in a list of recent Sprague railway contracts furnished us by the Sprague Electric Railway and Motor Co. that a number of these come from Southern States.

This portion of the country has been up to this time rather slow in adopting methods for street railway propulsion, but the fact is evident that this slowness is growing less continually. One of the largest of these contracts made by the Sprague company is that with the Augusta Street Railway, the principal street railway in Augusta, Ga. The equipment of this road, which will be in operation before very long, will be first class in every respect. The cars to be equipped with electric motors are 16 in number, and each will carry two 15 h. p. motors. At the station, the generating plant will consist of two 30,000 watt dynamos for supplying the necessary current for the line, which will be more than 15 miles in length. The line of route passes the Union Depot, Opera House and the principal points of interest in the city.

After leaving the heart of the city, the street car tracks are laid in the centre of the boulevard in the residential districts in which the roadway lies on each side.

The centre strip, which occupies a space of 60 feet between the roadways, contains a double row of large elm trees running the entire length of the boulevard, so that the poles required for span work are almost entirely hidden by the foliage, and are so rendered unobjectionable even to the most critical eye. The space between the tracks will be covered with turf, so that the tracks will not be noticeable at a little distance. It is hoped that 5 cars will be in operation by May 15, and the rest of the equipment will be in operation by June 15.

INSTALLATIONS OF C. & C. MOTORS.

The C. & C. Electric Motor Company, of 402 Greenwich st., this city, have to report the following sales: Edison Electric Illum. Co., Brooklyn, one 3 h. p. for ventilating station and one ⅛ h. p. fan outfit; one 1 h. p. to Pennsylvania R. R. shops, Altoona, Pa.; one 10 h. p. to American Press Association, Chicago, Ill.; one 1 h. p. to Messrs. Gahl & Lembke, 21 Union sq., New York; one 2 h. p. to T. H. Porter, Stamford, to run elevator; one 2 h. p. to Edison Electric Illum. Co., Newport, R. I.; one 10 h. p. to *Sunday Telegram*, Harrisburg, Pa.; one 1 h. p. to First Presbyterian Church, Easton, Pa.; one 1 h. p. to J. H. Simpson, 154 W. 23d st., N. Y., to run ventilating fan; one 3 h. p. to Edison Electric Illum. Co., 432 Fifth ave., N. Y.; one 8 h. p. to the Solomon Lord building, 18th st. and Broadway, running elevator; one 1 h. p. to Thompson's, 25 East 14th st., N. Y., running ventilating fan; one 1 h. p. to Warren & Witherell, 201 Hanover st., Boston, Mass., to run coffee grinding machine; one 2 h. p. to St. Thomas' Church, 53d st. and Broadway, N. Y., to run ventilating fan; one 1 h. p. to Edison Electric Illum. Co., Fall River, Mass.; one 1 h. p. to C. M. Gage, Champion Card and Paper Co., Pepperell, Mass.; one 5 h. p. to Fletcher & Co., Portland, Me., to run elevator; one 5 h. p. to Dr. Kilbourne, pres. of Seattle Electric Railway & Power Co., Seattle, Washington; one 2 h. p. to Ryan Bros., Appleton, Wis.; one 1 h. p. to *Court Journal* Publishing Co., 608 F. st., Washington, D. C., to run press; one 2 h. p. motor to B. F. Robinson, 21 Broadway, Lawrence, Mass., to run lathe; one 5 h. p. to Fell & Josephs, Wilmington, Del., to run elevator; one 4 h. p. to Bradley Fertilizer Co., North Weymouth, Mass.; one 4 h. p. to Allen & Kenway, 220 Devonshire st., Boston, Mass., to run ventilating blower; one 2 h. p. to Howard & Co., 264 Fifth ave., N. Y., to run jeweler's lathe and polishers; one 1 h. p. to Trinity Church, Easton, Pa.; one 3 h. p. to Whiting Mfg. Co., Union sq., N. Y., to run jeweller's lathe and polishers; one 4 h. p. motor to Professor C. A. Young, Halsted Observatory, Princeton, N. J., to turn observatory dome; one 5 h. p. to Fraser & Chalmers, Salt Lake City, Utah, to run a dynamo; one 3 h. p. motor to Leighton & Wilson, Phœnix building, Salem, Mass.; one 2 h. p. motor to Kobe, Japan; one 5 h. p. motor to G. B. Grant, 137 Franklin st., Boston, Mass.; one 15 h. p. motor to Snyder & Black, 92 William st., N. Y., to run lithographic and printing presses; one 1 h. p. to Wickstead Umbrella Co., 47 John st., N. Y., running machine shop; one h. p. to Church of Holy Communion, 6th ave. and 20th st., N. Y.; one 3 h. p. and one 10 h. p. to W. R. Danderson, 194 Water st., N. Y., running printing presses; one 10 h. p. to Trask Milling Machine Co., 118 South st., Boston, Mass., running machine shop; one 1 h. p. Southern District Telegraph and Electric Co., Birmingham, Ala., to run printing presses; one 1 h. p. to Roanoke Electric Lt. and P. Co., Roanoke, Va., used in printing the *Roanoke Daily Herald;* one 1 h. p. to General Society of Mechanics and Tradesmen, 18 E. 16th st., N. Y., to run ventilating fan; one 1 h. p. to St. John's Church, Reading, Pa.; one 15 h. p. to William Silverman, The Wire Buckle Suspender Co., Williamsport, Pa., to run shop; one 5 h. p. motor to John J. Tuomey, Jackson, Mich.; one 15 h. p. to W. W. Bullock, Wilmington, Del.; one 3 h. p. to D. P. Gosline, 32 Oliver st., Boston, Mass., ventilating fan; one 15 h. p. motor to Queen City Electric Light Co., Gadsden, Ala.; one 1 h. p. to Silvey Electric Co., Lima, O.; one 2 h. p. motor to Meyer, Singer & Co., Lycoming Pants Factory, Williamsport, Pa., to run sewing machines; one 4 h. p. to D. Coughlin, 5 Mill st., Lawrence, Mass., to run 28" saw; one 1 h. p. motor to Trinity Episcopal Church, west Fourth st., Williamsport, Pa., to run organ bellows; one 7 h. p. motor to Mercantile Printing Co., Wilmington, Del., to run presses; one 20 h. p. motor to Perry Woodworth, Smith building, Cincinnati, O.

THE COMING OF AGE OF AN ENGINE COMPANY.

The interesting fact that the New York Safety Steam Power Company, of 30 Cortland street, comes of age this year, has not received the attention it deserves in mechanical and engineering circles. The mere fact that a concern had withstood for twenty odd years the stress and strain of competition, in America, in one of the fields of hottest struggle and most rapid development, would of itself be cause for at least passing comment and congratulation. In the present instance there is to be borne in mind the further fact that the company, so far from resting upon its achievements, is in the full swing and brimming tide of activity and prosperity.

The explanation of such staying powers is to be looked for, of course, partly in the excellence of the product, and, to no small degree, in good business and technical management. Withregard to the engines themselves, of which some 50 types are now built and carried in stock, the records in the possession of Mr. E. T. Copeland, the general agent, show that 6,000 have been sold. These, averaged at 50 h. p.—the general run being now above that figure—would represent the magnificent total of 300,000 h. p. Some of the customers have bought the engines with an avidity that apparently nothing could satisfy, and one appears on the books as purchaser of no fewer than 62, up to February, 1889, since which time it has gone on buying as eagerly as ever. The big Cambria Iron Company, of Johnstown, Pa., had bought some 40 up to the time of the great flood. The engines in both instances are of the company's celebrated vertical type, ranging up to 30 h. p.

As is well-known, however, Mr. Copeland has of late years studied the developments of the electric lighting business very closely, and hence these figures are much more than paralleled by some of those furnished by that branch of industry. With one system alone, coming down no later than the early part of 1889, he had considerably over 100 engines in operation, many of large horse power; and the figures with other systems are in comparison and equal. Every one knows the exacting requirements of dynamo operation, in close regulation and smoothness of running, and it will be seen that these are squarely met when we state that a large proportion of the 50 engines put out by the factory, one week during this month—between 2 and 50 h. p.—were called for by electric light and power plants.

The development of electric lighting and power, and of the high speed automatic engine of to-day have gone on together, but Mr. Copeland considers that the point has about been reached when a fresh departure may be looked for, and when the work of engine building for electrical plants may soon be expected to lie along new lines. In some respects, he deems the more recent work to be purely experimental, and in others that the data as to the actual necessities is not yet all to hand. But so far as the work has gone, the New York Safety Steam Power Company has been prominent in it and actively engaged at the front; and it reaches its majority ripe in experience, rich in ideas, and ready for all that lies before in yet untried and even larger fields of usefulness.

THE MASSACHUSETTS ELECTRICAL ENGINEERING COMPANY.

The Massachusetts Electrical Engineering Company, formed a few months ago to do general electric engineering work, has been steadily increasing its business. Several tests have been made on street railroads, new dynamos, motors, telephone cables, etc., the results of which go to show the advantages derived by those interested from tests made by unprejudiced but competent engineers. In the line of constructive engineering, the company have been equally successful and busy, particularly in the direction of electric power transmission. On account of the large business which has so rapidly developed, the direction of their various interests has been further systematized by the formation of the following five departments: the Engineering, the Supply, the Testing, the Patent, and the Exporting Departments. The Engineering Department gives disinterested advice upon all electrical matters, designs and estimates upon electric lighting and power plants, obtaining bids for the same from the various electric companies. It also furnishes engineers to superintend construction or installation, its position toward its clients being similar to that of an architect towards his. The Supply Department manufactures and sells such electrical goods as from time to time are found necessary or advisable to place upon the market. It aims not to compete so much in price with other dealers as in trustworthiness. Having, as it does, the valuable assistance of the Testing Department, it can hardly fail of marked success in this direction. The Testing department does testing work of every description, calibration of instruments, etc., and furnishes, when desired, certificates of tests made on apparatus or devices. The Patent Department investigates and negotiates patents. The Exporting Department carries on a general engineering business with the West Indies, South America, etc. Mr. Charles A. Stone and Mr. Edwin S. Webster are the managers of the company, and Mr. Francis R. Hart the manager of the Supply and Exporting Departments. Their office and testing rooms are at 4, Post Office Square, Boston.

THE HALL CIRCUIT BREAKER.

MR. GEORGE L. HALL, of the Lowell, Mass., electric light station, has just designed an apparatus intended to prevent accidents due to the breaking of a wire on high tension circuits, by the latter coming in contact with metallic roofs or with persons and animals. According to the Lowell *Times*, the apparatus consists of two parallel steel flat bars or levers, broken in the middle and arranged with one piece of each over-lapping the other. These bars are fastened at each end to brackets by a lever joint. They are so insulated as to prevent any electrical connection between them and the whole machine is inserted into the circuit at the station near the dynamo. The current passes out from the dynamo through one of the bars over the circuit of lights and back through the second bar to the dynamo, completing the connection. Ordinarily, on account of the break in each bar, they would fall apart and cut the dynamo off from the wire and lights outside the station, but the first connection between the dynamo and the bar is made through a very powerful electro-magnet which acts when the current is complete and keeps the bars in place, the first half of each lapping under the second. It will be seen that in order to charge the electro-magnet and make it effective the circuit must be complete. The moment that a wire is broken at any place, the circuit is destroyed and the magnet, losing its powers, lets the bars fall apart and renders the entire line outside the levers harmless. The bar in falling starts a large electric bell ringing and calls the attention of the station to the break.

PROGRESS IN ENGINE BUILDING.

Electric lighting has probably had more influence on steam engine building in recent years than all other industries combined, and the experience already gained is making itself felt in various directions. After numerous experiments the Armington & Sims Engine Co. have arrived at the conclusion that the greatest economy in every direction can be gained from the double high pressure compound engine, and they propose to devote considerable attention to this type in the future. The merits of this engine combination are also being recognized by the managers of electric light and power stations. Thus, four of these engines of 250 h. p. each are now installed in the power station of the West End Street Railway Co., of Boston, Mass., and a contract has been entered into with the Boston Edison Co., to furnish 600 h. p. from their electric light station, which is also equipped with Armington & Sims' engines.

MORE ABOUT CONSOLIDATION.

With regard to the remarkable dispatch from Haverhill, referred to recently in our columns, the Lynn *Item* says very pithily:—"The *Item*, and Lynn stockholders in general, are fully satisfied with the Thomson-Houston management, and whatever may be done relative to the interests of that company will not effect such an ending as will discriminate between the large and small shareholders of the Thomson-Houston stock. Still another matter worthy of consideration is the fact that any important business in relation to the Thomson-Houston affairs will not from actual necessity be made known through any presumed or assumed news agency at Haverhill, Mass. In two particulars, at least, our readers may rest assured. First, that whatever the deal may be, the management of the Thomson-Houston Company do not deem it necessary to consult the general public or make of them confidants in any particular. Secondly, the management of the Lynn company will never enter into an agreement whereby the minority stockholders of Thomson-Houston will be deprived of any rights they now enjoy."

C. & C. FAN OUTFITS.

The C. & C. Electric Motor Co., 402–404 Greenwich street, have issued a neat little pamphlet on "Fan Outfits," a subject that becomes of special interest as the warm weather advances. These outfits have now been in the market for four years, with growing popularity; and the styles now illustrated are such as to meet the most varied wants. At the end of the pamphlet is given a list of some of the users of the apparatus. It is only a partial list, but gives a good idea of the range of work being done.

THE NATIONAL FEED WATER HEATER IN ELECTRIC LIGHTING AND POWER PLANTS.

The National Pipe Bending Company of New Haven, Conn., manufacturers of the National Feed Water Heater, report an active demand, having sold 35 heaters in February and 47 in March, including one 200 horse-power to Haddenfield Electric Light Company, New Jersey; one 300 horse-power to Consolidated Electric Light Company, Great Falls, N. H.; one 600 horse-power to Albany, N. Y.; one 200 horse-power to Westinghouse Electric Company, Bluff Point, N. Y.; one 150 horse-power to Citizens' Electric Light Company, Burlington, Vt.; one 200 horse-power for a Spanish Electric Company; one 200 horse-power to Newport, R. I.; one 150 horse-power to Spanish Electric Light Company, Puerto Principe, Cuba; one 100 horse-power Edison Electric Company, Martinsburgh, W. Va.; one 150 horse-power to Hyde Park Electric Company, Hyde Park, Mass.; one 150 horse-power to Electric Light Company, Jamaica, West Indies, and one 500 horse-power to Utica Electric Railway Company, Utica, N. Y.

KORTING GAS ENGINE CO.

The annual meeting of the stockholders of the Korting Gas Engine Co. was held on April 3, at the company's office, 74 Cortlandt street. The following officers were elected for the ensuing year: President, George W. Sillcox; Secretary, Maximilian E. Mora; Treasurer, Arthur Kitson; Assistant Treasurer, M. E. Mora. The business done during the past year was exceedingly satisfactory, and showed an increase of 100 per cent. over the amount done during the year preceding. Mr. A. Keating has things in charge at headquarters and reports that the company is full of orders and new business.

THE MAGNOLIA ANTI-FRICTION METAL COMPANY.

One of the most successful and pushing of the great soap manufacturers in England has made a great hit by his patronage of the fine arts, buying up and reproducing pictures and statuary that served in any way to illustrate the principle that cleanliness is next to godliness, and sometimes preferable. Our good friends, the Magnolia Anti-Friction Metal Company of 74 Cortlandt St., this city, bid fair to win like prominence in this country by their ingenious utilization of music and belles lettres. Their magnolia flower is familiar to everybody, but they recently "painted that lily" by bringing out the Magnolia waltz, with a beautiful title-page. This they have now in turn supplemented by a romance entitled "Luxilla," by George E. Miller, issued in neat brochure form with embossed cover. It can be had on application, or for 3 cents to cover postage. It is a fantastic prose poem, with not a few clever passages, suggesting now one of George Sand's best works, and again reminding the reader of Wilhelm Meister. We do not pretend to have the power to penetrate the mysteries hinted at, but there is some satisfaction in identifying such spiritual personages as Electro, Vapri, Dyni, and the like. The next thing we look for from the Magnolia Company is a thrilling melodrama, at Niblo's, where the plot turns on the ability of the Magnolia bearings in some huge marine engine to resist the evil work of a villain who seeks to drown in mid-Atlantic the heiress to untold wealth. We now file our application for a box.

NEW ENGLAND TRADE NOTES.

MR. DAVID CHALMERS, of the Empire City Electric Co., of New York, was in Boston, this week, looking up his many friends. The special purpose of his visit was to introduce in the east their new "Helmet Brand" insulated wires, which the Empire City company have recently commenced to manufacture.

MR. W. J. PILICY, has been appointed New England agent for the Card Electric Motor and Dynamo Co., of Cincinnati, O., and also for the Fidelity Carbon Manufacturing Co., of St. Louis. Mr. Pilicy has been connected with electric business for about 15 years, and is familiar with it in all its various phases.

THE GOULD PACKING CO., of Boston, are doing a large business supplying electric light and power companies with their patent packing for engines. The packing is made of rubber and canvas, thoroughly saturated in a special solution, and is cheap and clean to use, giving no trouble to the engineer. All engineers would do well to procure samples, to assure themselves of its good qualities.

THE WALWORTH MANUFACTURING COMPANY of Boston are in receipt of orders from the Union Depot Railway Company of St. Louis, for 21 heavy anchor poles, weighing about 1,350 pounds each, and about 100 ordinary poles.

MR. SAM. ELDER, well known in electrical circles in the East, is going to Pittsburgh in the interests of the Brush Electric Company and the Short Electric Railway Company. Mr. Elder will be associated in Pittsburgh with Mr. John E. Ridall, for years the manager of the Brush Electric Light Company, in Pittsburgh.

THE COMPLETE ELECTRIC CONSTRUCTION COMPANY.

The above company, Mr. Seely informs us, will remove on May 1, from its present quarters, to 24 Cortlandt street, in order to secure larger facilities for its business. It has been enjoying a run of large work, and has recently been furnishing the wiring of the new *World* building on Park Row.

WESTINGHOUSE CONTRACTS AND EXTENSIONS.

BROOKLINE, MASS., and Johnstown, N. Y., are both going in for long-distance electric lighting. The electric light companies at these respective places have just concluded contracts with the Westinghouse Electric Co. for special machinery for long-distance lighting. The Brookline plant is to have an apparatus of 900 lights capacity and Johnstown of 500 lights capacity.

THE OURAY, COL., ELECTRIC LIGHT CO., one of the oldest alternating current central station plants of electric lighting in the country, a few days ago contracted for an increase in its capacity. The Westinghouse Electric Co., is now occupied with putting up one of its 750 light machines, making the total capacity of the plant 1,500 lights.

FOR some months a 750 light alternate current incandescent machine of the Westinghouse manufacture has been in use at Sherman, Texas. The company operating the machine is evidently well pleased with its workings, for it has just placed with the Westinghouse company, an order for an additional machine of 750 lights capacity.

MOUNT MORRIS, N. Y., is not a very big town, but the people who dwell in it are to have the advantages of electric lighting. An order was recently placed with the Westinghouse Electric Co. for a 500 light outfit for Mt. Morris, and no time will be lost in the installation of the apparatus.

THE UNITED ELECTRIC LIGHT AND POWER CO., of Springfield, Mass., ordered a few days ago from the Westinghouse Electric Co., an increase of 3,000 incandescent lights capacity to its present plant. The United company has in use Westinghouse dynamos of a capacity of more than 5,000 lights, and with the addition of the late order will have a plant of very considerable size.

THE WESTINGHOUSE ELECTRIC CO. has just closed an order for a 750 light incandescent outfit to go to St. Thomas, Ont. The St. Thomas Gas Co. is the buyer. The plant is to be installed at once.

MARTIN'S FERRY, OHIO, is to use the new Westinghouse arc lighting system. An order has just been placed with the Westinghouse company for a 40 light machine.

THE UXBRIDGE & NORTHBRIDGE ELECTRIC CO., of Northbridge, Mass., which is using the Westinghouse incandescent system, has decided to embark in arc lighting, and with that end in view has placed an order for a Westinghouse arc light machine of 60 lights capacity to be shipped as soon as possible. Orders are coming in rapidly for the new arc lighting apparatus of the Westinghouse Electric Co., and satisfactory reports are received from those who have put the apparatus in use.

SUSQUEHANNA, N. Y., is soon to be a well lighted town. The residents of the place will have at their command the light supplied by the Westinghouse alternating current system, and the streets will be rendered safe by illumination derived from the arc lighting apparatus of the same make. The company which is to do the lighting starts out with a capacity of 750 lights incandescent and 80 lights arc.

THE WESTINGHOUSE arc lighting system has been adapted by the Evanston (Ill.) Electric Illuminating Co., which has for some time been employing the incandescent apparatus manufactured by the Westinghouse company. The arc light plant will have an initial capacity of 120 lights.

THE WESTINGHOUSE ELECTRIC CO. has an order from Joliet, Ill., for one of its new arc machines of 60 lights capacity. The order comes from the Joliet Electric Light Co. which is running an incandescent plant of the Westinghouse system.

.... THE dynamo-designer must get used to thinking of distances, not in inches, but in centimetres. There is no doubt that this is a great affliction, for he still uses the inch as his unit of measurement when making calculations of strength and stiffness. —*John Perry.*

.... DYNAMO building is now a small branch of mechanical engineering, but it is already infinitely further advanced than could have been expected in so short a time. A dynamo can be designed to give the desired output within one or two per cent.; yet though steam engines have been made commercially for about 10 times as long, no such results as this are possible with them.—*Industries.*

THE EDISON MACHINE WORKS.

The fourth annual banquet of the Edison Mutual Benefit Association was held at Schenectady on April 19, when some 350 men from the big machine works sat down together. The menu cards were finished in the form of an Edison dynamo, and with a tinted and bronzed fac-simile of a dynamo on the outer side. At the head table, in front of the stage, sat the officers and directors of the association, the invited guests, and the members of the orchestra. The officers, elected April 2, 1890, were: President, W. George Rothwell; vice-president, C. F. Hild; secretary, Ernest J. Bergren; treasurer, William Tanis. The directors, elected at the same time, were: Peter Weber, H. M. White, W. G. Shaible, H. Fitzgerald, Emil Kolben, C. Granneman, C. S. Moore, James Clark, Alfred Lundgren, M. Swart, John Waldron and C. Pink. The association is doing a good work.

WESTERN TRADE NOTES.

SHAY, STEPHENS & CO. are doing their usual large amount of business in their electrical glass specialities, notwithstanding that their prices on battery jars have been recently advanced somewhat, due to scarcity of material employed. The special glass insulator for inside work which this company manufacture largely is meeting with great success. It is claimed to be preferable to the ordinary porcelain insulators on account of its higher insulation and increased durability.

THE SPRAGUE ELECTRIC EQUIPMENT CO. have just closed a contract to build the new electric road at Elgin. This road will comprise 10 miles of track and operate 9 motor cars and quite a number of trailers. The Elgin company have recently purchased an Edison light plant, and propose to run the two businesses in co-operation. The Sprague company has recently started electric cars in Milwaukee on the Wells street line and also on the Twelfth street line, and within a few days will be running over the Grand avenue line. A very handsome marble switch-board has been installed in the station on which the various switches and measuring instruments are located.

MR. FOREE BAIN, who was selected as Consulting Electrical Engineer by the Minneapolis Street Railway Co., has just returned from a short trip to that city, where he went to confer about the new electric system.

THE ELECTRICAL SUPPLY CO. have recently received some very large consignments of the well-known Habirshaw rubber wires, and will carry a complete and extensive stock right along, enabling them to fill orders, no matter what their size, at very quick notice. Notwithstanding that they have but recently taken hold of these wires in the West, they have already closed some large contracts, and are beginning to receive numerous small orders from all parts of the country.

THE WESTERN ELECTRIC CO., have now completed the additional two stories which they have added to their enormous factory on Clinton street. They employ in the neighborhood of 1,100 hands right along, and the quantity of supplies of all kinds and specialties which they turn out daily is stupendous. Now that their building is completed, they propose to increase their magneto-bell, switch-board, wood-working and insulating departments, for which purpose their extra space will be employed. It is needless to say that they are busy all the time. Their Patterson cables are meeting with great success for underground work, carrying currents of very high tension successfully. The Chicago Arc Light and Power Co. are using large quantities of this cable for their underground circuits and continually making additions to the already large amount which they are employing.

THE STANDARD UNDERGROUND CABLE CO. have recently shipped 10 miles of their standard weatherproof wire to Utah, and are busily employed trying to catch up with their orders, which keep coming in all the time. They are going to put up new works to cover an area of four acres, situated at Wilmerding, in the vicinity of Pittsburgh, which will be pushed through without delay, thereby giving them greatly increased facilities to meet their rapidly growing trade. Amongst other orders they have just shipped 20,000 feet of telephone cable to Minneapolis.

MR. GEORGE CUTTER, 80 Adams street, Chicago, has returned from his trip East in first-rate health and spirits. While away he became interested in a new anti-induction telephone wire, by the employment of which the instrument is totally unaffected by any outside currents and altogether independent of single wire trolley or alternating systems. Circuits will be put up right away in the West under the most severe conditions that can possibly be brought to bear upon the test, and some interesting developments will no doubt be forthcoming. Mr. Cutter has also, it is said, purchased a large interest in the Simplex Electrical Co. He has also taken hold of a new electric water purifier, of which great things are expected, and for which certainly the field is large enough, so that, all told, Mr. Cutter seems to be one of the most hopeful men I have met for quite a while.

AN ENORMOUS ORDER FOR ROEBLING ELECTRIC WIRE AND CABLE.

With regard to the large order recently given to John A. Roebling's Sons Co. by the Minneapolis and St. Paul electric roads, Mr. George C. Bailey, the manager of the Chicago house, writes us that the original contract was for about 100 miles of lead encased cable and 100 miles of overhead conductor, as well as a large amount of bare copper wire and connectors, etc. This is said to be the largest contract that has ever been taken in this country or Europe for this line of goods. The deliveries are to begin early in May, and all is to be delivered by July 1. The order was placed through the Chicago branch of the concern.

PERKINS LAMP COMPANY.

The annual meeting of the Perkins Electric Lamp Company was held at the company's office on Pearl street, Hartford, last week. Every one of the thousand shares was represented. A dividend of ten per cent. was declared. It was voted to move the main office to Manchester as soon as suitable quarters could be obtained. The old board of directors was re-elected as follows: M. S. Chapman, J. J. Gates, W. G. Halm, W. B. Whiting and C. T. Welles. The directors re-elected the old board of officers, viz.: President, M. S. Chapman; vice-president, W. G. Halm; secretary, J. J. Gates; treasurer, C. T. Welles. It is said that the capacity will be doubled.

NEW ENGLAND TRADE NOTES.

Another Wire Factory.—It is reported that a lot has been purchased and another insulated wire factory, 45x90, one story high, to be run by electric power, is to be immediately put up on Water street, Plymouth, Mass.

Mr. W. E. Stowe is at present busy installing a Thomson-Houston isolated plant in the store of Messrs. C. F. Hovey & Co., and his friends are all congratulating him upon his ability to resume active work, after his long sickness. The plant consists of a 30-light arc dynamo, and a 200 incandescent dynamo, to be driven by a 45 h. p. McIntosh & Seymour engine.

The Robinson Radial Car Company will have running within the next few days on the tracks of the West End Company in Boston, their new large closed car, which will have a seating capacity for forty people. They are also busy preparing for the same company fourteen trucks for open summer cars, which will each have a seating capacity of 50.

The Brown Electric Protector Company are about to be organized, with headquarters at 54 Devonshire street, for the purpose of pushing the sale of the Brown electric protector, a well known successful device for protecting delicate instruments, such as telephones, time clocks, fire alarm apparatus, etc., from heavy currents, should the wires become crossed. Several prominent electrical and insurance men are interested in the company, who will lend their valuable influence in pushing the instrument, which has already had a very successful career of about 2½ years.

Mr. Paul D. Chase has just been appointed New England agent for the Daft Electric Light Co. of New York, and will hereafter push the Daft system of electric railway in New England. The Daft Co. have a double trolley track in operation in Meriden, Conn., and have just made a contract in Gloucester, Mass., for a double trolley system, consisting of five miles of track and three cars at present. All the details of the system are now perfected, and Mr. Chase claims that they have effectually got over all the trouble of frogs and switches which might be expected from a double trolley system. Mr. Child, of the Daft Co., has gone to Gloucester to arrange details and lay out the pole line.

The Wright Electrical Engineering Co. recently completed the rewiring of the well-known steam yacht "Sagamore," the property of Mr. W. A. Slater, of Norwich, Conn. A new set of accumulators, 54 in all, were put in, with water-tight and acid-tight hard rubber cells, giving a potential of 110 volts, and yielding current enough for 100 16 c. p. lamps. Porcelain switches, and slate and porcelain cut-outs have been used throughout. The switch-board was made by a ship carpenter, and is of black walnut. The dynamo, of the Edison type, and accumulators, are run at the same time, and the accumulators are run alone in the evening when the steam engine is stopped. Automatic charging cut-outs have been used, so as to prevent the batteries from charging back into the dynamo. Edison fittings are used, and the general appearance is very handsome. The accumulators were specially made by the Accumulator company, of New York, so that they could be tipped to an angle of 30 degrees without spilling. A complete set of Weston ammeters and voltmeters has been fitted, and everything done to make the plant thoroughly reliable and efficient.

Mr. H. E. Duncan, of the American Waltham Watch Co., who has recently returned from an extensive and successful business trip on the Pacific slope, entertained a few gentlemen this week, interested in electrical affairs, by conducting them through the mazes of the Waltham Watch Co.'s factory at Waltham, Mass. The party consisted of Mr. A. B. Griggs, a gentleman well known in electrical circles, but more recently known as the promoter of the "Teleport," Mr. Stanton Day, Mr. W. E. Stowe and the writer. Commencing with the machine shop in which about $2,000 is spent every week in perfecting machinery for the manufacture of the watches, Mr. Duncan took the party over the whole establishment, winding up with a visit to the *sanctum sanctorum* where the most delicate adjustment of the high grade instruments is made. To attempt a description of the factory in these brief notes would be entirely futile, but it may be said that the machines for the manufacture of the 460 various parts of which a watch is composed, are simply wonders of accuracy, and being chiefly automatic are a source of intense interest, as showing the perfection of mechanical art. The factory at present is extremely busy, some 2,700 employees being engaged in producing about 1,700 watches every day, and more space is now being added. Mr. Duncan was sincerely thanked for providing a most enjoyable and interesting afternoon.

WESTERN TRADE NOTES.

Mr. E. D. Floyd, so well-known in the west as purchasing agent of the Thomson-Houston Co. has resigned his position here and goes to Boston to fill a similar position with the parent company there.

Mr. G. A. Kohler, agent for the Eddy Electric Mfg. Co., of Manchester, Conn., has opened an office in the Rookery, where he will carry on business selling this well-known motor, which has met with a wide adoption and use by reason of its many excellent qualities. Mr. M. E. Baird, of the Eddy Co., was in town this week.

Wm. Baragwanath & Sons are very busy manufacturing their feed water heaters, and have recently received quite a number of fine orders, one 2,000 h. p., one 600 h. p., one 400 h. p., one 1,000 h. p., and two 800 h. p., are among the list. These heaters have given great satisfaction wherever used, and their numbers are rapidly increasing.

The Rice & Whitacre Mfg. Co. are doing a large business in their Stationary Marine & Hoisting Engines. They have two engines of 90 h. p. each, furnishing power for the electric lights in the Terminal station of the West side cable plant. They make a speciality of small engines, boilers, and electric launch work, and their "Kriebel" engines are receiving much commendation for their general merits and efficiency.

The Central Electric Co.—Among their numerous recent orders may be noted the sale of a 14 conductor Okonite telephone cable for aerial work. They report that the demand for high class testing instruments is increasing very rapidly, and that their Weston voltmeters and ammeters are in large demand. These instruments have acquired a reputation throughout the country for their extreme sensitiveness and accuracy, while at the same time embracing numerous features of convenience and durability which have too often been lacking in instruments of great delicacy. The location of the company on Franklin St. is becoming quite an electrical centre. The Central Union Telephone Co. have recently moved in right back of their building, and already in the near vicinity are situated the Chicago Telephone Co., the Chicago Arc Light and Power Co., and Foree Bain.

Mr. Gilbert Wilkes has resigned from the Navy and joined the United Edison Manufacturing Co. at 65 Fifth avenue, New York.

The Edison General and Sprague Co.s are now being represented in Chicago by Mr. S. Dana Greene and Mr. C. A. Benton, both of whom have gone on recently to take charge of affairs there.

Knight Bros., the well known patent solicitors and experts, will remove on May 1 from 234 Broadway to Temple Court, 121 Nassau street. The firm is composed of O. Knight, H. Knight, and H. E. Knight.

The Fort Wayne Electric Co. have bought the Waterhouse Company, of Baltimore, and have secured an option on the International Co. of the same city, which is operating incandescent lights on the Heisler system. Options on several other electrical enterprises in Baltimore have been secured by the Fort Wayne company.

Pan-Electric.—A special dispatch from Washington of April 21 says: "In the court in General Term to-day, a decision was announced in the celebrated Pan-Electric case, otherwise the case of J. Harris Rogers against ex-Attorney General Garland, General Joseph E. Johnston, Isham G. Harris, John D. C. Atkins, and Casey Young. Judge Cox delivered the opinion of the Court. The case has been in the courts since the Summer of 1886, and was brought for dissolution of partnership, an accounting, etc. The bill is dismissed, each party to pay his own costs."

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. IX. NEW YORK, MAY 7, 1890. No. 105

No one can do harm but only good, who works with an earnest and truthful spirit.—Faraday.

MUNICIPAL AGGRESSION UPON PRIVATE PROPERTY.

THE recent decision by the Supreme Court of Ohio, in the case of the State *ex rel.* Hamilton Gas and Coke Co. *vs.* City of Hamilton, of which some account is given in the legal department of our present issue, affords an instance of the apparently growing tendency of courts in this country to decide adversely to the interests of private property where conflict with municipal, state or national interests appears to arise. In this case no electric interests are directly involved; but the result may have a very important influence upon the welfare of electric lighting companies which may similarly find themselves face to face with threatened confiscation of their property.

The Hamilton Gas and Coke Company had invested in gas works, and supplied the city and its citizens with light since 1855, under the general incorporation act of 1852, and under a municipal franchise of the city of Hamilton, when in 1888, the city, by ordinance, ratified by a vote of its electors, went into the gas lighting business. The municipal works, since their completion in 1889, have furnished the city lighting, and may at any time undertake private lighting; thus seriously impairing and threatening to destroy the value of the Gas and Coke Company's property. The suit instituted by the company for the protection of its property and business has been determined against it by the court, which rules virtually that a gas company, established and conducted under a municipal franchise, can maintain no legal protection against competition by the municipality which has granted its franchise, even when such competition may practically confiscate the property of the company.

We commend to our readers a perusal of the extenive extracts from the energetic dissenting opinion by Judge Spear, printed in our legal columns.

The convenience and rights of the municipality and of the citizens, as against the gas company, were duly protected by provisions in the general law and its amendments, obliging the company to furnish all required service and to submit to municipal regulation of prices. There was no allegation that the company had failed in any lawful requirement. Judge Spear says:

> Under this law, so long as a company complied with every lawful requirement to the public and to private consumers, the public object of the statute was accomplished, and, if the construction I contend for be correct, the right of the company to furnish gas to the city and to private consumers therein remained unimpaired, and the city had no power to interfere with the company's chartered rights by entering into competition with the company while carrying out the purpose of its organization. It is not pretended that this company has, in any respect, failed in tne performance of any lawful requirement.
>
> * * * * * * * * *
>
> In effect the statute gave to this company the exclusive right, so long as it complied with every requirement of law, to supply gas to the city of Hamilton and its inhabitants.
>
> * * * * * * * * *
>
> The construction of the statute claimed by the city is not reasonable. It shocks the moral sense. * * * *
>
> In this case the state held out the inducement to all citizens to organize for the purpose of supplying a public want of municipal communities. The incorporators of the Hamilton Gas Light Co. accepted the state's proposition as regards the city of Hamilton. No other citizens did accept it. The company then went forward, and, in all respects, performed the duty, complied with the law as it then was, and with all amendments as to its proper regulation which have since been enacted. With what grace can the state now say to it, "You must withdraw, and leave to another agency the performance of the duty we intrusted to you, and lose the value of the property you have acquired in performing that duty, —property which, from its nature, can neither be removed nor profitably applied to any other purpose?"

This case illustrates the unsatisfactory situation of gas and electric lighting companies, depending as they do upon "the caprice of city councils or the impulsive vote of the people." There results from this state of affairs hesitation of capital to undertake enterprises of this kind; necessity of large earnings to compensate for risks; unequal prices in different cities, and consequent dissatisfaction and distrust on the part of the public; attempts on the part of lighting companies to make their position more secure, which elicit opposition from the public and accusations of unfair dealing, and generally a state of warfare between these public service companies and the communities in which they operate.

It is not necessary to point out the advantages to all concerned—and everyone is concerned—in a different state of affairs; in having investments in this class of enterprises made secure, and thus enabling capital to be obtained readily for reasonable returns; in having prices differ only as recognized controlling conditions differ; and in removing the asperity and friction between the public and the companies which serve them.

It would seem that a feasible plan for accomplishing this is to secure the appointment of a commission in each state, similar to the one now giving satisfactory results in Massachusetts, with authority to prevent competition either on the part of municipalities or on the part of other private corporations, and at the same time giving the public protection by regulating prices.

AMERICAN ELECTRICAL UNITS.

THE additions made to electrical nomenclature by the naming of various units have been the necessary outcome of the desire to avoid periphrasis and to fix the units as a permanent part of the science. It was but proper that in the selection of their names the illustrious men to whom the science of electricity is so much indebted should be commemorated, and no more fitting monument could be devised to that end. Up to the present time such units have been derived exclusively from the names of European scientists, and hence not without cause there has arisen on this side a desire to have some of our own illustrious men of science recognized in a similar manner. The American Metrological Society has inaugurated a movement with this object in view, and will, we are sure, receive the hearty co-operation of all the societies as well as the individuals interested in electrical matters. As Mr. F. B. Crocker points out on another page, the names of Franklin and Henry are eminently adapted for the naming of units now constantly employed and which are of increasing importance. Though probably subject to the action of an Electrical Congress for final acceptance, these terms might be embodied at once as part of electrical nomenclature so as to make their use familiar as soon as possible. Such was the course pursued in relation to the term "watt," which was in current use several years before being officially adopted as the unit of electrical power. We shall lend our aid to any movement looking to the proper recognition of eminent American electricians, and trust that the prominent electrical bodies will take up the subject in earnest. It deserves mention in passing, that the suggestion of the "henry" came from Dr. Pupin, of the Columbia College Electrical Department.

UTILIZING NIAGARA.

Now that the plan of utilizing the the water power of the Niagara Falls is to be put into practical execution, in a local distribution of power to begin with, it will not be long before the electrical engineer will be called upon to transmit a considerable portion of it to districts several miles away. The all-important question, after the kind of current to be employed—whether continuous or alternating—is settled, is, of course, the potential to be adopted, which involves the size of the conductors. It is fair to assume that under whatever system of transmission adopted, whether alternating or continuous, series or parallel circuit, a reduction of pressure from the main to the distributing lines will have to be effected, so that the question of insulation of the main line alone will need serious consideration. One of the plans already suggested is to lay a cable from the Falls to Buffalo on the bottom of the Niagara River. While such a plan is undoubtedly feasible, it seems proper to inquire if the ordinary overhead air-insulated conductor would not fulfill all the conditions of safety and economy and present other advantages over the submerged or buried conductor. With proper construction and inspection and the application of well-known devices, a bare copper wire suspended overhead could be made reasonably safe even with a very high potential and, its dangerous character being known, it would be avoided, as much as the railroad track is, as a promenade. The cheapness of the insulation will be a large factor in determining the position of the line. With the high potential to be employed, any insulating material other than air, and the protecting armor, would probably cost as much as, if not more than, the copper itself and would thus figure as a large item of the cost. As Sir Wm. Thomson recently pointed out there can be not the slightest objection raised to the adoption of bare wires carrying high potentials, outside of populated district,s and the many advantages of this method of construction are too apparent to require pointing out. Long distance power transmission in such districts will, we believe, be largely done with bare conductors, and, in our opinion, with perfect propriety.

Air in Incandescent Lamps.

THE substitution of the carbon filament for the metallic made the employment of a vacuum within the enclosing globe a necessity in order to prevent the combustion of the filament. But another and important function of the vacuum, which is often lost sight of, is its effect on the efficiency or power consumed by the lamp for a given illumination. This is forcibly pointed out in the short paper appearing in another column which shows that two lamps with identical filaments, but unequally exhausted of air, may differ several hundred per cent. in efficiency. These experiments may also serve as reminders and warnings to those who, from time to time, propose the substitution of some inert gas for the vacuum in incandescent lamps, unmindful of the fact that the vacuum plays a double role.

Specific Resistance of Metals.

IN this issue we bring to a close a very interesting and exhaustive essay by Mr. Geo. B. Prescott, Jr., on a subject of considerable importance. Nearly all electrical calculations involve the resistance of metals, and the conflicting conditions of "standard" tables have long been a subject of comment and complaint. That the experiments of Matthiessen upon which such tables are generally based, need revision is apparent when modern methods of manufacture can produce specimens of copper, for instance, showing several per cent. increase of conductivity over that obtained and adopted, by Matthiessen. Again, the discrepancies to be found in tables derived apparently from the same authorities have also given rise to confusion, and Mr. Prescott shows in what manner the divergences can be accounted for. As suggested by Mr. Prescott, who has long made the matter a special study, the time has certainly arrived when a revision of this important standard should be undertaken with the refined materials and apparatus which are now at our command.

Julien Storage Battery Interests.

WE are informed, upon the authority of the president of the Julien Electric Company, that we were premature in including the Julien interests among those consolidated in the newly organized United Electric Traction Co. noticed in our editorial columns last week. Mr. Bracken informs us that his companies have not been absorbed in the United Electric Traction Company, whatever current reports there may be to the contrary.

AMERICAN ELECTRICAL UNITS.

BY FRANCIS B. CROCKER.

THE suggestion has often been made that one of the practical electrical units, which it has been the custom to name after some eminent electrical scientist, should be given an American name, but as yet none but foreign names have been adopted. If the opportunity passes and no American monument is erected in the electrical Temple of Fame, it will be a reproach to the patriotism of our electrical engineers; it will be a very undeserved slight to the great contributions to electrical science made by Americans, and will not truly represent the greatly advanced state of electrical science and industry in this country.

To accomplish anything in this direction requires positive and concerted action on the part of the various societies interested in the matter. With this object in view I attended recently, as the authorized representative of the American Institute of Electrical Engineers, the meeting of the American Metrological Society, held at Washington, April 21, 1890. This latter society interests itself with units and standards generally, and has done some very excellent work during the last ten years in connection with the introduction of standard time, the metric system, etc.

At this meeting the following resolutions, introduced by Dr. T. C. Mendenhall, were unanimously passed:

> *Whereas*, It has been generally admitted among scientific men that the nomenclature of electrical units of measure should perpetuate the names of early electricians who have contributed most to the advance of electrical science; and
>
> *Whereas*, In the names thus far adopted, the eminent services of Americans have not been recognized; therefore,
>
> *Resolved*, That, in the opinion of the American Metrological Society, a just distribution of the honor thus bestowed, demands a recognition of the splendid contributions of one or both of America's great electricians, Benjamin Franklin and Joséph Henry, and that the society will gladly co-operate with the numerous organizations of electricians in the country, in an earnest effort to secure such action.

The question as to what particular unit should be selected was not specially considered at this meeting, as it was thought that this matter should properly be left to the electrical societies to decide.

In this connection I would like to call attention to the peculiar fitness of the name of Henry, for the unit of self induction, which name has been suggested to me by Dr. Michael Pupin. It was he who discovered self induction in 1832. Yet in spite of this fact the last Paris Electrical Congress (1889) ignored Henry's actual right to have the unit given his name, and American claims in general, and called the practical unit of the coefficient of induction, the "quadrant."

But this name is not at all satisfactory since it already has another significance which completely overshadows the electrical meaning. It is well enough to use this as the *value* of the practical unit, and say that it is numerically equal to the earth's quadrant expressed in centimetres ($1,000,000,000 = 10^9$); but it needs a *name* besides, and since Henry was the first and greatest investigator of self induction phenomena, nothing could be more appropriate than to give it his name.

The only objection to this is that the name of Franklin should naturally take precedence; but this can be overcome by naming another unit after him. The unit of specific inductive capacity, for example. It would be an improvement on the present clumsy expression, and although Franklin knew nothing of inductive capacity, he knew fully as much as Watt knew of watts, or Volta of volts. Moreover, he was the true founder of the modern theory of electricity developed by Faraday, Maxwell, Hertz and others, in which the dielectric plays such an important part.

There are other electrical units to which names will probably be given before long, for example, a unit of intensity of magnetic field which might be 1,000 or 10,000 c. g. s. lines of force per square centimetre, a unit of magnetic permeability or conductivity, and, perhaps several others.

It may be said by some that we do not want any more units, and, therefore, no names are needed for them; the fact is, however, that one or more electrical units are sure to be named and used in the near future, and, moreover, the necessities of more extensive electrical work demand them. When we have to use the expression "an intensity of magnetic field of 10,000 lines of force per square centimetre" very often, we will be very glad to substitute an expression like "one Franklin."

The best way to actually accomplish the fixing of an American name upon some electrical unit would seem to be for the American Institute of Electrical Engineers to take suitable action at the coming annual meeting in Boston this month, and the co-operation of local electrical societies, as well as of influential individuals, should also be secured. If in this way the movement is well started before the next Electrical Congress, the name, or names, will probably be adopted. There is another matter coming directly under the title of this article which needs and deserves attention from American electrical engineers. It is the fact that the United States Government should possess a collection of the electrical standards of the highest attainable accuracy, with means for comparison and verification, and these should be deposited at Washington in charge of a competent officer. Fortunately, the Superintendent of the Coast Survey, Dr. Mendenhall, who is by custom and appointment the custodian of all the United States Standards of weight and measure (yard, pound, metre, kilogram, etc.,) is very much in favor of the plan, and since he has great familiarity with, and takes great interest in, electrical matters, he is eminently well qualified to have charge of the electrical standards also.

Apparently the only way to carry out this idea, is to present to Congress a petition signed by the officers of the principal electrical societies and companies, asking that, say $10,000 be appropriated for this purpose. It would not be a large sum for the government to expend for the advancement of electrical science in this country, considering the vast importance of electrical work in every State in the Union.

If this appropriation were passed it would make it possible for anyone to send standards to Washington for official verification in the same way that weights and measures are now verified for a merely nominal charge.

The possession of the electrical standards by the government would pave the way and probably bring about the legalization of the electrical units by Congress, which is the last of the three important American electrical unit matters which now present themselves to the electrical engineers of this country for their attention and action.

ON A NEW SYSTEM OF ACCUMULATORS.

BY CHARLES POLLAK.

IN my researches on the accumulators of the Planté type it has been my aim to give them a large storage capacity in as short a time as possible. To that end I cover the plates with spongy lead obtained by the electrolytic method. In order to obtain the perfect adherence between the spongy lead and the surface of the plate, the latter is worked in such a manner as to present the appearance of a short hair brush which is obtained by means of a special laminator. These points are 2 mm. high and 1 mm. at their base. The interstices between the points are 1 mm. across. The plate after having been washed in order to remove the fatty matter, is covered with a paste composed of sulphate of lead mixed with salt water and immersed in salt water between two plates of zinc. The reduced plates present a uniform, gray appearance. The adherence is perfect between the spongy lead, the surface of the plates and the points.

After having soldered them the formation of the accumulator is proceeded with, which is effected by passing the current in the same direction for 50 hours. The negative plates have a grayish aspect; the positives are a dark brown. After the formation, the adherence of the active matter (spongy lead and bi-oxide of lead) is so great that one is unable to distinguish the boundary between the plate and the superposed layer. An accumulator composed of nine plates of which four are positive and five negative, and having a total weight with the connecting strips of 11.2 kilograms, after 45 hours formation with a current of 16 amperes gave the following current during discharge :—

Hours.	Amperes.	Volts.
12 M.	18	2.12
1	“	2.08
2	“	2.
3	“	2.
4	“	2.
5	“	1.9
5.18	“	1.8

Total, 95.4 ampere-hours of useful work.

The resistances through which the discharge took place were so regulated that the current strength remained the same throughout. The same accumulator, re-charged with a current of 16 amperes for 7 hours, gave the following on discharge :—

Hours.	Amperes.	Volts.
12 M.	17	2.2
1	17	2.
2	17	2.
3	17	2.
4	17	2.
5	17	1.95
5.30	16.5	1.92
5.45	16.4	1.87
6.40	16	1.8

The efficiency was therefore 91.384 per cent.; the capacity is 9.133 ampere-hours per kilogram of lead. It will be further seen from these two tables that the E. M. F. of the accumulators varies very little during the discharge but declines sharply toward the end.

The object has been to obtain in a small volume and with light weight a current of high E. M. F. which should be able to serve the particular requirements of a portable electric light. There has been constructed to that end a small battery of accumulators which I call a multiple accumulator. This is composed of plates of which each is positive on one side and negative on the other. The plates are bordered by rubber bands and separated by ebonite plates. The whole is perfectly water-tight.

THE EFFECT OF THE ELECTRIC CURRENT UPON FRICTION BETWEEN METALLIC SURFACES.[1]

BY LUCIEN I. BLAKE, PROF. OF PHYSICS, STATE UNIVERSITY OF KANSAS.

THERE has appeared from time to time in technical magazines and in newspapers the statement that an electric current passing through the surfaces of contact of a wheel and a rail upon which it ran, would decrease the tractive power by increasing the friction between the wheel and the rail. It has even been stated that 30 per cent. increase of traction could thus be produced with a current of 30 amperes. The importance of this fact to electric railways is evident.

With a view of determining the general relations between the strength of a current and the co-efficient of friction between metallic surfaces, a series of experiments was begun in September, 1889, in the physical laboratory of the State University. These experiments were carefully carried out by Mr. E. W. Caldwell, student in the electrical engineering course. The somewhat vague statements of the magazines were taken as authority for the fact of increased traction by the electric current.

The following four independent methods of experiment were devised :—

1. A column of mercury was made to flow between two platinum surfaces, each one inch square, each nearly parallel to the line of flow, and so arranged that a current could be sent, at will, from one platinum surface through the flowing mercury column to the other platinum surface. The accompanying illustration, Fig. 1, shows the general arrangement of the experiments, in which A and B are the platinum plates.

The time of flow of a given amount of mercury, with, and without, current, would serve as a method of determining the effect of the current upon the coefficient of friction of mercury and platinum.

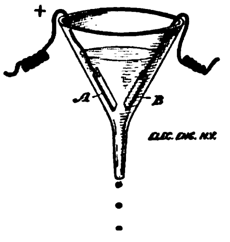

FIG. 1.

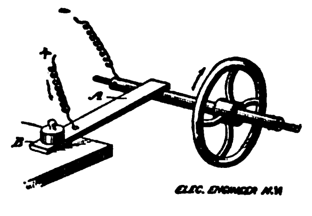

FIG. 2.

Two pounds of mercury were allowed to flow, and the time of flow without current was 29 seconds. A current of three volts, and varying from 0 to 1 ampere, was then sent from plate A to plate B through the mercury between them. No difference in time of flow was indicated. Mercury was selected, as no electrolytic action could take place at the surfaces of the platinum electrodes.

2. In the second method there was employed a steel spindle half inch in diameter, with a small fly-wheel 2½ inches in diameter rigidly attached to it. The arrangement is shown in Fig. 2. A small steel bar, four inches long, rested near one end upon the spindle at A. The other end rested upon a smooth stationary surface. The spindle was made to revolve at a uniform rate of speed. The friction between spindle and bar tended to roll the bar over the spindle; but by applying suitable small weights upon the bar at the end B, resting upon the smooth surface, the sliding friction at B was made to delicately balance the friction between bar and spindle at A, and the bar remained at rest upon the revolving spindle. A current of electricity was now sent through the contact of bar and spindle at A. No change in friction between bar and spindle could be detected.

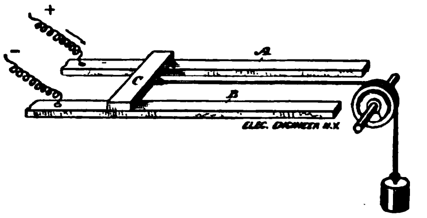

FIG. 3.

3. A third method was as follows: A metal bristle was soldered to the centre of the diaphragm of a Bell telephone, and projected a couple of inches out from its centre. The telephone was then so placed that the bristle rested across a rapidly revolving spindle, half inch in diameter. The friction of the bristle upon the spindle produced in the telephone a musical sound of definite pitch. A current of electricity was now sent through the contact between bristle and spindle. Had the friction been altered in any way the tone in the telephone would have been affected No change in tone was produced.

4. Finally, for a fourth method, an experiment with sliding friction was tried. Two highly polished brass ways, A and B, Fig. 3, about four feet long, were placed horizontal and parallel about three inches apart. A cross-piece of

---

[1] Paper read before the Kansas Academy of Science, Wichita, Kans.

brass, c, rested with its ends upon the strips. A cord attached to the centre of the cross-strip passed over a pulley and had suitable weights attached, just sufficient to so slightly overcome the friction of the strip upon the bars as to produce and maintain uniform motion of the strip to the ends of the bars. The surface of contact between strip and bars was made to vary in repetitions of the experiments from 1½ to 3 square inches. A dynamo current of 10 amperes was now sent through the surfaces of contact by connecting one end of each bar to one dynamo terminal. The friction was unchanged. Uniform motion was still maintained without altering the weights.

It should be noticed that the currents employed were not sufficient to produce heating at the surfaces of contact. Such heating would doubtless produce an increase of the coefficient of friction.

The four wholly independent methods described above would seem to justify the conclusion that the friction of rolling or sliding contacts is not affected by the electric current passing through the surfaces of contact, provided the currents are not strong enough to produce sensible heating effects.

Whether such heating effects occur between wheel and rail in electric railways, when transit is rapid, may well be called in question.

THE WIRT LIGHTNING ARRESTER.

During the time that the telegraph constituted practically the only industry requiring the transmission of current over conductors exposed to the effect of lightning discharges, a comparatively simple device was adequate to protect the instruments from destruction. With the introduction of electric lighting circuits carrying comparatively heavy currents under high pressure, it was soon found that the old and simple forms did not answer the requirements, as the currents from the generating machine followed the stroke of lightning and maintained an arc at the arrester, thus endangering the machine and other apparatus, while at the same time causing the destruction of the arrester.

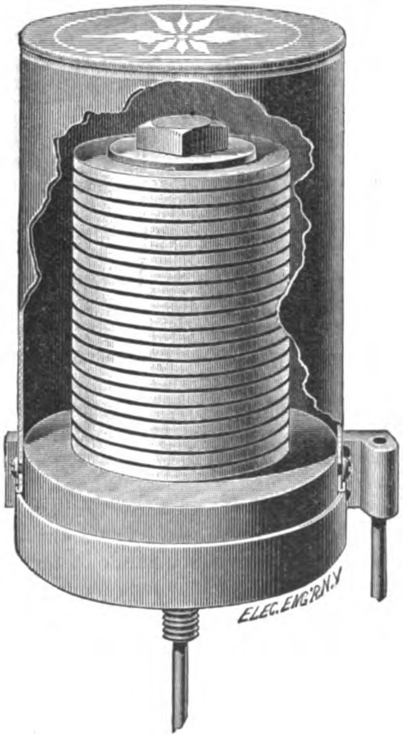

Fig. 1.—The Wirt Lightning Arrester.

Devices to overcome this difficulty were therefore invented, and have come into considerable use, and we desire to draw the attention of our readers to the latest of these, the invention of Mr. C. Wirt, which claims our attention on account of its originality and simplicity.

The object had in mind by the inventor was to provide an effective lightning arrester which should not have a single moving part, but which should prevent the maintenance of an arc by the cooling effect of a large mass of metal with numerous small breaks.

This has been accomplished by the construction illustrated in the accompanying engraving, Fig. 1, which shows the arrester in perspective in half its true size, with the cover broken away, so as to expose the interior. The section of the apparatus, illustrated in Fig. 2, gives a clear view of its parts. As will be seen, it consists of a series of metallic discs A insulated by mica washers B, all of which are mounted on a central bolt C. The bolt, besides holding the discs together, connects the top disc to the line through the leading wire attached to the screw end. The insulating tube D and the insulator E serve to separate the line connection from the ground-wire, which is attached to the base F.

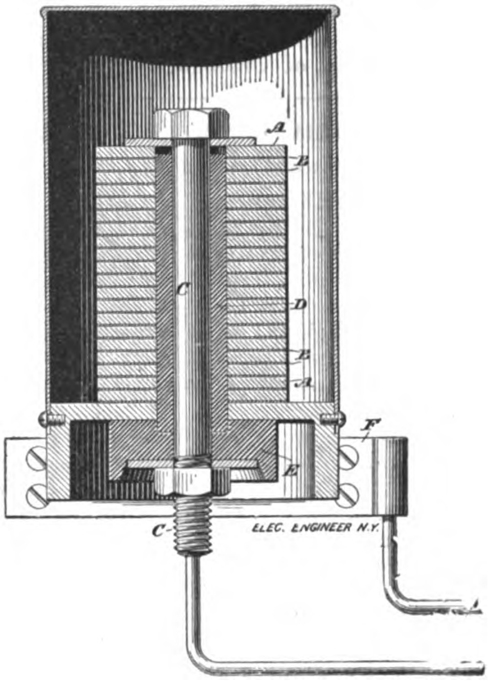

Fig. 2.—The Wirt Lightning Arrester.

It will be seen that by properly covering the terminal end of the bolt C, there will be no conducting parts exposed. In some situations this is an important feature of safety. The breaks between the discs are only about .002 inch in width; thus the aggregate distance to be bridged by the lightning spark is less than the single break generally in vogue.

The principle is a very beautiful one, and its effectiveness is best shown by starting an arc from a high tension dynamo over the surface of the arrester in any convenient manner. This cannot be done in the ordinary way with an induction spark, but actual experiments have shown that a current which will maintain an arc four inches long in the air will not hold an instant when divided by the breaks of the arrester, although the aggregate length of all the breaks will not exceed 1-20 of an inch.

The arrester illustrated is designed for indoor or outdoor use on all classes of circuits, and wherever protection is called for. As it needs no fuse, no inspection, and is weatherproof, it is especially suited for use outdoors. The difficulty of getting good service out of an arrester on poles, has led to dependence being placed on arresters placed in the station. There is no doubt that lightning should be kept as far as possible away from dynamos, no matter how well they may be supplied with protecting devices, and the arrester just described can be employed in the situation mentioned. Its construction also adapts it for use on electric cars, the motors of which are especially liable to destructive lightning charges. It will be noted that the construction adopted also obviates all electro-magnetic coils or solenoids which might offer a resistance to the discharge on account of their self-inductive action. It is claimed that while affording the readiest possible path to earth for all static charges, it is impossible for the dynamo current to pass when the arrester is properly designed for the tension of the circuit it is to be used with. The manufacture of the Wirt arrester has been undertaken by the Electrical Supply Co., of Chicago.

ANOTHER CRITICISM OF "MUNICIPAL LIGHTING."

BY HUNTINGTON LEE.

In The Electrical Engineer of April 9, on page 215, there appears an article by Mr. Rosewater on the cost of electric lighting, purporting to show that it is much cheaper for municipalities to operate their own electric light plants than to contract for them from a corporation. In the following issue on page 234 there appears a well-put protest by Mr. M. J. Francisco. I think that possibly a few more facts will be of interest, however, so I intrude this on your space.

Particular stress seems to be laid on the fact that Ypsilanti, Mich., is able to run its own plant every night at a rate of $23.61. A quotation from Mr. Fred. H. Whipple's able book on "Municipal Lighting," bearing the date of 1889 (which has an enviable reputation for accuracy) rather differs from this. He says: "In 1887 Ypsilanti, Mich., purchased an Indianapolis Jenney plant of 60 arc lights, paying $10,800. This did not include building, setting machinery, etc.; since then 20 lights have been added and, other changes made, bringing the cost up to $26,000. The lights burn an average of 18 nights a month till midnight, and with an independent steam station cost $40 per light; with added interest, etc., the cost is $72." I notice a few more errors in Mr. Rosewater's figures in regard to cities operating their own plants. Below I give you a correct table showing the lights and cost, in these cities:

Aurora, Ill............	80 lights..........	$95 per year.
Bay City, Mich........	182 "	82 "
Dunkirk, N. Y.........	56 "	62 "
Easton, Pa............	81 "	139 "
Grand Ledge, Mich....	34 "	79 "
Hannibal, Mo........	95 "	100 "
Huntington, Ind......	51 "	75 "
Lewiston, Me......	100 "	39 "
Little Rock, Ark.	100 "	96 "
Madison, Ind...	85 "	100 "
Martinsville, Ind......	31 "	24.19 "
Plainsville, O.........	65 "	62 "
Paris, Ill..............	56 "	55 "
Topeka, Kas..........	180 "	109 "
Ypsilanti, Mich.......	80 "	72 "

Mr. Rosewater says: "Boston pays annually the enormous sum of $180 per light, while the greatest cost under public control is $100, paid by Easton, Pa." Permit me to give you a few more figures:

Alameda, Cal., 120 lights, $155; Fairfield, Ia., 6 lights, $270 per lamp; Victoria City, 15 lights, $515 (4,000 c. p.).

The replies that the authorities of Ypsilanti, Mich., recently sent in answer to the following questions may be of interest:

Q. 1. With your experience are you in favor of cities doing their own lighting? *Answer.* No.

Q. 2. Why? *A.* Political preferences and frequent changes of management are too expensive. Incompetent engineers, linemen and trimmers kept in place by a committee for political or other purposes; poor carbons, lack of attention generally, grounding of wires, breaking of globes, infringement of patents, constant repairs, etc., make this system expensive and unknown amount till the year expires. The wear and tear is immense, all kinds of complaints, and no responsible head is the rule. On the contract plan for light, you pay for what you get only, and know what to provide for in the estimate for tax levy.

Q. 3. If your city had the work to do over again, do you think they would do the same? *A.* No.

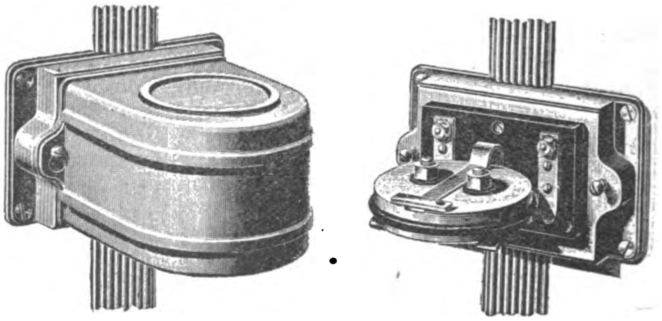
Q. 4. Has the municipal operation of your plant met all expectations and requirements? *A.* No.

I hesitate to make these corrections when the original article was written by such a well-known authority as Mr. Rosewater, of Johns Hopkins University, but it is only too apparent that municipal ownership of lighting plants is not the "rosy" side of the question after all.

THE CARDEW EARTHING DEVICE.

The accompanying engravings represent the latest pattern of the Cardew earthing device as modified by Messrs. Drake & Gorham, and adopted by the London Electric Supply Corporation. The action of the device is to connect the secondary circuit to earth automatically whenever a dangerous difference of potential is established between the lamp circuit and earth. This result is obtained by interposing some medium which will be of infinite resistance until a dangerous difference of potential exists, when a free passage for the leakage current is provided.

In the device illustrated the static arrangement is adopted, as it is found to give the best results. It consists of two brass plates placed near, but insulated from, each other. Between these lies a thin foil of aluminium, which is retained in position by ebonite pegs, one plate being connected to earth and the other to the secondary circuit. A flat projection is formed on the upper plate over one end of the foil, so that as soon as a difference of 400 volts is established, one end of the foil lifts by static attraction, and a metallic contact is made between the two plates. If there is a serious leak between the primary and secondary, and if the primary is also completely earthed elsewhere, the primary fuses in one or both of the houses in which the leaks occur are blown. These fuses will go with a current too small to cause a fire, even if one earth is through a house secondary; that is to say, if in one house the primary is in contact with the secondary in the transformer, the secondary will have been already earthed on one side by leakage. The plates are all made interchangeable, so that when the foil has acted it is merely necessary to slide in some fresh plates.



FIGS. 1 AND 2.—THE CARDEW EARTHING DEVICE.

It has been suggested that the permanent earthing of the secondary does all that the static contact will do. Earthing the middle of the secondary circuit reduces the stress on the secondary insulation, but admits of danger from fire, as it only requires one leak to earth on the secondary to make a short circuit. With the static contact two are needed.

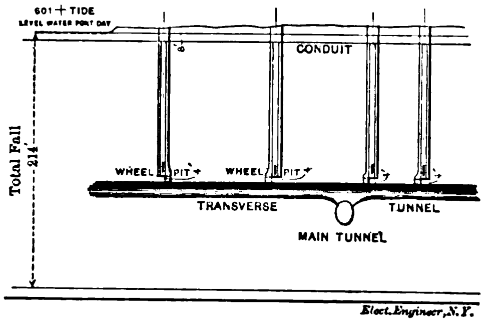
It is evident that the apparatus can be modified to act as a relay, and cut off both poles of the circuit, or to ring a bell and drop a danger disc, as has been arranged for the Chelsea Electric Supply Co., where continuous currents are used.

This apparatus has been adopted by the Deptford Co., the Newcastle Electric Supply Co., the Lynmouth Central Station Co., the Shanghai Electric Co., and others.

UTILIZING NIAGARA.

For many years past engineers and manufacturers have discussed plans for utilizing the enormous power available for manufacturing purposes in the Falls of Niagara, and since the transmission of power by electricity has become a reality, these discussions have been given renewed vigor. About four years ago a company was formed for the purpose of putting the ideas long held into practical operation, and, as a result of a thorough study of the problem involved, is now preparing to carry out its plans, as recently announced by us.

The Niagara Falls Power Co., as the organization is called, propose to adopt, with slight modification, the plans of the late engineer, Thomas Evershed, which embody the construction of a submarine tunnel from the water level below the Falls, about 200 feet under the high bank of the river, extending through the rock to the upper Niagara River at a point about one mile above the Falls, where a head of 120 feet is obtained. The tunnel thence extends parallel with the shore of the river one and one-half miles at an average depth of 100 feet below the surface of the earth, and at a distance of about 400 feet from the navigable waters of the river, with which it is connected by means of conduits or lateral tunnels.



Elect. Engineer, N.Y.

FIG. 1.—THE NIAGARA TUNNEL.

The construction to be adopted is shown in the accompanying engravings. It is proposed to construct the main tunnel of an area equivalent to a circle 24 feet in diameter. Its mouth will be located as low as high water below the Falls will permit, and it will have a descent from a point half a mile above Port Day to its mouth of one in 100, or $52\frac{80}{100}$ feet per mile. Above Port Day the tunnel will gradually diminish in size, in accordance with the number of mills which have yet to empty their tail-waters into it, until at the upper end it will be of the same area as the cross tunnels which flow into it at that point.

Sufficient land along the river has already been secured, surveyed and apportioned into mill sites fronting on the river and on the line of the proposed tunnel with ample streets and dockage, affording facilities for approach by rail or water, to accommodate 238 mills of 500 h. p. each, or 119,000 h. p. in all, which is the engineers' estimate of the capacity of the tunnel proposed to be built.

On April 1 a contract was signed between the Niagara Falls Power Co. and the Cataract Construction Co., of New York, for the construction of the work, the cost of which will amount to $3,500,000.

The officers of the company are: President, Chas. B. Gaskill; treasurer, Francis R. Delano; secretary, Alex. J. Porter; attorneys, W. Caryl Ely, W. B. Rankine; resident engineer, Albert H. Porter.

While the present plan contemplates only the direct application of the great water power at the Falls, its transmission to the city of Buffalo is now also being considered. Indeed, we may state, that for some time past Mr. Edison has been engaged on the question, and one of the plans suggested by him is the transmission of current under a pressure of several thousand volts, by means of a cable laid in the Niagara River. A canvass of the city of Buffalo has shown that between 40,000 and 50,000 h. p. is in use there at the present time which could be largely augmented by the application of cheaper power transmitted from Niagara.

FIG. 2.—THE PLAN FOR UTILIZING THE WATER POWER OF NIAGARA RIVER.

THE WARD AND SLOAN BATTERY.

BY PROF. A. E. DOLBEAR.

In The Electrical Engineer of June, 1888, there is an excellent paper on galvanic batteries, their possibilities and limitations.[1] There are numerous tables giving the calculated and observed electromotive forces due to various elements and liquids, etc., and among these the highest given for any combination is that due to magnesium combining with chlorine, namely, 3.1 volts. The calculated E. M. F. being 3.24 volts. . The highest E. M. F. obtained with zinc is 2.2 volts when combining with hydrochloric acid.

On looking over those carefully prepared tables and considering their meaning one would be quite likely to come to the conclusion that the ground had been so well worked over that it would be a waste of time for one to attempt, with common materials, to produce a cell that should be superior to those already known. Of course, if magnesium was commercially available so as to be a competitor with zinc for battery purposes, much higher efficiency could be obtained, but if one has had to depend upon zinc and common reagents, there has not been anything to encourage him to think that any improvement was possible.

For about fifty years we have had the Grove cell and the Bunsen cell, (though I think that Silliman of Yale College used this form and described it before Bunsen), these having electromotive forces of about 1.8 and 1.9 volt, respectively; and we have had the bichromate cell with 2 volts.

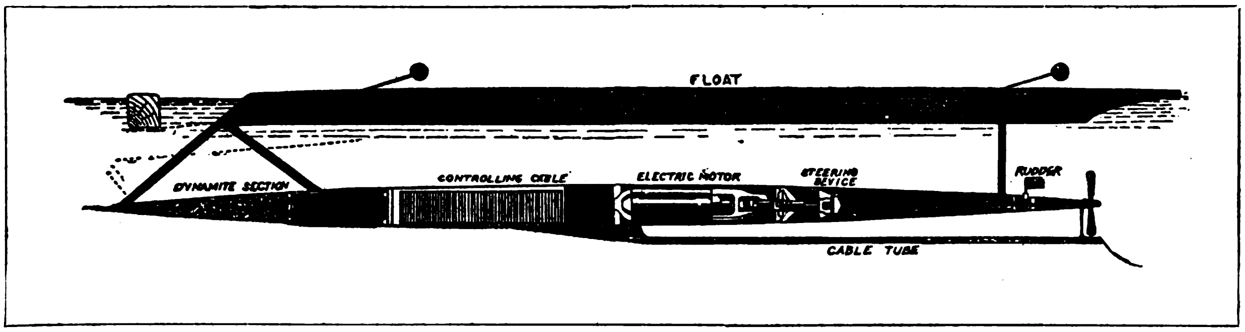
Any considerable departure from these in the way of higher electromotive force was not to be expected. Electricians will therefore be pleased to know of a galvanic cell nearly fifty per cent. better than either of those mentioned. I examined this cell some time ago and announced finding an electromotive force of 2.87 volts, whereat one of the English electrical papers declared that it did not believe it.

---

[1] The Possibilities and Limitations of Chemical Generators of Electricity. By F. B. Crocker. A paper read before the American Institute of Electrical Engineers.

As it was subject to the condition of obtaining a patent, it was at the time inexpedient to give the particulars about the cell. As that condition no longer obtains I give the directions for making such a cell and anyone may verify the statement for himself.

The zinc is put into a solution of sodium hydrate NaOH, and the carbon into a porous jar containing strong nitric acid, HNO_3, and chromic acid, CrO_3, to which is added some common salt. The proportions of these are: To one-half a gallon of HNO_3 add one and a half pounds of CrO_3 and one pound of salt. The internal resistance of a cell depends upon its size, etc., and the above quantities are for a cell 12 x 12 x 9 inches. The zincs being the equivalent of 24 rods half an inch in diameter, such as are in common use in Leclanché cells; the carbons are the equivalent of 50 electric light carbons.



THE EDISON-SIMS ELECTRIC TORPEDO.

That was the way these elements were disposed in the cells I examined. Such a cell had an internal resistance of about one-tenth of an ohm, and was capable of giving a current of 10 amperes, or more, all day. One such cell gave 10 amperes for 30 hours continuously, when its internal resistance was found to be but .13 ohm and its electromotive force 2.32 volts.

I have since that time measured such cells having 2.9 volts.

The chromic acid made from alkaline chromates is better than the ordinary, and that manufactured directly from the chromate of iron has been found to give decidedly better results than that ordinarily to be bought. The discoverers of this cell are Messrs. Ward and Sloan of Boston, who hit upon it by a system of trials with various chemicals. Such a hotch-potch would not likely be suggested by any theory of things and leads one to think it may not be unlikely that other common stuff lying round may have in it the possibility of still further increasing the usefulness of the primary battery.

TRIAL OF THE EDISON-SIMS TORPEDO.

FOR some time past experiments have been going on at the Willett's Point Government station in the trials of the Edison-Sims electric torpedo, and last week a large party, including a number of foreign army and navy officers, were invited to an exhibition of the same.

The accompanying engraving shows the torpedo in section. It consists of a cylindrical hull of copper, with conical ends, 28 feet long by 18 inches in diameter, and is supplied with a small screw and a rudder. The hull, carrying the dynamite section, controlling cable, electric motor, and steering gear, is supported at a submerged depth by an indestructible float attached to the hull by an upright steel stanchion. As the boat moves, only the top shell of this float is visible, carrying little rods showing signal flags or balls. This float, against which the Gatling and Hotchkiss guns of the enemy would be vigorously directed, is claimed by its inventor to be entirely impenetrable. The hull and float are protected from cables, ropes, or other obstructions by a sharp steel blade set at such an angle as to make the boat dive under or cut away the obstacle.

The electric current from the dynamo machine on shore is conveyed to the torpedo by a cable stored in one of its sections, which is paid out as the torpedo proceeds on its errand. The operator from his station on shore or on shipboard can at will start, stop, or steer the torpedo to port or starboard and explode the charge, which can also be arranged to explode by contact if desired, and he receives notice when the hull or blade meet with any obstruction, together with the magnitude of the same, thus making sure of the proper moment for explosion.

Owing to the great expense no torpedo was exploded during the trials, but the work done by the fixed mines viewed in connection with the operations of the torpedo boat, satisfied the visitors as to the results obtainable.

Steering is effected by a powerful electro-magnet, into which is switched the main current by means of a polarized relay actuated by the current of the shore battery. Two keys control the relay in the boat, and the rudder is thus thrown from side to side.

THE DIATHERMANCY OF AIR IN RELATION TO THE EFFICIENCY OF INCANDESCENT LAMPS.[1]

BY F. HIGGINS.

IT is occasionally useful to know something of the state of the vacuum in incandescent lamps without injuring them by perforating the bulb with electric discharges. The property which air possesses of transmitting radiant heat in proportion to its density, affords a means for obtaining this information. I have not seen any mention of this property in works on the subject which I have consulted, and do not know whether my results agree with others, which may have been obtained.

In order to make some comparative tests, I obtained, through the kindness of Major Flood Page, a number of lamp-bulbs fitted with similar filaments of platinum-iridium as nearly as possible alike in length. Some of these bulbs were exhausted to the highest possible degree, some left open to the air, and others exhausted to a pressure equal to 1-10th inch of mercury. With a sensitive thermoscope the different qualifications of the three descriptions can be made apparent. The lamps of each class being very similar in their behavior, it is only necessary to give the results obtained with one of each type. The highest possible exhaustion is that which is supposed to be the condition of the electric lighting bulbs; the 1-10th inch gives a vacuum like that necessary for the Geissler tubes; the air-bulb, as before mentioned, open to the air.

By means of adjustable resistance and batteries, the three lamps were brought to the same degree of red heat, as nearly as could be judged. The potential at the filament terminals and the volume of current flowing were measured in each case, with the result that the air-bulb required, to produce the red heat, 7.02 watts; the 1-10th inch vacuum, 5 336 watts; and the highest possible, 0.646 watts only. With the same lamps in series the highest possible becomes white hot with a current which scarcely causes visible redness in the air-bulb filament, and only dull redness in the 1-10th inch vacuum. The relative conductibility of the three bulbs as measured by radiation upon a sensitive thermoscope, was—

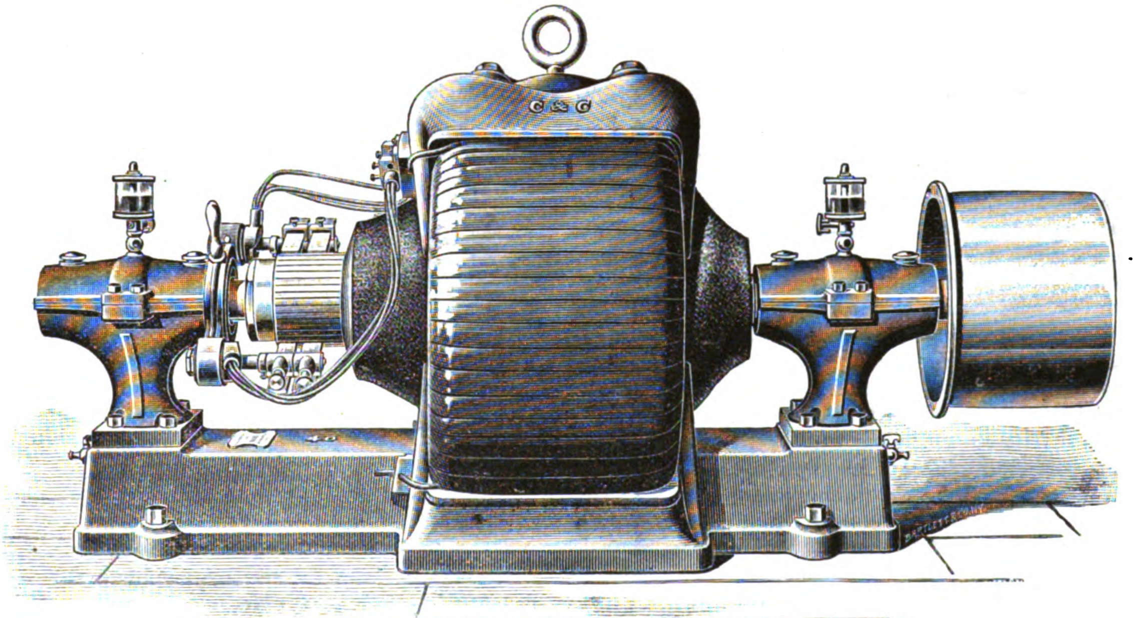
---

[1] Paper read before the London Institution of Electrical Engineers, April 10, 1890.

Air, 325°.
1-10th inch vacuum, 250°.
Highest possible, 35°.

When the same filaments were raised to incandescence, that in the air-bulb required 31.2 watts per candle; the 1-10th vacuum, 15.20 watts per candle; and the highest possible vacuum, 4 watts only per candle.

These results show that of two similar lamps, one, merely from imperfect vacuum, may require double the current that is necessary in the other to produce the same amount of light, and at the same time become dangerously hot. The two extremes of my scale show, for example, the absorption of nearly eight times the force in the case of the air-bulb that is necessary to produce the same effect in the most efficient lamp with a higher vacuum. It is possible that vacua produced by chemical absorption of carbonic gas may be more perfect even than this, and advantageous to use. There is always some air left in a vacuum produced by a pump; but it is possible to imagine that no gas will be left unabsorbed in the case of caustic potash and carbonic acid gas being employed. Lamps which differ much in the state of their surrounding medium differ also in their behavior when current is applied. Those which have a very perfect vacuum attain incandescence slowly, and lose it in the same way; while those which are imperfect start suddenly into incandescence, and as suddenly lose it.



C. & C. 25-H. P. Motor.

THE IMCHENETZKI BATTERY.

In this battery the exterior containing cell is of tinned iron, with a base of cast iron. The interior cell, open at the base, is of paraffined cardboard, and contains eight porous diaphragms. Melted paraffin wax is poured at the bottom of the first cell, and when this is cold the second is introduced. There are thus nine compartments perfectly insulated, of which four contain sulphite of soda with plates of zinc, and the other five are filled with chromic acid, with electrodes of specially prepared compressed graphite. In certain types both electrodes are of graphite. The E. M. F. of this battery is 2.12 volts, or 0.8 volt if both electrodes are of graphite. The battery, when short-circuited, gives a very constant current for several hours.

25 HORSE POWER C. & C. ELECTRIC MOTOR.

As our readers may be aware, the C. & C. Electric Motor Company of this city have for some time past been engaged in remodeling their various types of motors, and have adopted a uniform type embodying the circular form of magnet for all their standard sizes from 1 to 50 h. p.

The accompanying engraving illustrates the most approved and latest form of their twenty-five horse power motor. The most striking feature of these machines is the shape of the magnetic circuit which forms a perfect circle around the centre of the armature shaft. This construction gives the shortest possible magnetic circuit, being free from corners and projections where leakage might occur and making the motor very compact for a given power.

The advantage of this form of construction is shown by the remarkably small current absorbed by the various sizes when running either with, and without, load. This has been conclusively proven by some recent tests in New York and Chicago. The larger sizes are fitted with self oiling bearing or sight feed oil cups as desired. The speeds are relatively slow, that of the 25 h. p., here represented, being 850 revolutions per minute. A large number of these motors are already in operation in various parts of the country.

THERMO-ELECTRIC TENSION BETWEEN COMPRESSED AND UNCOMPRESSED MERCURY.

Dr. de Coudres, of Leipzig, is reported to have succeeded in detecting a thermo-electric tension between compressed and uncompressed mercury. The compression was produced either hydraulically or by means of its own weight acting through a column of mercury. It was found possible to determine with certainty the direction of the thermo-electric current, and to measure its intensity for given pressures and temperatures.

ON THE SPECIFIC RESISTANCE OF METALS AND ALLOYS.

BY GEORGE B. PRESCOTT, JR.

(Concluded from page 291.)

As Professor Jenkin points out, the values calculated from the metre-millimetre column and true specific gravity will not agree with the underlined values given in Table II., p. 291. This is no doubt due to the reprehensible practice of referring conductivities to some metal such as silver, which has rendered valuless numerous most careful experiments by skilled electricians; for no two of them take as their standard metal one with the same conductivity, nor are the relative conductivities known; so that even Dr. Matthiessen's experiments do not allow of the construction of a perfectly satisfactory table.

Briefly stated, Professor Jenkin's table was constructed by taking for its basis the resistance of a metre-gramme of lead of a certain specific gravity, as given by Dr. Matthiessen, in Table I, and calculating the values for the other metals from their relative conductivities, as also determined by Dr. Matthiessen, by taking such specific gravities as he considered the most reliable. It has been shown above that the values so obtained do not agree with the actual measurements made by Dr. Matthiessen, of silver, coper, gold, mercury, and the gold-silver alloy, and this difference may be partly due also to the fact that the wires experimented on by Dr. Matthiessen had a different density than those Professor Jenkin employed.

Dr. Matthiessen's own values for the relative conductivity of the metals and alloys (presumably the values employed by Professor Jenkin in constructing his table) together with the specific gravities and equivalents of the metals which he uses in his experiments, are given in Table III. This has been compiled from two tables contained in an original communication[1] by Dr. Matthiessen, with the exception of a few numbers not given there, which have been derived from Professor Jenkin's Cantor lectures in the B. A. report. On comparing Tables II. and III. the marked difference between the specific gravities used by Dr. Matthiessen and Profesor Jenkin will be observed.

The German silver wire which was used by Dr. Matthiessen as the standard of comparison in all of his experiments, is commonly referred to in the text books as the "alloy usually used for resistance coils," and its composition is never mentioned, although that of all other alloys is carefully stated. This omission has been rectified in this table, and the proportions of its constituent metals as analyzed by Dr. Matthiessen are given.

In a later paper[2] Dr. Matthiessen has himself prepared some resistance tables, based on assumed specific gravities and calculated from his determinations of the relative conducting powers of the metals and alloys as compared with pure silver, and from the actual resistance which he found for hard drawn wires of silver, copper, gold and the gold-silver alloy, and for lead and mercury. The figures from two of these tables have been combined in Table IV. It will be noticed that while the metre-gramme column in this table corresponds in the main with Table I., there is a slight difference in the figures for mercury and a greater difference in the figure for silver. Accounting for this discrepancy by the fact that the silver wire used was drawn in a peculiar manner, Dr. Matthiessen proceeds to give another table (Table V.) which was calculated by taking the conductivity of the gold-silver alloy 7.148 = 15.03, and the resistance of a metre-gramme as 1.668 B. A. units; and obtaining the resistance of the other metals from their relative conducting powers as given in Table III. This results in a different value for the conducting power or resistance of silver and mercury than would be obtained by calculating these values from Table IV.; for, if the specific conducting power of silver, 48.83, as given in Table IV. is taken as 100, then the specific conducting power of the gold-silver alloy as given in that table would be 14.64, a difference of 2.6 per cent.; which is too great to be accounted for by the difference between the two values for silver.

Although there does not appear to be any explanation of this discrepancy except that Dr. Matthiessen preferred the earlier determinations, it would seem as if the figures in Table V.. should be taken as representing the values which he would give for the specific resistance of the metals according to his determinations. If the value 0.1682 which is given in Table I., for the resistance of a metre-gramme of hard silver be reduced by using the specific gravity 10.5, then the resistance of a metre-millimetre will be 0.0204, which agrees very closely with Table IV., while both differ by about 2.3 per cent. from the figure in Table V. It seems probable that these differences may have arisen from calculating the resistances from the relative conductivities of the metals as compared with those of silver and the gold-silver alloy.

TABLE III.

Relative Conducting Power, Specific Gravity and Equivalents of the Metals Experimented on by Dr. Matthiessen.

From Philosophical Transactions, 1864.

Metals.	Specific gravity.	Equivalent.	Conducting power.
Silver, hard	10.468	108.	100.00
" annealed			108.57
Copper, hard	8.95	31.7	99.95
" annealed			102.21

Gold-silver alloy, hard	15.18§		15.03
*German-silver, hard or annealed	8.74§		7.8§

* By analysis volumes, per cent., Ni, 12.84; Zn, 36.57; Cu, 50.59.
† Calculated from the impure metals by Dr. Matthiessen.
§ Jenkin's Cantor lectures.

If mercury is taken as the standard the differences are still more marked, and Professor Jenkin found that the disagreement between a London and Berlin Siemens mercury unit was as great as 1.6 per cent. The re-determination of the value of the ohm in terms of the resistance of mercury has served to still further increase the discrepancies, when comparison is made between the new value and the earlier determinations of the specific resistance of mercury.

Siemens' determinations of the resistance of mercury were made for given weights and lengths and converted to resistance per unit volume by using the specific gravity 13.557. The B. A. committee found that 1 B. A. unit = 1.046 Siemens 1864 unit, when corrected by using the specific gravity, 13.595, from which it follows that a column of mercury 1 metre long and one square millimetre section (=1 Siemens unit) has a resistance of 0.9537 B. A. unit. In terms of the B. A. unit, therefore, the specific resistance of mercury (cubic-centimetre) = 95,370 C. G. S. units. By the definition of the 1884 Paris Congress a column of mercury 106 centimetres long and 1 square millimetre cross section at 0°C. has a resistance of 1 legal ohm, according to which the specific resistance of mercury = 94,340 C. G. S. units. Therefore,

1 legal ohm = 0.9889 B. A. unit.
1 B. A. unit = 1.0112 legal unit.
Difference 1.12 per cent.

According to Matthiessen (Table IV,) the resistance of a column of mercury 1 metre long weighing 1 gramme at 0°C. = 13.071 B. A. units. Taking the specific gravity = 13.595 the specific resistance in terms of the B. A. unit is found to be 96,146 C. G. S. units ; from which it follows that—

---

[1] Philosophical Transactions, 1864.

[2] Philosophical Magazine, 1865.

1 B. A. unit = 0.98122 legal ohm .
1 legal ohm = 1.0191 B. A. unit.
Difference 1.88 per cent.

As given in Jenkin's table the specific resistance of mercury in terms of the B. A. unit is 99,740 C. G. S. units, and comparing this as before, with the Paris value,

1 B. A. unit = 0.94586 legal ohm.
1 legal ohm = 1.0572 B. A. unit.
Difference, 5.46 per cent.

It is now possible from the information so far obtained, to trace the source of the disagreements between the various electrical text books: In Maxwell's *Electricity and Magnetism*, Table IV. is copied from the *Philosophical Magazine*, and a column added, giving the specific resistances in C. G. S. units. In Everett's *Units and Physical Constants*, Maxwell's table is copied, and in the later edition of this work (1886) the values are corrected to legal ohms by subtracting 1.88 per cent. (derived as above,) from the numbers in the specific resistance column, excepting mercury, which is valued according to the Paris definition. On the following page two of the columns from Jenkin's table are given, the numbers having been corrected by subtracting 1.88 per cent. in the same manner, mercury excepted as before. The juxtaposition of these two tables, both based on Matthiessen's experiments, makes their disagreement glaringly conspicuous.

Stewart and Gee, in their *Practical Physics* also extract two columns from Jenkin's table in terms of B. A. unit without reduction, although the book appeared as late as 1887. In Ayrton's *Practical Electricity* the same two columns are also taken from Jenkin, and the numbers reduced to legal ohms by multiplying each by the constant 0.9889, obtained as explained above; but here also the value for mercury has been altered to correspond with the definition of the legal ohm.

TABLE IV.

Specific Resistance of the Metals in B. A. Units at 0° C.

Compiled from Paper by Dr. Matthiessen in *Phil. Mag.*, 1865.

Metals.	Specific gravity.	Resistance per metre gramme.	Hard drawn round wires 1 metre long, 1 millimetre diameter.	
			Resistance.	Conducting power.
Silver, hard drawn	10.50	0.1689	0.02048	48.83
Copper, " "	8.95	0.1469	0.02090	47.85
Gold, " "	19.27	0.4150	0.02742	36.47
Lead pressed.....	11.391	2.257	0.2527	3.957
Mercury, liquid...	13.595	13.071	1.224	0.8172
Gold-silver, alloy, of the wire. ...	15.218	1.668	0.1399	7.148

In the new small edition (1889) of Gray's *Absolute Measurements* Jenkin's table is reprinted in full and corrected to legal ohms by subtracting 1.12 per cent. from all the numbers with the exception of those for mercury, which is reduced by some arbitrary constant to have a specific resistance of 95,110 C. G. S. units. On another page Professor Gray gives a table of the resistance of pure copper wires drawn to the English standard gauge which has been calculated by taking 1.624 C. G. S. unit as the resistance of a cubic centimetre of hard drawn copper, as given by Matthiessen in the *Philosophical Magazine*, (Table IV.) A foot note to the Jenkin's table says :—" According to the determination of the specific resistance of mercury referred to above (viz.: 106 centimetres, 1 square millimetre = 1 legal ohm) the value given in this table is about 0.8 per cent. too high." And again :—" The value given in this table in column I. (cubic centimetre) for hard drawn copper, has evidently been calculated from the corresponding observed result in column III. (metre-gramme,) by using the density 8.89 for copper, and is, therefore, higher than that on which the standard wire table is founded."

There is also a typographical error in the Jenkin's table as given in this book, the resistance of a cubic centimetre of hard copper being given as 1,534 instead of 1,634 C. G. S. units. Another misprint in the foot note states that the length of a column of mercury having one B. A. unit resistance is 0.1048 centimetres instead of 104.8 centimetres, as it should be.

It may be mentioned also that a table of the resistance of annealed pure copper wires drawn to the English standard wire gauge, which was printed by the London *Electrician*, and a similar table for the American gauge compiled by the writer, both published several years ago, were founded on the resistance of the Matthiessen standard mile unit as defined in the B. A. report. This happens to be the lowest of all the figures for copper, and more nearly corresponds with later observations than any of the others.

In order that these conflicting figures may be conveniently compared, those for silver, copper, lead and mercury, as found in the various books referred to, have been reduced to legal ohms, and will be found in Table VI.

The facts brought to light by this investigation not only explain the causes of the conflicting values for the resistance of metals now current, but seem to indicate as well, that even Dr. Matthiessen's researches are not all that could be desired. In fact it is not infrequently the case that samples of commercial copper wire on being subjected to careful tests, have been found to actually possess a higher conductivity than that assigned to absolutely pure copper. Numerous instances of this fact were given by Willoughby Smith, some years ago, in a communication addressed by him to the Society of Telegraph Engineers, in which some samples came out four per cent. in excess of the standard of pure copper.

TABLE V.

Specific Resistance of the Metals and Alloys in B. A. Units. Calculated by Dr. Matthiessen, Taking Conducting Power of Gold-Silver Alloy 7.148 = 15.03.

From *Phil. Mag.*, 1865.

Metals.	Round wires, 1 metre long, 1 millimetre diameter.	
	Specific conductivity, 0° C.	Specific resistance, 0° C.
Silver, hard....................	47.56	0.02103
" annealed	51.63	0.01937
Copper, hard..................	47.53	0.02104
" annealed	48.61	0.02057
Gold, hard.....................	37.06	0.02697
" annealed	37.73	0.02650
Aluminium, annealed..........	26.66	0.03751
Zinc, pressed..................	13.80	0.07244
Platinum, annealed............	8.58	0.1166
Iron, annealed.................	7.99	0.1251
Nickel, annealed...............	6.23	0.1604
Tin, pressed....................	5.88	0.1701
Lead, pressed..................	3.96	0.2527
Antimony, pressed............	2.19	0.4571
Bismuth, pressed..............	0.591	1.689
Mercury liquid................	0.788	1.270
Platinum-silver alloy..........	3.18	0.3140
German silver..................	3.71	0.2695
Gold-silver alloy............ ...	7.148	1.668

Note: The sp. grav. of copper used was 8.95. Siemens found it to vary for a wire between 8.89 and 8.92 ; using the value 8.91 the conducting power would be 47.64.

The writer some time ago[1] suggested that it would be a very desirable thing if some institution with facilities such as are possessed by the Johns Hopkins University, would undertake the re-determination of the resistance of copper, prepared by modern process of manufacture. It now seems even more desirable than ever that some competent electricians should repeat Dr. Matthiessen's experiments, taking care, however, to avoid the errors into which he fell.

One other matter which it is pertinent to touch upon in connection with this subject, is the work done by Dr. Matthiessen and his colleagues in determining the effect of temperature on the resistance of metals. While the text books usually give a mean formula derived from his experiments, taken from Jenkin's Cantor lectures in the B. A. reports, it does not appear to agree with the mean formula given in Dr. Matthiessen's original

1. Reduced to legal ohms by multiplying by .9889.
*Corrected for temperature by Matthiessen's formula for pure copper.

paper[2] on that subject. Table VII. is taken from the paper referred to as embodying the results of these researches.

TABLE VII.

Conductivity of the Metals at t° C.

$$c_t = c_0 \, (1 - at + b\,t^2).$$

Conductivity at 0° = 1.

From Dr. Matthiessen's Experiments, *Phil. Trans.*, 1862.

Metals.	Conductivity at t° C.
Silver............	$1 - 0.0038287\,t + 0.000009848\,t^2$
Copper.........	$1 - 0.0038701\,t + 0.000009009\,t^2$
Gold..	$1 - 0.0036745\,t + 0.000008443\,t^2$
Zinc......	$1 - 0.0037047\,t + 0.000008274\,t^2$
Cadmium.........	$1 - 0.0036871\,t + 0.000007575\,t^2$
Tin.....	$1 - 0.0036029\,t + 0.000006136\,t^2$
Lead.............	$1 - 0.0038756\,t + 0.000009146\,t^2$
Arsenic...........	$1 - 0.0038996\,t + 0.000008879\,t^2$
Antimony....... ...	$1 - 0.0039826\,t + 0.000010364\,t^2$
Bismuth..........	$1 - 0.0035216\,t + 0.000005728\,t^2$
Means.........	$1 - 0.0037647\,t + 0.000008340\,t^2$
Iron...........	$1 - 0.0051182\,t + 0.000012916\,t^2$

The value of the constants a and b, for calculating the resistance of pure metals at t° C., when their resistance at 0° = 1, may be obtained by taking the reciprocal of the above formula, thus:—

$$\frac{1}{1 - at + bt^2} = 1 + at + (a^2 - b)\,t^2.$$

$$\therefore\ r_t = r_0\,[1 + at + (a^2 - b)\,t^2].$$

Thus the formula for pure copper would be—

$$r_t = r_0\,(1 + 0.0038701 + 0.000005969.)$$

The above formulæ, excluding that for iron, agree closely, from which fact Dr. Matthiessen thinks that the law may be deduced that all pure metals in a solid state vary in conducting power between 0° and 100° to the same extent; more especially as he found that wires of one and the same metal showed almost the same differences as were found between the mean results obtained for the different metals.

WATER POWER UTILIZED AT WATSONVILLE, CAL.

One of the best examples of the utilization of waste water that has come under our notice, says the *Mining and Scientific Review*, is that recently made at Watsonville in California. The Corillitos Water Co. of that place get their supply from Corillitos creek, at a point 7½ miles from the town. Their distributing reservoir is located 1½ miles distant at an elevation of 90 feet. The water is brought from the Corillitos creek six miles above, in a 15-inch pipe, and discharges into the reservoir under a considerable head. It occurred to the water company not long ago that this pressure might be used to light the town, and after conference with the Pelton Wheel Company, of San Francisco, the scheme was found to be perfectly practicable and a contract was at once entered into with that company to erect the power plant, and with the Thomson-Houston Co., for the electric installation.

The plant consists of a 4-foot Pelton wheel, which runs under a pressure of 60 pounds, equal to a head of 140 feet, the water being discharged on to the wheel through a 2¼-inch nozzle. Close regulation is afforded by a deflecting nozzle and hydraulic governor, which gives perfect steadiness to the lights. The dynamo is a T. & H. alternating current, which runs 300 16-candle power incandescent lights, the current being carried to the town, 1½ miles distant.

The power thus furnished, it will be seen, is from the waste water that has heretofore been absolutely valueless, and is so much clear gain to the company, the cost of operating the plant being almost nominal. The water after leaving the wheel falls into the reservoir, having been areated and freshened to as great an extent as though it had been dashed over a cataract, thus incidentally accomplishing without expense just what is so much needed in such cases. This plant has been in successful operation some three months, and it is now proposed to put in an ice machine and thus utilize the power wasted during the day. There are probably hundreds of places all over the country where this same experiment can be repeated with corresponding results.

---

[2] THE *Philosophical Transactions*, 1862.

THE GILLETTE MAGNETO BELL.

The care and attention required by electric batteries has made the magneto a favorite generator, as it is always ready for action and can be applied to a variety of purposes besides a calling instrument. One of the recent forms of this kind brought out is the Gillette magneto, made by the Shaver Corporation of this city. It is illustrated in the accompanying engraving, Fig. 1. The great powers of this magneto are due largely to the shape of the steel magnets. These as will be seen in Fig. 2., consist of a single round piece of steel having interior pole-pieces which are brought into close proximity to the armature. Three of these magnets are bolted together to form a single strong magnet, which entirely prevents the straying of the lines of force by concentrating them on the armature. The latter consists of a soft iron core, wound with a bobbin of wire on either end and which is revolved at high speed by the gear wheels and crank shown.

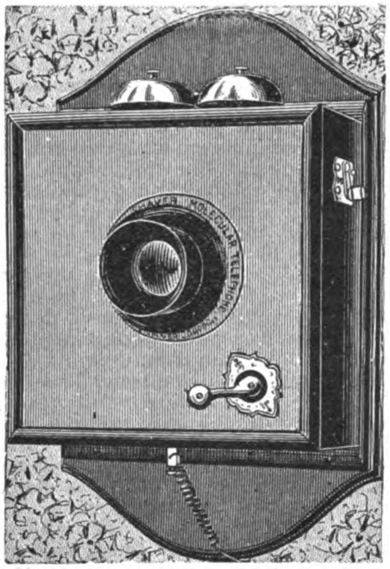

Fig. 1.—The Gillette Magneto.

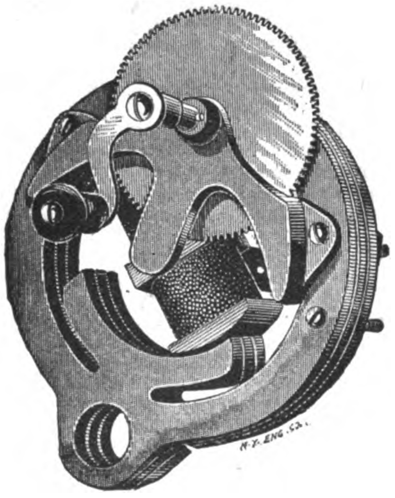

Fig. 2.—The Gillette Magneto.

The Gillette magneto is substantially made and is capable of ringing a bell through several thousand ohms resistance.

THE SOLANO HIGH SPEED REVERSIBLE ENGINE.

The practice of connecting engines direct with the shafts of dynamos is coming more and more into vogue, and engine builders are giving considerable attention to this feature. Messrs. Howard & Morse, of this city, have adapted the Solano engine to this new field after having operated the same successfully for some time on other classes of work.

The engine which is illustrated in two views in the accompanying illustrations is of the three cylinder, single-acting high speed type, and its principal feature consists in the rotary steam valve which forms but a single piece.

The receiving chambers of the rotary valve are alike; also the ports in the valve for distributing the steam. Thus, when the engine is going in one direction, the steam is admitted to one of the receiving chambers and exhausted out of the other; when the direction of the engine is reversed, the steam is admitted into what was the exhaust chamber before, and the exhaust takes the opposite chamber. To accomplish this, a steam valve controlling the direction in which the steam may be turned is employed; the other is the exhaust valve controlling the direction from which the exhaust shall flow. The two valves are connected by a link so that the movement of one is transmitted to the other, both moving together.

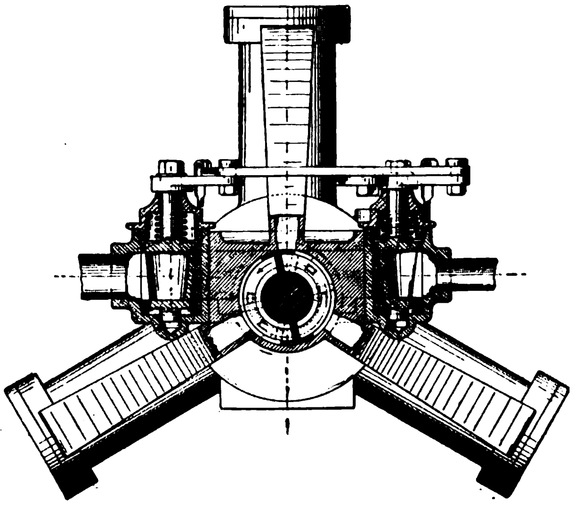

Fig. 1.—The Solano Engine.

The operation of the engine is very simple; the steam flows from the steam pipe into the steam valve, which is nothing more than a three-way cock, which, when it is in the central position of its travel, is entirely closed, stopping the engine; but, when moved in either direction the steam flows into one of the receiving chambers of the rotary valve moving the engine in the direction corresponding to that chamber. At the same time the exhaust valve which is connected to the steam valve, or cock, and which is of the same construction, turns so that the exhaust will take place from the opposite receiving chamber in the rotary valve to which steam has been admitted. Thus the direction in which the engine shall turn is simply controlled by the direction in which the steam is turned on.

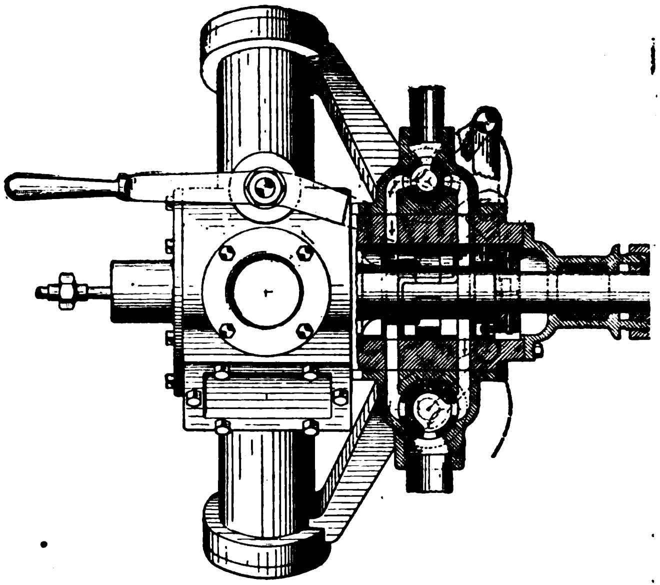

Fig. 2.—The Solano Engine.

Another important feature of the engine is that the exhaust passage in the controlling exhaust valve is such that no matter how much or how little steam the steam valve may allow to pass into the cylinder, the exhaust passage is always proportionately large, thus insuring a perfetly free exhaust at all times.

The engine is well built throughout and is provided with a sensitive governor, the engines being capable of working up to 400 revolutions per minute.

The engines have been adopted on board the Savannah Line steam ships, and the Beaver Line of Montreal has twenty of them in use at present, driving fans for obtaining draft in the boiler rooms.

SINGLE AND DOUBLE TROLLEY WIRE SYSTEMS FOR ELECTRIC RAILWAYS.[1]

BY G. W. MANSFIELD.

IN addressing you this evening on the subject of "Single and Double Trolley Wire Systems for Electric Railways" I shall endeavor to place before you precisely the advantages and disadvantages of each system. The other day while studying over the subject, the following questions arose in my mind :—Why should I spend any time whatever in discussing the two systems? Is it necessary? If so, why? I think my telephone friends here could answer that question perhaps.

I read Mr. Denver's paper with mingled pain and pleasure,—pain on account of his sufferings, and yet pleased to learn, clear at the end of the paper, that he had a remedy. The antagonism of the telephone companies to the single wire system has become universal and their love for the double wire system proverbial. This opposition has provoked much discussion and led to deep thought. My own thinking and experience has forced me to the solid conviction that for an efficient electric railway system which can be universally used, the single trolley wire is the only one to be considered. Being then, of this conviction, the time I spend upon the double trolley wire system is purely educational for my dear friends in the telephone companies and I trust I merit their hearty applause since they all tell me they want electric railways and the best,

The principles involved in the construction of a single trolley wire system are familiar to you all. You know that it can be done successfully and is done successfully. Do you, or does anyone, know that under all the conditions under which the single trolley wire works successfully the double telephone system will also work successfully?

If the difficulties with the single system have all been overcome and those of the double system have not, let us consider what we must take into account to make the latter equal the former.

With the double system the weight of the second wire, the insulators, frogs, crossovers, etc., the double liability of sleet and ice accumulating on the two wires, and the high winds all necessitate larger and stronger poles and stronger span, pull-off and anchor wires, etc. This increase in size and number of wires means additional unsightliness, a larger original outlay and an increased expense for maintenance.

One of the chief troubles which an electric railway has to contend with is to keep its trolley wire free from snow and ice during the winter months. Prompt and energetic action, with a greased trolley wire has saved the single trolley roads from any serious delay. If these same roads had had two wires to clean, I have no question but that their service would have been seriously impaired, if not entirely stopped.

I do not think that the question of traction is one of any serious moment. The rails must be cleaned for adhesion and for the cars to keep on the track irrespective of whether the single or double trolley wire system is used, and as they are get-at-able they are comparatively easily taken care of. It is simply a question of management, muscle and salt, and with improved electric sweepers and plows, there never need be any great difficulty in keeping the cars running on schedule time. The problem, however, of cleaning sleet frozen to a trolley wire placed 18 feet above ground in a large city or even on a country road is a most annoying and troublesome one.

One, if not the greatest difficulty, which would have to be overcome with the double trolley system, is the liability to leakage. The two wires hanging side by side upon the same span wire need the best of insulators. Considering all the atmospheric conditions and the possible accumulations of sleet and snow it unquestionably would be more difficult to maintain good insulation between the two wires than it is between the single wires and the ground. With the latter system you have far greater opportunities to introduce additional insulation. It can be cut into the span wire or placed on the pole, whether it be of iron or wood.

So far the under-running double wire roads have had the wires placed either six inches or eighteen inches apart. The Daft roads employ the former distance, while the Thomson-Houston Company in its attempts at Cincinnati used the latter distance. Both methods have their objections. If the wires are placed too near, strong winds may swing them together, causing short circuits. In one place the short circuit was so heavy that the wires were melted and fell into the street. With the wires farther apart plainly this trouble would not exist. With the wires close together a single trolley arm can be used. but a double trolley fork and two wheels are necessary. These wheels must be thoroughly insulated whether they rotate upon a separate or upon the same spindle. The maintenance of an insulation sufficient to withstand 500 volts under such conditions is surely not an easy task.

With the wires further apart the necessity of more than one frog at the crossings and turnouts is necessary, which is objectionable, and more than one trolley arm would have to be used. The maintenance of these trolley arms, the difficulty of keeping them on the wires, and their weight upon the roof of the cars are all serious objections. In the single wire system, questions of weight, insulation of trolley wheels, etc., practically do not enter.

Another serious objection to the double system is in the overhead switching. The placing of overhead frogs even on the single wire system requires the greatest exactitude and care, so much so that on many roads it has been found necessary to train a special gang of men to place and look after their adjustment. The expansion and contraction of the wires, and the giving and taking of the poles are constant sources of annoyance and trouble in keeping the frogs and insulators in place. The expansion of copper is about ⅓ inch per degree for 1,000 feet, or ⅝ of an inch per mile for each degree of change in temperature. If the temperature changes, as it often does, twenty or thirty degrees in a day, the trolley wire might expand or contract fifteen or twenty inches per mile. With the double trolley wire system the location and maintenance of the frogs and the cross-overs and turn-outs would, in view of these circumstances, be an extremely difficult one. They would require constant adjustment and readjustment, and if the method of placing the trolley wires 18″ or more apart was employed, so that a large number of frogs was introduced, it would practically be a determining factor between the possible and the impossible system.

On complicated systems of double track lines, the number of insulators and frogs for the double wire system would be very large. I have frequently studied such systems and have found that it is by no means a rare occurrence to meet arrangements of tracks that require from 25 to 50 overhead frogs and insulators, and in some instances from 125 to 150. The small blue prints which I have here indicate clearly what I mean. The weight of all these necessarily demands a most substantial overhead construction, and undoubtedly the only thing that could be done would be to erect large and substantial trusses. It must be also evident that the difficulty of keeping the trolley wheel upon these wires is largely increased, and also the liability of some of the ends breaking loose from a frog and falling.

Imagine such a network of wires loaded with ice on a winter's morning. Add to these wires, if you will, the necessary guard wires, and it is as essential to put up guard wires, with the double system as for the single, and I for one would not have sufficient audacity to argue for the same before a city council. It can also be clearly shown that the wires of the same polarity of the double system will not in all conditions correspond when they are attached to the frog. To illustrate what I mean, take the single track Y. If a sketch of this is made on the double wire system, it will be seen that if the right hand wire is a positive wire and the left hand wire a negative wire on a straight piece of track, and they are carried around the Y on to a branching track, the positive and negative leads are bound to conflict. Under such circumstances either the current must be broken on the motor when the car passes that point, or there will be bad flashing in the switch.

It is practically impossible to construct a frog for such a place that will permit the trolley wheels to roll across, taking current from the same continuously. There will have to be a break in the continuity of the circuit at the frog for a certain length of time. This break means the going out of the lights every time the car passes such a frog. With the single wire system, none of these difficulties are experienced. On large roads the cost of copper necessary for the double wire system would be so great as to be almost prohibitory. With the single trolley system, the earth being used as a return circuit, we obtain the aid of its conductivity and also that of the rails. Practice has demonstrated that with such an enormous conductive area the resistance of the return circuit can practically be considered *nil*. It is true that the supplementary wire of a size equal to the trolley wire is run through the earth and connected to each rail. The use of this conductor is twofold. It not only forms a good ground for each rail but it ties the whole underground system into one connected and complete metallic system. Counting the resistance of the earth as zero it is readily seen that only one quarter of the copper wire is necessary for the single system as for the double wire system. Hence a most decided saving is possible.

On a large system the subject of feeders always is a most important one. With the single trolley system it is only necessary to feed one-half of the circuit, whereas with the double trolley system it is necessary to feed both sides of the circuit. In this direction alone, therefore, the cost of the latter system must be four times that of the former, allowing for the same percentage of loss.

In regard to guard wires, I see no reason why it is not practically as necessary to place them over a double wire system as over a single. With the current passing out over one wire down through the car, through the motors under the car and back by the other wire, the chances of leakage are very great.

It would be very difficult to prevent leakages somewhere on such circuit. If a leakage should be established on the positive side of a motor armature on one car and on the negative of another, both of the cars and the station might be damaged. If these leakages are so liable, the danger from a foreign wire falling across either one of the trolley wires still exists. It is unfortunate, but nevertheless true, that arc light wires which are supposed to be thoroughly insulated from the ground, leak at times sufficiently to cause damage to life and property if a telephone or telegraph wire happens to fall across them. With bare trolley wires and with the increased chances of leakage surely the city authorities would not and ought not to permit the erection of the double trolley system without the same system of guard wires over them as is placed over the single trolley system. The expense incumbent upon the railway company in this direction therefore is equal for both systems. The danger to property in my opinion is practically equal in both systems.

---

[1] Read before the Boston Electric Club, April 28, 1890.

I do not deny the fact that it is possible to so construct a simple double trolley system that a falling wire touching one of the trolley wires and with its other end on the ground, would deflect no current, nor would I deny that under similar conditions a man touching this fallen wire and standing upon the ground, would receive no shock. This is speculation, not fact, and I am not arguing this matter from a theoretical or a possible condition of affairs, but from the results of practice which teach that ordinary existing circumstances always militate against the ideal, giving as a resultant, a system materially different from what we supposed it would be.

Repeating, therefore, what I have said in regard to danger to life and property, I feel that the danger question is practically equal in both systems.

It is unnecessary for me to state to you the fact that 500 volts is not dangerous to life since I think there is no question but what you all have taken such a potential, if not higher, and I should be pleased to have any of you state, if a discussion follows this paper, whether you have taken this potential or a higher one, and the attending circumstances.

As to the relative expense of the two systems, leaving out the question of feeder wires, it is true that practically in every case the double trolley system would cost one-half as much more, if not twice as much, as the single trolley system. It may be here stated that the expense of running the supplementary wire underground is sometimes heavy. True, it is, but the expense is largely dependent upon the street through which your track passes. If it is macadamized or paved with Belgian blocks, or with any paving stones, the expense of the removal and replacement of the same would be large. Such conditions of streets, however, exist only in large cities, and here I believe it is generally conceded by friends and opponents that the double trolley system is entirely out of the question; the expense however would nowhere nearly equal the additional expense of the feeder wires for the double system, nor would it equal the cost of the maintenance of such a system for a year or two.

If, on the other hand, I admit that it is possible, but not the best system for a small road, we are happily confronted by the fact that so far in the majority of the cases, the small roads are not where it is needed, since the telephone companies, which practically represent the only opposition to the introduction of the electric railway, have not so extensive lines in these places. It is therefore the unfortunate middle man that has to suffer. In answer to all the foregoing objections to the double trolley wire system, the statement is sometimes made that there are to-day double trolley roads operating commercially successful; and that if they can operate in one place there is no reason why they can not be made to operate in all other places. Steam dummies are used to-day in some places; why do not railroad companies use them everywhere? There is scarcely anything impossible in this practical age of ours, and therefore I do not deny that the double trolley system could not be placed anywhere that the single is placed, but I unhesitatingly state and know that it could not be placed wherever the single is placed, and prove equally as satisfactory and commercially successful. It is not a question of cost but one of expediency and practicability. The electric companies would build double systems if they could guarantee them, and the railroad companies would demand them if they had confidence in them. An unbiased thinking man is forced to adopt the single system.

History shows that the efforts of the early promoters of the electric railway were to develop a double wire system with an over-running trolley. This has proved a signal failure. The only roads so operated to-day are at Easton, Pa., Elkhart, Ind., Ithaca, N. Y., Lima, Ohio, Pittsburgh, Pa., Sunbury, Pa., St. Catharines, Ont., Lancaster, Pa., Asbury Park, N. J., Appleton, Wis., and Wheeling, W. Va., eleven in all. There are none under contract, and no firm thinks for a moment of building such a system. History also shows us that the next step in progression was the development of the under-running trolley for this same double trolley wire system. Years have gone by, and we have only three companies in the whole United States having such a system in operation: these are the ones at Cincinnati, O., Meriden, Ct., and Mansfield, O. As illustrative of the feeling and confidence the street railway profession have in this system, I find there are but five companies who have contracted for such a system. I venture to assert at this point that if the conditions of the contracts for these roads were seen, most interesting and extraordinary clauses would be discovered.

If we now turn to the extraordinary development of the single trolley system, we find figures which are truly amazing. On July 1, 1888, the Thomson-Houston Company was not in the electric railway business, and the total number of roads in operation in the United States and Canada, put in by all of the electric companies who were then doing business, viz., Sprague, Daft and Van Depoele, was 33. Of these but two or three were the single wire system under-running trolley; whereas to-day there are nearly 115 roads in operation, and an equal number under contract, and of these all but some four or five have been put in or contracted for by either the Thomson-Houston company or the Sprague company. Two hundred and thirty roads contracted for the single system, five for the double. If I take the history of the Thomson-Houston company since it commenced to build electric railways, I will find that it has in less than two years put 61 roads in operation, and has under contract 45 more, making a grand total of 106 roads contracted for with the single trolley system, by one company. Could there be more conclusive proof of the pre-eminent adaptability to a commercial neccessity than this is, for the single trolley system?

The future is destined to surpass this record as surely and as amazingly as the adoption of electric lights and telephones surpassed their records of eight or ten years ago.

ELECTRIC RAILROADS IN THE CENSUS.

The use of electricity as a motive power for street cars will be an important section of the Census investigation of the electrical industry. None of the many forms of the application of electricity has been developed more rapidly or accompanied by more satisfactory results than that of the transmission of power for street car purposes.

The Census investigation of the general subject of transportation, has been very properly assigned to Professor Henry C. Adams, statistician of the Interstate Commerce Commission. He has divided the subject into several sections, one of which is "Rapid Transit in Cities." This section has been assigned to special agent Charles H. Cooley, a son of Thomas M. Cooley, chairman of the Interstate Commerce Commission.

The plan of investigation that has been adopted, is designed to make a comparison between the different motive powers employed,—animal, steam dummy, cables and electricity,—to show the relative economic value of each. Electricians can wish for nothing better than this. The only danger is, that they will experience from it an embarrassment of success. Street railroads are now being transformed into electric roads as fast as manufacturers and construction companies can take care of the business. How they will manage with an added impetus given to the business, is hard to predict. We are now witnessing the fulfillment of a prophecy made in 1889, regarding the adoption of electric motor power by all street car roads in the country.

"*The change will not be a development. It will be a transformation.*"[1]

If the investigation by the Census Office of the relative economic value of the motive powers now in use for street car service, results as I believe it will, the "horse car horse" will disappear. The places that know him now will know him no more.

The schedules for the section of rapid transit in cities will include the inquiries to be made regarding electric railroads. That part of the schedules pertaining to the electrical branch of the subject, will be prepared under my supervision, and that portion of the report pertaining to the uses of electricity as a motive power for street cars, will be embodied in my report on the investigation of the electrical industry, as well as in the report of the section making the investigation.

The Census Office is performing a service of great value for the public in making such special investigations. All who have to do with questions of municipal management or public affairs, are keenly aware of the necessity of securing reliable data by which to guide their actions. The cost of obtaining such statistics through the Census Office, is but an infinitesimal tax on the capitalization of the industries interested, while its impartial and impersonal character gives it the weight of an unquestioned authority.

Mr. Cooley is anxious to have electric railroad men impressed with the great help they can give him by filling out and returning their schedules promptly. I tell him that he will find in this, as in all other matters, electrical men lead the world. They can't help it. It is the nature of the "fluid" they imbibe to make them "quick as lightning."

ALLEN R. FOOTE, *Special Agent.*

.... THERE can be no possible argument in favor of speed as against legibility and accuracy in telegraphic work. Performances like Pollock's are, in my opinion, valueless.—*G. G. Ward.*

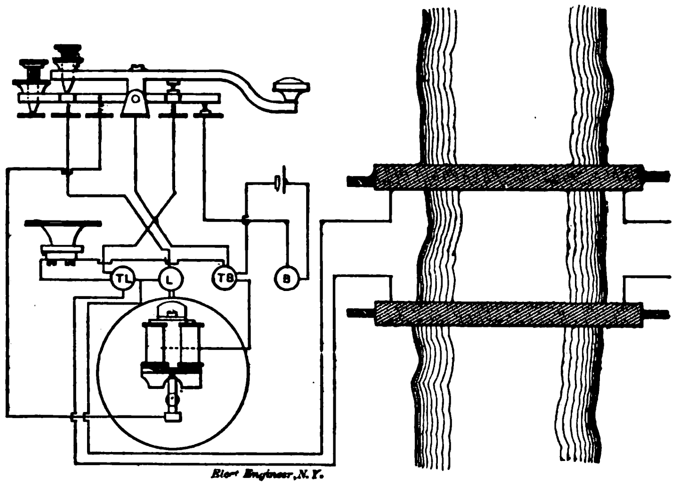
ON SIGNALING ACROSS RIVERS IN INDIA.[1]

BY W. F. MELHUISH.

It not infrequently happens that a river cable fails entirely, or becomes imperfect at a time when, owing to the force of the stream, a new cable cannot be immediately laid, or when there is no ready-made cable available, or when a considerable period must elapse before the new cable can reach the river. To provide for these contingencies attempts have from time to time been made in India to signal across rivers without cables. Three different methods appear to have been discussed and attempted, viz.: 1. Signaling through an imperfectly insulated wire. 2. Signaling through an ordinary bare wire. 3. Signaling without any metallic conductor.

During May, June and July of the year 1888 Mr. Johnston made a long series of trials across the canal and the river Hooghly, and the subsequent measurements and experiments led him to come to the following conclusions, viz.:—That up to 1½ miles it is perfectly easy and practicable to signal through a bare wire under water; that for greater distances, judging from experiments, it is not possible to signal in this manner. In April, 1889, Mr. W. P. Johnston died, and the duties of electrician were entrusted to me. I resolved to change the class of signaling apparatus and to continue the experiment. Discarding continuous steady currents and polarized receiving relays, I adopted Cardew's vibrating sounder. I began from the beginning, and tried to signal across a waterway without a metallic conductor by laying down two earth-plates on each of its opposite banks. Readable signals having been exchanged, the distance separating each pair of plates was varied with the view of ascertaining how close the plates might be brought together, the signals still remaining readable. Readable signals were exchanged when the distance separating was equal to the breadth of the river, reading becoming more difficult as the plates were made to approach each other, and clearer and more distinct as the distance between the plates was made to exceed the breadth of the river. I learnt from these experiments that in order to obtain signals of sufficient distinctness for the practical purpose of transmitting messages, it would be necessary to construct a line on each bank of a river much longer than the breadth of the river; and as the rivers along the coasts in India are extremely wide, I became impressed with the impracticable character of such an undertaking, and decidedto strike out on a new line. This new line was the laying of two bare uninsulated iron wires across the waterway parallel to each other, and separated by a certain distance, the ends on each bank being looped together by means of an insulated conductor. Hence, though much of the circuit was laid under water, it was nevertheless a continuous metallic circuit. Beginning first with a complete square by laying the wires as many yards apart as the river was wide, signals were instantly exchanged that were incomparably louder than those that were exchanged when the same area was bounded by four earth-plates. The length of each of the two wires under water was next gradually increased to 740 yards, and the distance separating them gradually diminished to 35 yards, the strength of the signals diminishing proportionately, and ceasing to be readable when the wires were further prolonged. The conclusion arrived at from these experiments was that for the practical and useful purpose of signaling messages across a broad river in the absence of an insulated cable, a complete metallic circuit was at least desirable. Acting on this conclusion, it was sought to apply it practically, and the following experiment was carried out: At a distance of 15 miles west of Calcutta a cable is laid across the river Hooghly, which at this point is 900 yards wide. The iron guards of this cable were employed to form one of the metallic conductors, and at a distance of 450 yards down stream a single wire, weighing 900 lb. per mile, was laid across the river to form the second metallic conductor, insulated land wires having been run up to loop the two parallel conductors together. The experiment was quite a success, the signals being readable without difficulty.



Elec Engineer, N.Y.

SIGNALING ACROSS RIVERS IN INDIA.

The local line from the Central Office, Calcutta, to Garden Reach is about four miles in length, and at about midway the wire spans a small river. Vibrating sounders having been put in circuit at each end of this line, the wire where it crosses the river was taken down and laid along the bed of the waterway. Signals were loud and clear at both ends. From the success of this experiment it may be inferred that on any ordinary line, should the wire from accidental causes come off the insulator and make earth by touching the bracket, standard or ground, or should the wire break and both ends of it be lying on the ground or in a watercourse, communication could still be maintained by means of the vibrating sounders.

The line wire which connects the town of Chandernagore with Barrackpore is about 10¼ miles long, 900 yards of which consists of a cable laid across the river Hooghly. Vibrating sounders having been joined up in the telegraph offices at Barrackpore and Chandernagore, the insulated conductor of the cable was thrown out of circuit, and the line wire on each side of the river was joined to the iron guards of the cable; thus, for a length of half a mile out of 10¼ miles the conductor was wholly under water, yet it was found quite feasible to transmit messages between the two offices. From the success of this experiment it may be reasonably inferred that in the case of certain cable crossings where the rivers are not too wide, should the copper conductor of the cable make dead earth or become insulated by parting, communication could still be kept up between the two offices on either side.

Each of these three experiments may properly be described as a delicate experiment. With so much of the conductor under water, the quantity of current which reaches the receiving telephone is so infinitesimal that signals could not be successfully transmitted if the vibrator were joined up in the ordinary manner. It is desirable in circumstances similar to these to reduce all the resistance external to the actual connecting lines to as small a quantity as possible, and therefore, when messages are being transmitted, the telephone at the sending end should be removed from the circuit, as also should the vibrator from the receiving end.

To effect this two-fold purpose of a special form of signaling key, designed by the writer, is requisite and should be usen. The action of this key, together with the complete set of connections for a parallel cable crossing is shown in the accompanying diagram. The latter shows the connection for one end of the circuit, that at the other being identical in every respect.

DISTURBANCE OF TELEPHONE SERVICE BY ELECTRIC LIGHTING PLANTS.[1]

A short time since, the city of Bamberg, in Bavaria, erected a plant for lighting a limited portion of the city. The number of lamps used was but 24, these being connected by pairs in series, and fed by a 6-pole dynamo. The conductors of the circuit were separated from one another a distance varying from 15 to 100 metres.

When the above experimental plant was put in operation at the beginning of last December, there was noticed in the 60 telephone wires running across and between the electric light wires, a disturbing, buzzing noise, that interferred with the use of the instruments, and wholly prevented communication with the city of Nuremberg.

The telephone exchange was at a distance of but 130 metres from the dynamo station, and when one telephone after another was connected with wires of the disturbed district, the noise was found to increase with the distance. If two wires, in which the noise was equally loud, were connected together, the disturbance ceased and there was almost perfect quiet in the telephone. On the other hand the noise was greatest when a wire from the disturbed district was connected with one uninfluenced by the light wires. Although in two places the light wires crossed the telephone wires at a distance of two metres, yet the average distance of the two circuits from each other was 110 metres.

In the telephone circuit it was noticed that even when only a single pair of lamps situated at a considerable distance from the station were cut in, the noise in the telephone was quite perceptible.

The cause of this was, of course, the inductive effect of the lighting current due to the peculiar construction of the dynamo producing a variable current.

That the disturbance was principally caused by the direct inductive effect of the light wires, and only to a slight degree by leakage to earth, was shown by constructing a well insulated closed metallic telephone circuit whose return wire was not within the influence of the light wires. Even with this precaution the noise in the telephone was nearly as great as when the return wire was grounded. Further, when both wires of the lamp circuit were attached to the same pole, no disturbance was noticed in the telephones. This fact shows that, if in conformity with the requirement of the Royal Bavarian Telegraph Department, both light wires be placed on the same support, the indicated disturbance to the telephone service would be avoided.

---

[1] Abstract of a paper read before the London Institution of Electrical Engineers, April 10, 1890.

[1] *Elektrotechnische Zeitschrift.*

The electrical engineering concern in Bamberg builds, besides the above named 6-pole dynamo, also 2 and 4-pole machines. In order to ascertain whether, or not, these last named dynamos would show the same inductive effects as the 6-pole machine, the following experiment was made: Connection was made between the city lamp circuit and a 2-pole dynamo in a neighboring factory. When now current was taken at a distantly removed pair of lamps, there was noticeable only a slight noise in the telephone circuit, but which in no wise interfered with the distinctness of conversation. Immediately thereafter currentwas taken from the 6-pole machine giving the current and at the same potential, and the loud noise was at once heard in the telephone.

Finally, in the same factory, by means of a special induction coil, a telephone circuit was subjected to the induction of currents from the several dynamos, and it was found that with the same current, only that from the 6-pole machine produced a buzzing noise in the telephone.

In regard to the insulation of the city light wires it was shown by measurement in damp weather to be only 800 to 2,000 ohms for the insulation resistance of the whole length.

Even this cannot be called favorable, yet the above shows that faulty insulation has no very great effect upon the telephone wires and that the disturbance can not be ascribed to this.

As a result of these experiments the authorities of Bamberg have taken steps to have more appropriate dynamos furnish current for the city lamps.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Kemmler's Respite.—The Edison Phonograph Sale Litigation.—The Electrical Inquests.—Awarding Contracts for Lighting.—Another Lecture by Dr. Wheeler.

One of the most interesting occurrences of the past week was the sudden stay of Kemmler's execution by electricity, through the intervention of Judge Wallace of the United States Circuit Court. Some of the newspapers that had made special and costly preparations have been in a fine state of frenzy since. and their furious attacks on the Westinghouse Company which they regard as the cause of their disappointment border on the farcical, so wild and melodramatic are they A bill is now passing through the Legislature abolishing capital punishment and there are even a few, who, sick and disgusted with the whole business, hope it may speedily be passed. The Westinghouse Company, it may be stated, denies most positively that it has had anything to do with the matter, or knows anything of the agencies at work on the bill abolishing capital punishment.

In the United States Circuit Court on May 2, Judge Wallace entered an order, after hearing the lawyers for both parties, allowing Thomas A. Edison to amend his bill of complaint against Ezra T. Gilliland and J. C. Tomlinson, to recover $175,000, which was a part of the purchase price paid by Jesse Lippincott for the Edison phonograph patents, to Gilliland and Tomlinson as Edison's agents, but, as Edison claims, not accounted for and paid to him by them as should have been done. The Court gives the defendants until June to file their answer. This order will, it is claimed, remove the objections which Judge Wallace recently found to the bill of complaint as originally drawn, and which he dwelt upon in his recent opinions, sustaining the demurrer of the defendants. Mr. Edison's lawyers hope, they say, to have the case finally presented for decision on its merits at the first term of the court after the summer vacation.

An inquest was held last week by Coroner Schultze in the case of Patrick Sullivan, who on December 14, last, was killed by an electric shock in the cellar of the Manhattan Electric Light Company's station, at Eightieth street and Avenue B. He went there to turn on the waste water pipe, and used a portable light. It was shown that the wire of the light was improperly insulated, and for this the jury censured the company, although there does not appear any good reason why the company would be blamed for a thing that the man himself was best able to see and be careful about,

As an offset to this it is encouraging to note that Supt. Pearce, who was indicted for manslaughter, in the case of the death of a clerk named Harris, who was shocked to death while holding a metal case that struck a low hung lamp, has been acquitted. There was no evidence to implicate Pearce, and it is satisfactory to note his acquittal, though of course, it is desirable that lamps should hereafter be so hung that no show case can thus strike them.

The Gas Commission has awarded a number of contracts for street gas lighting, but the controversy with the local electric lighting companies has not yet been settled.

Dr. S. S. Wheeler has again been called upon to lecture upon electricity before a Y. M. C. A. This time it was in Brooklyn, and the large audience was highly appreciative. The lecture ranged over the whole subject in a simple, easy manner, and was most happily and successfully illustrated by experiments and by the operation of ordinary every-day apparatus in such wise that all could "see how the thing worked." The Brooklyn *Citizen* devoted nearly a column to its report of the lecture.

New York, May 2, 1890.

PHILADELPHIA.

Long-Distance Telephone Subways.—An Inspecting Party from Boston.

Director Wagner, as presiding officer of the Board of Highway Supervisors, announced that the American Telegraph and Telephone Co. had distinctly and positively refused to repave over their conduits from the curb line to the railroad tracks on streets occupied by them by permission of Councils. In view of this fact the Director added that he had written to Superintendent Fairbanks, at the company's main office in New York, but without receiving an answer. "I wish to notify you now, gentlemen," said the director to his colleagues, "so that you may know how to deal with this corporation if it should at any time in the future apply for additional privileges. I think though that these people have obtained from us all that is in our power to grant." Chief Walker, of the Electrical Bureau, and Chief Bullock, of Highways, remarked that the trouble arose from some complication between the company and their contractors for street paving.

The Public Building Committee of the Common Council of the city of Boston, consisting of David F. Barry, chairman, and Edward E. Drew, Walter L. Hayes, Perlie A. Dyer, George E. Lovett, and assistant messenger Harry H. Osborne, arrived in this city on April 28. They came here to inspect the electric light plant in operation at the Public Buildings, with a view of adopting the system for the municipal buildings in their own city.

Philadelphia, May 2, 1890.

BOSTON.

Boston Electric Club.—Mr. Mansfield's Paper on Single and Double Trolley Wires.—Business Meeting.—Elevated Railway Legislation.—Permission for Increasing the Stock of the Boston Electric Light Company.—Metallic Circuits and High Tension Currents.—Boston Electric Company to Increase Their Lines.—Suburban Light and Power Company Refused by Board of Aldermen.—West End Street Railway Construction.

Mr. George W. Mansfield, well and favorably known as the engineer of the railway department of the Thomson-Houston Electric Company, read an interesting paper, (which we print more fully elsewhere.) before the members of the Boston Electric Club, on "Single and Double Trolley Systems." Mr. Mansfield is a strong advocate of the single trolley, and maintained from the beginning that it was the only practicable system. He pointed out the many obstacles there were in the way of double trolleys. The paper was listened to with much interest by all, and some discussion followed chiefly on the trouble caused to telephone lines by the induction from electric railway circuits. Mr. W. J. Denver, of the New England Telephone Company, made some interesting remarks relating to induction, and stated that the only cure he knew for induction was a perfect metallic circuit, but that that would require an outlay of a vast amount of money and a greatly increased number of wires; to give some subscribers lying in outlying districts a metallic circuit, would require, not the doubling of the number of wires, but in some cases would require five or seven times as many wires.

The next meeting of the club will be on Monday, when some important business matters will be discussed. Chief among them is a revision of the constitution and by-laws. The club is now entering upon a very successful period, and there are a large number of applications to be balloted for at the meeting on Monday.

The street railway committee has not yet come to any decision or made any special report as to the elevated railway question, and it is generally whispered that there will be lots of fighting before any decision can be arrived at.

The mercantile committee reported a bill to authorize the Boston Electric Light Co. to increase its capital stock to an amount not exceeding $2,000,000, making the entire amount $3,000,000. The new stock may be sold or issued from time to time in accordance with existing laws relating to the increase of capital of manufacturing corporations.

It was reported to the Legislature this week also that it was inexpedient to provide that electric companies shall use metallic return circuits, or to prohibit the use of electric currents of high intensity, The Board of Aldermen refused to grant permission to the Suburban Light and Power Company to erect 861 poles in Roxbury, Dorchester, West Roxbury and South Boston, but granted permission to the Boston Electric Light Company to erect 81 poles in Jamaica Plains and Boston. There will be a hearing on Monday on the petition of the Suburban Light and Power Company for a license to erect eight stationary steam engines of 1,000 aggregate horse power, at Hilton street, near East Chester park.

The West End Street Railway Company have commenced the work of relaying their tracks on Tremont street, starting at Dover street and working out towards Jamaica Plain. Work will soon be commenced on the overhead construction, and the new stations on Albany street and at Cambridge are rapidly progressing. The heavy foundation work at Albany street is now nearly completed, and the brick work is being started. It has been decided not to order any large amount of underground conduit or cable for the present, but several experimental lengths of various manufacture will be laid down at once in the yard, and careful tests made.

BOSTON, May 3, 1890.

CHICAGO.

Electrical Securities.—A New Washburn & Moen Plant.—The Electric Merchandise Company.

THE following prices were bid this week, on electrical stocks, at the Stock Exchange:

Central Union Telephone Co.	61½
Chicago Edison Co.	118

The stock of the Arc Light and Power Company is in strong demand. The company is paying 6 per cent., but it is earning between 10 and 12 per cent. The earnings in December were over 12 per cent. Last month they were about 11 per cent. It has been the policy of the company to put this surplus into extensions, so that the balance-sheet now shows the amount expended for property to be about $1,100,000, although the stock is only $1,000,000. Further additions will have to be made to the plant this summer, and it is probable that an issue of $100,000 of stock will be made at par to present holders. It is also likely that another $100,000 of stock, repesented by the extensions already paid for by surplus earnings, will be issued as a stock dividend. The directors have not formally passed on either of these matters yet, however. There is no disposition to increase the dividend rate, but rather to continue the policy to divert the surplus net earnings to build the extensions that are constantly called for.

The Washburn and Moen Wire Manufacturing Company, of Worcester, Mass., who have very extensive mills in that city, and turn out enormous quantities of wire, barb fencing and other specialties, have selected a large tract of land located in South Chicago, and will erect there an immense plant similar to the one in the East. Wharves, shops and cottages will be erected, and the company will reduce its own iron ores.

The Electric Merchandise Co. at Chicago has been incorporated with a capital stock of $50,000, to manufacture and lease machinery used in the construction of electric railroads. Incorporators, Cyrus Emery, John L. Ludwig and William R. Mason.

CHICAGO, May 3, 1890.

ST. LOUIS.

The Laclede Gas Company's Station.—Utilizing the Water Power of Grand Falls.—Electric Railway Work.

THE new electric station of the Laclede Gas Co. at the corner of Mound and Levee began supplying current for the alleys and city buildings north of Washington avenue on the 1st of April, and the temporary station at the corner of Franklin avenue and Second street has been abandoned and the machinery removed to the new station. This occupies a ground space 100 x 140. The boiler room, 40 x 100 and 30 feet high, contains 3 Heine safety boilers, each of 300 h. p., fitted with Roney automatic stokers, with coal and ash conveyers. There is spare room for five additional boilers. The engine and dynamo room, 100 x 100 feet, two stories in height, contains at present 2 Williams' high speed triple expansion engines, each of 250 h. p.

In the dynamo room—which is the second floor—are placed three 500 30 c. p. Heisler alternators, regulators and exciters, each supplying two circuits. Also two 1,000 16 c. p. and one 650 16 c. p. Brush alternators, exciters and switch-boards. The Heisler system is used for the alley lights, and the Brush system for lighting the city buildings. Four circuits are used in each system. The dynamos are driven direct from the engine shaft by means of the Siemens system of rope transmission, which, together with Hill clutches, was furnished by the Eclipse Wind Engine Co., of Beloit, Wis. The station will be supplied with water by a tunnel driven through solid rock from the engine room to the river, a distance of nearly 500 feet, which is now about ready for the final opening into the river.

The Joplin, Mo., Electric Light plant and the water power of Grand Falls of Shoal Creek have been purchased by an eastern syndicate for $55,000. The power of the falls, which is estimated at 5,000 h. p., is to be utilized by electrical transmission to the various zinc and lead mines in the vicinity. Thomson-Houston electric machinery will be used.

The South St. Louis Railroad have begun on relaying and wiring track, but, as yet, it is not known what system will be used. The Short system—double trolley parallel—after much delay, have received their regulating rheostats, and are now making trials of their motor cars.

ST. LOUIS, April 30, 1890.

PITTSBURGH.

The Michales Mining Machine Company.—Visiting Statesmen.—The Duquesne Traction Co.—New Electric Roads.

THE Michales Mining Machine Co. of this city, has decided to erect a factory at McKeesport, near here, for the purpose of going into the manufacture of these machines. This is the mining machine which has only recently been invented. It has been frequently tested in some of the mines in the Monongahela valley and proved to be thoroughly successful. It is operated with the Tesla alternating current motor of the Westinghouse Electric Co. The Mining Machine company intend to expend $100,000 in the establishment of their plant.

Among the many visitors, who come daily to view the Westinghouse electric works in this city, was not long ago a deputation from the town councils of Connersville, Ind., which is about to establish an electric light plant; and these men came here to examine the Pittsburgh electric light.

The Baltimore and Ohio Railroad Co. is going to light up all the stations between Pittsburgh and McKeesport with electric lights. The company is now putting up a plant at Glenwood, from which these stations will be lighted. The capacity of the plants is 120 arc lights and 500 incandescent.

The Duquesne Traction Company of this city has struck another snag which will involve that corporation in serious litigation. The residents of Hiland avenue, which is a part of the proposed route of the Duquesne road, have filed a bill in equity against the company, and it is hoped that by that means the Traction people will be prevented from laying their tracks on that thoroughfare. Hiland avenue is one of the most fashionable streets in the east end of the city. It has now an asphalt pavement and the residents fear that the road will greatly detract from the value of their property. The suit is based upon the ground that the Duquesne Traction Company, having secured its franchise by a special ordinance has really no right to lay its tracks on any street at all, because such rights can only be granted by a general ordinance.

Mr. J. M. Ferguson, a prominent capitalist of this city, is about to erect a building in Pittsburgh which will contain a very novel scheme for supplying power to the occupants. The building is to be erected to suit light manufacturing purposes. In the basement, a number of dynamos will be placed, which will generate electric power that is to be transmitted to a large number of motors distributed among the various manufacturing plants in the building. The structure will cost about two hundred thousand dollars and it is expected that it will be one of the finest in the city.

The Perry Street Railway Company of Allegheny city, has been chartered in Harrisburg, with a capital stock of $100,000. Another new street railway in Allegheny is the Bellevue Street Railway Company with a capital of $6,000. Both of these roads belong to the Pleasant Valley Electric Railway system.

PITTSBURGH, May 2, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter, previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

LOSS BY HYSTERESIS.—A REPLY TO PROF. THOMSON.

[125.]—In your issue of April 9, in elucidation of certain remarks made by me at one of the meetings of the American Institute of Electrical Engineers, I have made some statements on hysteresis which Prof. Thomson has commented on in connection with his own views on the same subject, as expressed in your issue of April 30.

Prof. Thomson makes a quotation from my letter which shows that he has not properly understood some of my statements, and then goes on to say: "Mr. Tesla seems to forget that *loss*, *waste* and such terms are more scientifically rendered by the words "conversion into heat," * * and, "Now we may consistently amend his quoted statement, etc."

My statements were the outcome and, as it were, a continuation of a practical discussion, and I attached to the words used no philosophical meaning. By energy "wasted" I meant what probably everybody else except Prof. Thomson understood me to mean, namely, energy supplied to the core and not available for a useful purpose. Prof. Thomson states further: "Mr. Tesla seems to forget * * that in nature nothing is wasted or lost, but merely converted." But a little later *he* makes the remark, "The difference then between very soft iron and hard steel so far as *magnetic waste* goes, etc." Prof. Thomson also "seems to forget that *loss*, *waste* and such terms are more scientifically rendered by the words 'conversion into heat' and that in nature nothing is wasted or lost, but merely converted."

I most politely decline the "consistently" amended statement. If Prof. Thomson would have said, that *loss*, *waste* and such terms are more scientifically rendered by the word *conversion*, I would have agreed with him; but I cannot agree as to the expression conversion *into heat*. When on a bright, but cold, winter's day one steps into his office and finds no coal in the stove and switches on the current of a dynamo to a bank of incandescent lamps with the main object of warming up the room, then all the energy that appears as light is *waste;* or, if this distinction which I make is not made by Prof. Thomson, then I will cite the example of a thermo-dynamic engine in which, besides the *loss* in heat there are *losses* in chemical affinities, light, mechanical motion, electricity and magnetism. Everybody must admit that since Prof. Thomson wants to be so eminently scientific it is immaterial for the present consideration whether the *loss* amounts to one or a million units. This being so, I must confess that I fail to see the advantage of substituting for an unscientific but *correct* expression a scientific but *incorrect* one.

After *consistently amending* my statement he says: "Heat action is that swinging back and forth referred to, namely, 'molecular vibration' and if we find that such swinging takes place we must have heat as a result. When the molecules can polarize or turn without being given a swinging movement or vibration, no conversion into heat takes place." If Professor Thomson means to convey the idea that heat action is such a movement of the molecules, which is accompanied by a local displacement of the centres of the molecules, then, considering the existing uncertainty as to the character of *that* movement of the molecules which constitutes heat, he would do a valuable service to science if he would *prove* his view. There is hope that he will do so, for he says: "If we *find* that such movement takes place, etc.," whence I infer that he must have *observed* it. Then again, if we conceive a swinging or vibration without displacement of the centres of the molecules, such as the swinging or vibration of a magnetic needle, for instance—an improbable, but not impossible movement—according to Prof. Thomson, "no conversion into heat," would take place. Yet such movement would be a movement of material particles *in* or *through* matter, and would represent energy. If the movement be arrested in any manner, then the energy of this movement would be transferred or converted into another kind of movement or form of energy; and since Prof. Thomson says that it would not appear as heat, then in the sentence, "no conversion into heat takes place," the word "heat" ought to have been emphasized.

As to the statement, "When the molecules can polarize without being given a swinging movement or vibration," I must admit that with my weak intellectual powers I cannot perceive how in the world they *can* polarize without a swinging movement or vibration; but I can easily see that they can *be polarized* (for any length of time) without a swinging movement or vibration. However, Prof. Thomson may be able to explain.

Prof. Thomson further says: "Heat action is that swinging back and forth referred to, etc." The swinging back and forth referred to by me is that *assumed* angular and local displacement of the molecules which is directly produced by the reversals of the current in the coil energizing the core, and which may be effected, say, 250 times a second. Since, according to Prof. Thomson himself, not *any* movement but a *particular* movement or mode of motion of the molecules constitutes heat, then, instead of saying, "heat action is that swinging back and forth referred to, etc.," would it not be more correct to say that the energy of these comparatively few "back and forth" movements of the molecules is converted into heat by increasing the amplitude or number per unit of time, or both, of the original vibrations of the molecules?

After stating that, "when the molecules can polarize or turn without being given a swinging movement or vibration, no conversion into heat takes place," Prof. Thomson says: "In like manner, bending a bar of tempered steel back and forth within limits, is mechanically efficient, because *very little conversion of motion into heat takes place*, and this is a result of the *relative positions of the molecules being preserved*, etc." Then, after all, there is *some*, however small, conversion into heat, though, according to Prof. Thomson, there ought not to be *any*, since no swinging movement or vibration back and forth is imparted to the molecules, their relative positions being preserved.

Then comes the statement: "The difference between very soft iron and hard steel, so far as *magnetic waste* goes, is, apparently, that in the soft iron there is less disturbance of position of the molecules during magnetization and reversal than in steel, assuming the degree of magnetization or polarization to be equal in each." The italics are mine. While this *ex professo* assumption cannot be contradicted, yet it has very little in its favor, and is not in harmony with the views of the most competent scientists, who prefer to assume that the molecules of steel move with greater stiffness, or, in other words, that, for *the same disturbance of position*, more energy is required in hard steel. Maxwell has shown, theoretically, that in removing a permanently magnetized body to infinity from another magnet, the work done is twice as great as when removing to infinity the same body magnetized inductively to the same degree. Since a weakening and strengthening of the inducing magnet is equivalent to its removal, or approach, respectively, we can conclude from this consideration alone that the dissipation into heat will be the greater, the longer the molecules are capable of *retaining* the induced *magnetism*, and that under otherwise equal conditions the probable theoretical limit in hard steel will be reached when the dissipation is twice as great as that in wrought iron. Now this quality of retaining the induced magnetism *is* commonly attributed to the steel molecules. A graphical representation shows at a glance the importance of this lagging of induced magnetism, and makes it appear more probable that this quality of *retaining*, rather than the greater displacement of the molecules, is the cause of the greater dissipation in hard steel.

Prof. Thomson further states: "The *waste* or conversion due to electrical resistance is of the same nature." I hardly need point out the fallacy of this statement. The waste or conversion due to magnetic action is always proportionate to the number of the molecules of the magnetized body; the *waste* or conversion due to electrical resistance is not always proportionate to the number of the molecules of the conductor. Ether is an excellent conductor of magnetism, but may be a conductor, or perfect non-conductor, for an electric current, and the conditions determining this are unknown to us. From this alone it should be concluded that both conversions cannot be of the same nature. But an example will make it clear. Suppose we partly exhaust the air in a Geissler tube and pass an electric current through the air in the tube; then a certain resistance will be offered to the passage of the current and a certain amount of energy will be converted. Now, we may exhaust more air and at a certain point there will be an increase of resisttance. So we may go on until we reach any desired degree of rarefaction. The resistance and consequently the *waste* due to the same will continue to increase, yet the disturbance so far as the air molecules are concerned—since their number will be enormously reduced—will be continually diminishing in amount. Assume the vacuum to be reached, then the resistance may be assumed infinite; there would then be, in the sense of the statements of Prof. Thomson, *no* disturbance, namely no disturbance of the air molecules, since there are *none* in the tube; yet the *waste* may be anything.

On the other hand we know from theoretical considerations and practical results that the "magnetic waste," to quote Prof. Thomson, is, under otherwise equal conditions, strictly proportionate to the number of molecules of the magnetized body.

Then comes the statement: "Whenever the ether strain can be transmitted from molecule to molecule of the conductor without much disturbance of their positions or without causing a swinging out of position back and forth, the conductivity is great and the reverse is true for bad conductors." Since the conductivity is measured according to a common standard this statement must stand the test of relativity and then it seems to me to be so evidently erroneous that it hardly need be contradicted. If we pass a current through a carbon filament and bring it to incandescence we cause a certain disturbance of the molecules. If we pass *more* current we produce a *greater* disturbance in the filament; nevertheless the conductivity is *greater* in the latter case. Prof. Thomson "seems to forget" that the conductivity of a body is determined by two things, namely, the conductivity of the molecules *per se* and the conductivity of the intermolecular ether. Hence, in passing a current through a conductor we produce two disturbances—that of the molecules and that of the ether in the space between them; and all who understand the problem of efficient light conversion are trying hard to confine most of the disturbance which may be caused by whatever *is* electric current, or moving electric charge, to the ether. From this it is evident that in some cases we may produce a *greater* disturbance of the molecules of the conductor and yet have *greater* conductivity because of the relatively smaller disturbance of the ether, since the conductivity of the conductor, as a whole, is a function of both the conductivities of the molecules and of the ether. The more the ether disturbance is made preponderating, the more efficient will be the light conversion. These facts have evidently escaped the notice of Prof. Thomson. This statement, so far as it applies to bad conductors, is likewise contradicted by the behavior of a great number of bad conductors which become good conductors under certain conditions. If, in the previous statement, Prof. Thomson means not the integral sum of the disturbance of position of the molecules, but the amplitude of the disturbance, then I only need to cite the example of an incandescent metallic conductor to disprove the general truth of his statement.

Then again Prof. Thomson says : "There is then to my mind no more difficulty in understanding (conceiving?) that a conversion into heat may be produced magnetically than electrically, or mechanically." For one so particular in the use of terms as Prof. Thomson, the expression that a conversion into heat may be *produced*, is not a happy one. Conversion into heat may be *effected*, not *produced*.

What I have said above will also have a bearing on a later remark of Prof. Thomson : "It is in my view more legitimate to attribute the heating effects of Foucault currents and other currents to a general molecular friction or hysteresis of conduction, if we may use such a term, than to assume the production of molecular currents in the heating or conversion of magnetic hysteresis,"—in which he treats the question of hysteresis *homeopathically*, as it were. There occur in Prof. Thomson's lettter expressions like "transmission of ether strains," "reducible to a single effect," etc., and some other contradictions which I have no time to comment on, but which will be observed by the careful reader.

Prof. Thomson concludes with the truly philosophical statement that we neither need to assume, nor can we deny, the formation of molecular currents,—and the reader is no wiser than before.

Nothing, however ably said or written, is unapproachable to criticism. A slip of the tongue in an *extempore* discussion, or a slip of the pen in a hurried letter, can easily occur; but a fair minded critic will make allowance for this and will not fall into the faults of pedantry and cavilling. But if one, without cause, makes himself guilty of these faults he ought to be dealt with in a like manner. If one is exacting he ought to take care to be exact himself. The error of one who makes an incorrect statement is not nearly as great as that of him who attempts to point out the error, and is in error himself. But, above all, one so liable himself to mistake ought not to assume the role of tutorship.

NIKOLA TESLA.

NEW YORK CITY.

WORDS OF GREETING.

WITH its 100th number, issued on the 2d instant, THE ELECTRICAL ENGINEER of New York, became a weekly publication. The change, we are informed, was made necessary by the remarkable recent development of the electrical field, in which discoveries and inventions have multiplied so rapidly that a monthly digest and record, according to the original plan of the publishers, has become inadequate and at the same time unwieldy. Beginning with the new series, THE ELECTRICAL ENGINEER will be published by a corporation organized under that name, while the editorial department will be in charge of T. Commerford Martin and Joseph Wetzler. We regard our contemporary as one of the most admirable among American class-journals, and trust that it may long live to review for its readers the world's progress in theoretical and applied electricity.—*Roller Mill.*

AMERICAN electrical journalism promises some new and exciting developments in the near future. We have already announced that the late editors of the *Electrical World*, Mr. T. C. Martin and Mr. Joseph Wetzler, have somewhat abruptly left the paper they have been so long connected with, and have taken the position together as editors of our namesake, the New York ELECTRICAL ENGINEER. This week the larger paper briefly announces its change of editorship under the heading of "another step forward," so that although no details or explanation of the rupture have been divulged, it seems to be evident that somewhat strained relations have preceded the event. Other changes are also reported, Messrs. Colvin and Shaw having also left their positions and joined the retiring editors. The engagement is announced as editor-in-chief by the *Electrical World* of Dr. Louis Bell, a well-known professor of high reputation in electrical physics. Meanwhile the New York ELECTRICAL ENGINEER, hitherto a monthly certainly with the highest scientific flavor, but naturally less go ahead than its contemporaries, is to be transformed into a weekly, and it is to be expected that under the spirited direction of the new editors a keen rivalry will be established, in which, taking into consideration the immense scope of the vast continent over whose electrical progress they will keep watch, we wish them both heartily progress and success.—*London Electrical Engineer.*

THE HALIFAX AND BERMUDA CABLE.

Mr. Joseph Rippon, general manager of the Halifax and Bermuda Cable Co., has arrived at Bermuda, and has selected a landing place for the company's cable about one mile from Hamilton, Bermuda, at which place the office will be located. The steamer "Westmeath," chartered to lay the cable, leaves London in about 10 days, and it is expected that communication will be established between Halifax and Bermuda by the middle of June.

DEPTFORD.[1]

Further reports of the failure, past, present, or future, of the Deptford station continue to be rumored, and, we suppose, will until the station is entirely opened. As a matter of fact, the Deptford station is working now, and has been working practically every day since November last, supplying current for the Grosvenor circuit—at half pressure, but usually full current—Deptford working as a reserve to the Grosvenor plant. A second engine is now erected, and sundry small improvements are being introduced into the second dynamo before starting. The reports of the failure of the Ferranti mains are devoid of any foundation. Recently a length of main, consisting of some 30 or 40 lengths, and extending round the Deptford station, was tested with transformers up to 18,900 volts without failure. The mains are considered quite satisfactory, and tons of the lengths are being manufactured. Some miles are already laid along the route in different parts. Although more time has been taken than has been expected, yet it is sufficiently noteworthy that, with the exception of enclosing the mains to satisfy certain authorities, the work at Deptford has all been carried out as originally proposed and determined, and the engineers avow themselves thoroughly satisfied with the result both of the dynamos and the mains.

A DENIAL FROM MR. WESTINGHOUSE.

The following letter from Mr. George Westinghouse appeared in all the Sunday papers :

"The recent articles and editorials in the daily papers connecting the Westinghouse Electric Company with the efforts of Mr. Roger Sherman in the Kemmler case, and with the passage of the Curtis bill for the abolition of capital punishment, have caused a number of my personal friends to insist that it is my duty to make a public denial of these statements. I therefore desire to say in the most emphatic manner possible that neither I, nor the Westinghouse Electric Company, nor any person associated with me, has any connection, direct or indirect, with the habeas corpus proceedings instituted by Mr. Sherman in the Kemmler case, or with the effort to abolish capital punishment in this State by legislative enactment. I make this denial without any reservation of any character.

"If there are any electrical interests behind these movements it is not the Westinghouse Electric Company, but it is more likely to be those electrical companies who, in the hope of injuring the business of a rival, caused electric lighting dynamos of a particular manufacture to be adopted by the State for execution purposes, and now find that the agitation which they have instituted and kept alive is reacting against themselves."

INFLUENCE OF MAGNETIZATION ON ELECTRICAL CONDUCTIVITY.

The curious influence of magnetization on the electrical conductively of iron, nickel, and cobalt, has recently formed the subject of a research by M. Goldhammer. Plates of the different magnetic metals were placed parallel or perpendicular to the lines of force produced by a large electro magnet, and the resistance of them was measured by a Wheatstone bridge. For bismuth the percentage variation was found to be proportional to the square of the magnetizing force, and also to the square of the magnetization; since, for this metal, there is a constant ratio between the two. The greatest variation took place perpendicular to the lines. For nickel and cobalt the resistance increases in the direction of the lines, and decreases in the perpendicular direction, the variation being independent of the sign of H, the magnetizing force. The precentage variation tends rapidly to a maximum as H increases, and attains it sooner for cobalt than for nickel; and since the curve connecting the two is very much like the curve connecting H with the intensity of magnetization, the author assumes that the variation, as in the case of bismuth, is proportional to the sqare of the magnetization. M. Goldhammer concludes from his experiments, and from some due to M. Du Bois, that in a magnetic field the physical properties of metals undergo modifications dependent on the directions of the lines of force. If these alterations are reversed with the reversal of the lines they vary directly as the magnetic intensity, while, if they are unchanged by the reversal, they are proportional to the square of the magnetic intensity.

ELECTRIC TRAM-CARS IN BERLIN.

Negotiations are proceeding between the General Electric Co., of Berlin, and the principal local tram-way company, with a view to the introduction of electric traction on the latter's system. The first line to be worked is the portion called Friedrichstrasse-Kreuzberg, and operations will be commenced as soon as the Berlin Municipality has given its consent to the employment of electric tram-cars. Only half the number of cars on the line in question will be fitted electrically. The reason for this is because the cars are small, and two cars will be coupled together.

LEGAL NOTES.

MUNICIPAL LIGHTING.

STATE OF OHIO EX. REL. HAMILTON GAS AND COKE CO. VS. CITY OF HAMILTON.

The case of the State ex. rel. Hamilton Gas and Coke Co. vs. City of Hamilton, recently decided by the Supreme Court of Ohio, is deserving of the attention of all those who are interested in municipal franchises.

The facts in the case, as stated in the majority opinion of the Court, are as follows:

The Hamilton Gas Light and Coke Company was organized and duly incorporated in the year 1855, under the general incorporation act of May 1, 1852, for the purpose of supplying gas for the lighting of the streets and public and private buildings in the city of Hamilton, Ohio. At the time of its organization, by virtue of the provisions of an ordinance of the city of Hamilton passed in the year 1855, there was granted to the company, and it thereafter had, the use of the streets of the city, for the purpose of laying gas-pipes and mains, and supplying gas to the city and its inhabitants, for the period of 20 years, to wit, until the year 1875. Since the year 1875 the city has used the gas of the company only in accordance with the terms of various contracts entered into between the city and the company, from time to time, the last of which contracts expired January 1, 1889; and since the last-named date there has been no contract existing between the parties; the city has declined to use the company's gas, and has provided other means for lighting its streets. For the purpose of manufacturing gas, the company erected gas-works, and laid gas-pipes and mains, to the probable extent of 30 miles, throughout the city, for the furnishing of gas for public and private consumption. It is conceded by the defendant that the company has complied with all the provisions of the law of Ohio relating to gas companies, and with all the ordinances in that behalf of the city of Hamilton, and is entitled to all the rights, privileges, and immunities secured to such companies by the laws of the State. The city of Hamilton is a municipal corporation organized under the laws of the State of Ohio, and had, at the last federal census, a population of 12,122, and a corporate area of about three square miles. On the 4th day of September, 1888, the city, by its council, on the petition of a large number of its inhabitants, duly passed an ordinance providing for the submission to the qualified voters of the question of issuing the city's bonds to the amount of $150,000, for the purpose of gas-works to be erected by the city. Legal notice having been given, the question was voted upon by the electors at the general election held on the 6th day of November, 1888, and resulted in 2,412 votes being cast for the issue of bonds, and 59 votes against such issue. Upon that decision of the electors, the city council, on the 20th day of November, 1888, adopted a resolution that it was deemed expedient, and for the public good to erect gas-works at the expense of the corporation. On the 18th of December, 1888, an ordinance was passed by the council providing for the issue of bonds, for the purpose of erecting such works by the city, to the extent of $150,000. The entire issue was sold for more than the par value thereof, and the proceeds of the sale were turned over to the city treasurer for the erection and completion of the proposed works. On the 7th day of May, 1889, trustees of the gas-works were appointed by the city council, who duly qualified, organized their board, and proceeded to the erection of the works, in accordance with the decision of the citizens and taxpayers of the city of Hamilton. The board of trustees so appointed purchased land for the erection thereon of the proposed gas-works, agreed upon plans and details for the construction of such works, entered into contracts for the furnishing of material and the performance of labor, paid large sums of money upon contracts for material furnished and labor performed, and, in the execution of contracts, gas-pipes were extensively laid in the streets of the city. The defendant alleges that the gas-works are being built by the city for the purpose of furnishing the public lighting to the city, and that no action has been taken towards furnishing gas for private consumption; but the defendant cannot say what action, if any, the city will in the future take towards furnishing gas for private consumption.

* * * * * * * *

Under these facts, and under the Ohio statutes, a majority of the Supreme Court found against the Gas Company, and decided practically that a gas company operating under a municipal franchise has no legal protection against competition by the municipality itself, although such competition should mean confiscation of the property of such gas company.

There was, however, a vigorous dissenting opinion by Judge Spear, some extracts from which follow:

This company was organized in 1855, under the act of May 1, 1852, "to create and regulate gas-light and water companies." Its purpose was to manufacture gas and furnish it for lighting the streets and public and private buildings in the city of Hamilton. This was a public purpose. Its accomplishment would benefit the city by enabling it to more effectually protect persons and property therein. In accepting the provisions of the laws then in force, the company, in consideration of the privilege granted, undertook to supply a public want. This duty it cannot avoid or shirk. Neglect of it, as we will presently see, would subject it to severe loss and possible deprivation of corporate existence. To avail itself of the rights and privileges conferred, and to enable it to perform the duty imposed, the company, under the authority and direction of the city of Hamilton, expended large sums of money in the construction of works and the laying of mains in the streets of the city, and the furnishing of facilities for the supply of gas to the city and its people, taking upon itself whatever risk of return upon the capital thus invested there might be in the venture. It undertook this work and assumed this risk in view of the law regarding gas companies, and the power of municipal corporations over them. The act referred to authorized the incorporation of such companies for the "purpose of supplying gas to light the streets and public and private buildings of the city," etc., the purpose to be specified in the certificate of incorporation, and, when incorporated, the companies were authorized to carry on the operations named in the certificate, without limitation as to time. They were to "have full power to manufacture and sell gas, and furnish such quantities of gas as may be required in the city * * * for public or private buildings, or for other purposes," and, in order to accomplish this, were given power to lay conductors for conducting gas through the streets, etc., with the consent of the municipal authorities. Amendments to the act gave to municipal corporations the power to regulate the price at which gas companies should furnish gas to the city and to private consumers, to fix the price for rent of meters, and to require them to lay pipes and light such streets as the council might direct. On failure to extend pipes as directed, the city could erect works and lay pipes for the supply of such streets and other streets not lighted. A neglect of the company to furnish gas to the citizens or other consumers of gas, in accordance with prices fixed by the council, would forfeit all its rights, and the city could then erect, or authorize any person to erect, works, and supply gas to the city and private consumers. Such, in brief, were the provisions of law on the subject at the time of the incorporation of this company. Under this law, so long as a company complied with every lawful requirement to the public and to private consumers, the public object of the statute was accomplished, and, if the construction I contend for be correct, the right of the company to furnish gas to the city and to private consumers therein remained unimpaired, and the city had no power to interfere with the company's chartered rights by entering into competition with the company while carrying out the purpose of its organization. It is not pretended that this company has, in any respect, failed in the performance of any lawful requirement.

* * * * * * * *

In effect the statute gave to this company the exclusive right, so long as it complied with every requirement of law, to supply gas to the city of Hamilton and its inhabitants. This right was upon condition of performance of the required service by the company, an object beneficial to the community, and was a grant of a franchise vested in the state. Based, as it was, upon abundant consideration, and there being competent parties and a lawful subject-matter, the transaction was, in all essential particulars, a contract between the state and the company; and if, as I claim, and think can be maintained, there was granted an exclusive right, any taking back by the state in the manner proposed would be a violation of that contract, and would result in the taking of private property without compensation. The extent to which such contract may be changed, under the constitutional power to alter or repeal, will be considered further on. By the act referred to the general assembly did not part with the police power and duty of protecting the public health, the public morals, and the public safety, and hence such contract was not in excess of the power of that body.

* * * * * * * *

The construction of the statute claimed by the city is not reasonable. It shocks the moral sense. To admit that the legislature, after having, by laws enacted prior to the organization of this company, held out to gas companies an inducement to invest large amounts of money in works and pipes for the purpose of establishing their business of furnishing "such quantities of gas as may be required," would, when the expenditure had been made on the faith of the power granted, by an amendment, give to municipal corporations the power to embark in the same business, to supply the same want, and thus place the property of gas companies wholly within the control of municipalities, acting on the caprice of city councils, or the impulsive vote of the people, is to presume a lack of good faith in matters of state which would be dishonorable between individuals. A statute ought not to receive a construction warranting such a conclusion, unless its terms are so direct and unambiguous as to admit of no other construction; and if to give the construction contended for would result in an interference with vested private rights, and cause the state to legislate back to itself the franchises, rights, and privileges which it had created, and thus destroy the corporeal property of the corporation without compensation, then such construction is not permissible, because it drives us to the conclusion that the statute is unconstitutional. Sinking Fund Cases, 99 U. S. 718. "A statute should not receive a construction which makes it conflict with the constitution, if a different interpretation is practicable." Burt *v.* Battle, 31 Ohio St. 116.

It seems to be feared that this gas company cannot be accorded the right given it by the statute under which it was organized to furnish the gas that may be required in the city of Hamilton, because to do so would be a violation of the clause of the constitution (section 2, art. 1) which forbids the legislature to grant special privileges that may not be altered, revoked or repealed, and because there would thus be created a monopoly. If this is seriously urged, the answer to it is that no special privilege or immunity is created, because all citizens in Ohio had equal right, under the law, to organize a corporation for the purpose of doing what, in the nature of things, only one organization could do, namely, supply the need of the city of Hamilton for gas; and no monopoly, in any objectionable sense, was or could be created, because the company was absolutely within the control of the city, as to the price of its commodity, and, in all essential particulars, in the conduct of its business with the public. It is not wise to be too easily disturbed by the cry of "special privileges" and "monopoly." Those terms became odious from the fact that in England, by law or by royal prerogative, letters patent to particular individuals were granted to conduct certain lines of business, or trade in certain commodities, to the exclusion of all others, which resulted in the restriction of production, the impairment of the quality of the article produced, the enhancement of prices, and the enrichment of the few and the impoverishment of the many, and it was to forever prevent such enactments that the section of the constitution referred to was ordained. But no such result, in either aspect, could possibly ensue in the case we are considering, and hence no valid objection on the ground urged exists. On the other hand the business of this company was a business of a public character, at least so far as supplying the needs of the city was concerned. It was a want which the state might directly, or through a proper agency, supply by contract. In principle the case is not essentially different from that where the state lets to a bidder, where but one appears, the right to erect some public work. The advantage, if any results, may extend over a longer time, and it may not; but, however that may be, all citizens having the means, have an equal right and opportunity to avail themselves of the advantage. In this case the state held out the inducement to all citizens to organize for the purpose of supplying a public want of municipal communities. The incorporators of the Hamilton Gas Light Company accepted the state's proposition as regards the city of Hamilton. No other citizens did accept it. The company then went forward, and, in all respects, performed the duty, complied with the law as it then was, and with all amendments as to its proper regulation which have since been enacted. With what grace can the state now say to it, "You must withdraw, and leave to another agency the performance of the duty we intrusted to you, and lose the value of the property you have acquired in performing that duty,—property which, from its nature, can neither be removed nor profitably applied to any other purpose?" And from a moral standpoint as well might the state, after it had contracted with a citizen to erect a public building, and after he had procured his material, constructed his machinery, and employed his labor, ignore its contract, purchase its own material, construct its own machinery, and proceed with the public work.

* * * * * * * * * * *

Nor would a judgment of ouster work injustice to the city, for, before the expenditure of any money or the incurring of any obligation on the part of the city, it was duly notified of the claims of the company, and that legal action would be taken to enforce them. It is not assumed that there is any vested right in the gas company to light the city of Hamilton. It was to furnish what gas might be required. So that, when gas is not longer required, the right ceases. The city may return to oil or gasoline, or adopt some newer agency, as electricity, and the people may refuse to burn gas; and of this the gas company cannot complain, because its rights are not invaded. That a time might come when gas would not be required was one of the risks the company assumed. But so long as the streets, public grounds and buildings of the city are to be lighted with gas the right of this gas company to do that lighting, it seems to me, cannot be lawfully denied. Of course it is subject to the control of the city in all the particulars specified in the statute under which it was organized, and in later statutes relating to regulation. Under such authority the power of the city to regulate is ample. This regulation, however, is confined to the carrying out of the purpose for which the company was organized. While it may regulate, it may not destroy. The contention of the city shocks the sentiment of common justice. It is opposed to the general policy of the national government, as shown by the decisions of its highest court, and the action of its executive officers, and to that of our own state. An instance is referred to by counsel. Turnpike companies and plank-road companies were authorized by statute, and many toll-roads were built in various parts of the state, with right to take toll from all travelers. When the state sought to resume the power granted, provision was made by statute (section 8,036, Rev. St.) by which the companies should be paid for their property, and commissioners of counties, where these roads were located, were authorized and required to purchase the property of such companies within the county, and to issue bonds for the payment of same. Under this act, as is stated, Butler county alone has paid over $40,000. In its action in this matter the state has been governed by the plainest principle of justice and fair dealing. The same principle applied to the city of Hamilton and the gas company would require that, if the city desires to engage in the gas business, it should undertake to avail itself of the power given in section 2,486, and endeavor to buy the works already in operation there."

ELECTRIC RAILWAY EARTH RETURN CIRCUIT.

THE EAST TENNESSEE TELEPHONE CO. VS. THE KNOXVILLE STREET RAILROAD CO.

HENRY R. GIBSON, *Chancellor.*

This is a suit brought by the telephone company to enjoin the railroad company from using the earth as a return electric circuit, and from interfering with the electrical condition of the air, to its injury.

The telephone company claims:

(1) That it has a grant from the city to erect poles and string wires in, over and along all the public streets and alleys of Knoxville;

(2) That it has such posts and wires, and is doing a telephone business;

(3) That the railroad company is about to use electricity as a motor, with the earth for a return circuit;

(4) That the telephone company is now using the earth for its return circuit;

(5) That both companies cannot so use the earth at the same time, as the telephone current is too delicate to contend with the railroad current;

(6) That the railroad company's wires are also liable so to affect the electricity in the telephone wires, or are liable so to charge the air with its electricity, as to interfere with the very delicate electrical currents used by the telephone company;

(7) And that the telephone company has a "vested right" to the "exclusive use" of the earth and the air as against every person using the same for electrical purposes to the detriment of its telephones.

For these reasons the telephone company has obtained a temporary injunction against the railroad company inhibiting the latter from using the single trolley system or any other system that uses the earth for a return circuit.

To this bill the railroad company has put in a sworn answer, setting up, among other defenses, the following:

(1) The ordinance under which the telephone company claims its rights does not vest in it any such rights as it claims.

(2) That what rights the ordinance does give are not the property of the telephone company.

(3) That the railroad company's electrical appliances will not injure the telephones.

(4) And that if they should, the injury can cheaply be remedied.

On this answer, the defendant moves the Court to dissolve the injunction.

On the hearing of this motion, the affidavits of many electrical experts have been read, much electrical literature has been offered, not a few judicial opinions have been cited, and most able and elaborate arguments have been made. The whole subject of electricity has been brought before the Court, including a miniature telephone plant and a miniature electric car and electric railroad, so that Menlo Park itself seemed, in miniature, before the Court. The main questions for determination presented by the pleadings are: 1st, were such rights as the telephone company claims conferred upon it by the city of Knoxville; 2d, if so, are they exclusive and monopolistic in their nature?

On examining the bill I find that the telephone company avers that on October 22, 1880, it was "granted the right and privilege to erect its poles in, over and along the public streets, alleys, lands, roads and public squares of the city, to string its wires thereon, and to use and operate the same for the purposes of telephonic and telegraphic communication;" and that relying on said franchise it has constructed a telephonic plant and is now operating the same.

This averment is the foundation of the telephone company's right and claim to relief; and the truth of this averment is doubly denied by the railroad company, which says that no such franchise was granted, and that what was granted was granted to the telephone *exchange* and not the telephone *company*. On examining the ordinance of the city I find it reads as follows: "Be it ordained, etc., that the privilege of erecting poles on the public streets and alleys of Knoxville be granted to the East Tennessee Telephone Exchange, and this privilege of erecting posts shall be confined to telephone exchange purposes exclusively. That the posts erected shall in no way interfere with the public travel along the streets, sidewalks and public alleys of the city. That nice posts, straight and smooth, be required, and that the same be in line with the outside edge of the curbing."

To an impartial mind this ordinance does not seem to "grant the right and privilege to erect poles in, over and along the public streets, alleys, lands, roads and public squares of the city." The ordinance confines the location of the poles to the streets and alleys, and says nothing whatever about "lands, roads and public squares;" nor does it say the poles may be erected "in, over and along the public streets, etc.;" it says "on" the streets and "in line with the outside edge of the curbing." Neither does the ordinance say a word about any right "to string wires" on said poles, or about "using and operating the same for the purposes of telephonic and telegraphic communication."

I mention these matters for the purpose of ascertaining what rights were granted by said ordinance—to measure their comprehensiveness. The bill claims practically unlimited rights to erect poles, string wires, and "use and operate the same" "in, over and along" all the "public streets, alleys, lands, roads and public squares" in the city; whereas, the ordinance merely gives the "Exchange," not the company, the "privilege of erecting poles on the public streets and alleys, ... this privilege to be confined to the telephone exchange purposes exclusively."

It must be remembered that the telephone company does not claim any particular right of way, or strip or piece of ground, or any particular streets or alleys, within the limits of Knoxville, for its earth circuit, but it claims the whole of the surface of the earth, and all that is beneath the surface of the earth, within the corporate limits, as its exclusive property for all the purposes of an earth circuit.

Now, if at the time this ordinance was passed, any one had suggested that this limited privilege of "erecting poles" gave the Telephone Exchange a right to use all the ground on which the city stood, public and private, as an easement to be used in place of wires, to complete its electrical circuit, he would, no doubt, have been regarded as a wilful distorter of language. But if, in addition, he had claimed that this meagre privilege of "erecting poles" not only gave the Telephone Exchange a right to use all the ground, public and private, within the corporate limits as its own, but the right to use it to the exclusion of all other electric companies from now to the ending of the world, he would have been regarded as a wicked exaggerator, if not a deliberate falsifier. And yet this is exactly what the telephone company claims in its bill.

I am unable so to construe this scant "*privilege* of erecting poles" as to make it "grant the right" to the exclusive use of every inch of ground within the corporate limits, for all the purposes of an earth circuit for electricity. Such a grant could never have been in the minds of the Mayor and Aldermen; and I am unable to find these exclusive rights and monopolistic powers condensed in five such harmless words as "the privilege of erecting poles."

The telephone company, however, does not content itself with literally claiming the exclusive use of the whole of the earth on which Knoxville is built for its return electrical currents, but it claims a monopoly of the whole air also, and insists that no other electrical company can string its wires in the near neighborhood of the telephone wires. And thus the simple privilege of "erecting poles" on the side of the streets of Knoxville is magnified into a grant of the exclusive right to all the earth and all the air within the corporate limits of Knoxville, for all electrical purposes, except telegraphing.

But it may be urged that the ordinance says that "this privilege of erecting poles shall be confined to telephone exchange purposes exclusively." So it does; but will it be contended that these words, which are rather words of limitation than of extension, give the telephone company the exclusive right to use every inch of Knoxville's ground and a superior right to all its air, as its private property for electrical purposes?

And thus it is, this once humble telephone company, that was given the bare privilege of "erecting poles" on the edge of the curbing, now comes forward, and, by virtue of those two talismanic words, claims the right to make the electric light companies, the electric railroad companies, and all other electric companies, for all time to come, keep their wires from communicating with any part of the ground on which the city stands or else pay it for the privilege of so doing. In a word, it claims a perpetual monopoly of the earth upon which the city is built for all the uses of an electrical circuit; and also claims a superior right to the air itself, for electrical purposes.

Ordinarily a person's strength consists of his physical power, but the telephone company's strength is sought to be derived from its weakness; it says that its electrical current is so weak that all strong currents greatly affect and impair its usefulness, and that, as a consequence, no company using a strong current can lawfully use the earth for a return circuit without its leave. If this contention be correct, then no electric company can ever use the underground on which Knoxville is built without the consent of the telephone company. It makes no difference what grand discoveries and inventions in the use of electricity may be made. Coal, wood, gas, steam and animal power may all be superseded by electrical devices, machines may be invented to heat and light all of our homes, do all of our cooking, propel all of our vehicles and machinery, and all or a large part of this electricity may be drawn from the earth, or it may be drawn from the air, and yet Knoxville and her people are to be denied all of these wonderful benefits for all the ages to come, if they, either through the earth or through the air, in any way cripple or injure the feeble current of the telephone company, unless the telephone company gives or sells its consent.

The streets of Knoxville are held in trust by the city for the benefit of the people, to the end that the people may have the right to walk and ride and transport goods and animals, and propel vehicles over and along them. And the city has no right to allow the streets to be used for any purpose inconsistent with these rights of travel and transportation. Telephone poles have no connection with travel or transportation, and have no just rights on our streets, and are, at best, mere tenants at will. These doctrines were distinctly recognized by the city when it granted this privilege of "erecting poles," the ordinance emphatically providing that "the posts erected shall in no way interfere with the public travel." It may be said the trouble grows not out of the "posts" but out of the "wires." To this it is answered that the word "wire" is not in the ordinance, and all the right the telephone company has to use wires is as an incident to the post, and what the ordinance means is that neither the posts nor the wires on them shall, in any way, interfere with the public travel. In other words, this privilege of "erecting poles" or posts, is to be, in every respect, subordinate to the use of the streets, for public travel. If this be the meaning of the ordinance, then the city has the right to allow electricity to be used as a motor for the propulsion of street cars, and if the telephone poles or wires "interfere with the public travel" on these electric cars, the city has a right to have them removed. And, on this ground, also, it will thus be seen that instead of the telephone company having exclusive and monopolistic rights both to the earth and to the air for electrical purposes, it is a mere humble occupant of the streets, by permission of the city, and liable to be declared a nuisance whenever its poles or wires interfere with the public travel.

Fast, indeed, must our rights be slipping from us, and most insecure, indeed, must be their moorings, when such claims as these are countenanced by the courts. I have, heretofore, declared in a suit between the defendant and the city, that our streets are public property under the trusteeship of the Mayor and Aldermen, and very slowly and very reluctantly will I ever decide that any of the property of the people has become the fee of any one person, whether such person be a Kentucky corporation or one native born.

I might go further and show that there is no evidence or allegation that the E. T. Telephone Company, a corporation under the laws of Kentucky, is the E. T. Telephone Exchange that acquired this privilege of "erecting poles." The answer denies their identity, and the ordinance supports the answer. In the light of the present claims of this telephone company to the benefit of this ordinance, and to the monopoly of ground on which the city stands, for all the purposes of an earth circuit, I can only say that if such was its object when it secured the apparently humble privilege of "erecting poles," it was seeking to perpetrate a fraud upon the city of Knoxville, whose Mayor and Aldermen could not have supposed that they were selling the birthrights of their constituents for less even than a mess of pottage. The courts must see to it that no public grants, and no privileges granted, shall so be construed as to deprive the people of any rights or powers except such as are expressly stated or necessarily implied. In applying this rule I hold that the ordinance referred to did not give the telephone company any such exclusive right as it claims; and I am further of the opinion that under its charter powers, and under the corporation ordinance, the Knoxville Street Railroad Company has the right to propel its cars by the single trolley electric system, or by any other the city has authorized or may authorize.

TELEPHONED CONTRACT.

PADDOCK-HAWLEY IRON CO. VS. A. PULLIS ET AL.

This was a suit for $572.34, in a contract made by telephone. The plaintiffs received judgment, when a motion for new trial was made by the defendant. Judge Valliant, of St. Louis, in overruling the subject, said:

"Contracts by telephone," says the Court, "when proven, are as binding as any other contract; but the practical difficulty lies in the uncertainty of the proof, and this uncertainty is chiefly on the point of identifying the person with whom the witness held the telephonic communication.

"When a message by telephone has been received, there are many circumstances which may indicate who the person is that has spoken. But while some of these circumstances have been shown, there is no proof as to who the person is. It has, for example, been held that testimony of a witness to the effect that he was in the habit daily of having communications by telephone with a practical person, knew the number of the telephone and recognized the voice of the person, was evidence tending to prove the identity of the person who was in that case alleged to have made the contract. In this case at bar the defendant's testimony was to the effect merely that he called by telephone a number and asked who it was, and the answer came back that it was the Paddock-Hawley Iron Company. Prices were discussed, but no attempt was made to identify the person at the telephone who made the contract. Even if there had been no testimony to the contrary, this would not have been sufficient to justify the conclusion that it was the plaintiff.

"It has never been held, as far as I am aware," continues the Court, "that a telephone message merely purporting to come from a certain party, but with no evidence of identification, was binding on such party.

"In this case, however, the evidence on part of the plaintiff was positive to the effect that there were but two men connected with the plaintiff's concern who had authority to make such contracts, and that neither of them ever heard of this telephone communication until after the controversy arose. By rules of evidence applicable to this case the plaintiff is entitled to recover, and motion for new trial overruled."

ALTERNATING CURRENT LITIGATION.

GANZ & CO. VS. THE EDISON ELECTRIC LIGHT CO.

A remarkable complaint was filed in the United States Circuit Court this city on May 3, entitled "Ganz & Co., Eisengiesserei und Maschinenfabriksactiengesellschaft in Ofen, against the Edison Electric Light Company." Ganz & Co. have their headquarters at Buda-Pesth, Hungary, and own the system for distributing electricity by means of alternating currents of high tension, known as the Zipernowsky-Deri-Blathy system.

The complaint of Ganz & Co alleges that in 1886 an agreement was made with the old Edison Electric Light Company whose obligations have been assumed by the present company, by which the Edison Company was to introduce the system into the United States, and that $5,000 was paid the complainant on account of the agreement.

Ganz & Co. now allege they have discovered that the representations made to them when they transferred the system were false and fraudulent, and their object was to prevent the introduction of the system here. Endeavors have been made, it is further alleged, to create the impression that the alternating current is deadly and unfit for commercial use, and to bring such currents and systems into disrepute.

The complaint prays that Ganz & Co. may be released from the agreement and awarded proper damages.

ELECTRICITY AS A MANUFACTURED ARTICLE.

COMMONWEALTH OF PENNSYLVANIA VS. PHILA. ELEC. LIGHTING CO. ET AL.

At Harrisburg, Pa., Judge Simonton handed down two opinions last Wednesday in the Commonwealth cases against the Philadelphia Electric Lighting Company and the Brush Electric Light Company of the same city. Both of these companies claim to be manufacturing concerns, and as such, exempt from taxation under the recent act taking the tax off from manufacturing companies. The opinions discuss at great length the means by which electricity and electric light are produced, and quote extensively from the testimony of Professor Henry Morton, President of the Stevens Institute of Technology, whose testimony as an electrical expert was taken in these cases.

But Judge Simonton adheres to his opinion reached in a similar case about a year ago, that producing electric light is not a species of manufacture. He held that neither electricity nor electric light was a material substance; that there could be no manufacture unless some material substance was produced. It is expected that these cases will be argued in the Supreme Court on appeal at its meeting in June. In these cases a great deal of evidence was taken to show the unequal operation of the present tax laws upon different corporations. The lack of uniformity, it was claimed, made the tax unconstitutional. Judge Simonton, however, sustains the constitutionality of the tax except as to the amount involved on patent rights granted by the United States, which he holds are not subject to taxation. Upon this point the Attorney General may possibly appeal. The full amount of the Commonwealth's claim against the Philadelphia Electric Lighting Company is allowed, with interests and cost; but in the case of the Brush Company the amount is largely reduced by the decision as to the invalidity of the tax on patent rights.

OBITUARY.

Daniel L. Gibbens.

Daniel L. Gibbens, formerly one of the Subway Commissioners, died in this city on May 2 of pneumonia. A week ago Thursday he was a guest of Assemblyman Frederick S. Gibbs. Just before retiring he sat in front of an open window talking with Mr. Gibbs, who warned him of the danger of sitting in a draught. Mr. Gibbens said he did not take cold easily. The next day he was laid up with a cold and chills. Last Wednesday pneumonia set in. Mr. Gibbens was born in Waltham, Mass., thirty-one years ago, graduated from Columbia College and Law School, and in 1879 became teacher in a school at Boston, of which his father, E. A. Gibbens, was principal. He afterward became private tutor to the son of Roswell P. Flower, and upon the death of young Flower, private secretary to the father, who was then in Congress. In 1882 when Mr. Flower was in the race for the nomination for Governor, Mr. Gibbens was a prominent figure in Syracuse, and managed Mr. Flower's headquarters. He was also in charge of Mr. Flower's headquarters in Chicago in 1884. Mr. Gibbens had been studying law with more or less ardor all this time, and was appointed counsel to the Subway Board when Mr. Flower was a Subway Commissioner. When Mr. Flower resigned this place in 1886 he recommended Mr. Gibbens as his successor, and Gov. Hill appointed him. Mr. Gibbens became the leading spirit of the Board, and his encounters with Mayor Hewitt furnished a number of lively incidents until Mr. Hewitt declined to sit any longer with the Board. About three months ago Mr. Gibbens resigned his office, and since that time he has been the junior member of the law firm of Kennison, Crain, Alling & Gibbens. He had kept up his connection with electrical interests to the last. His remains will be removed to his mother's house at Fordham, where the funeral will be on May 5. The interment will be in the family plot in Boston, where Mr. Gibbens's father was buried six weeks ago.

Major Otto E. Michaelis.

Major Otto E. Michaelis, formerly Commander at the Watervliet arsenal, New York, died on May 1, at the United States arsenal in Augusta, Me., where he had been Commander for nearly three years. A few months ago he was promoted to the rank of Major, although only 46 years old. At the breaking out of the war he enlisted in the Twenty-third New York, serving three months, and then entering the signal corps as Second Lieutenant. Afterward he was transferred to the ordnance corps. In 1864 he was promoted to First Lieutenant, and in 1874 to Captain. He was the first private citizen to pass a successful examination for this service. For ten years, from 1875 to 1885, the Major served in the West with Gen. Terry and Gen. Miles, being on the former's staff, and being chief ordnance officer in the department of Columbia and Dakota. He was also at different times stationed at Frankfort, Waterford, and Watervliet arsenals. He was an expert in engineering and electrical matters, being one of the founders and Vice-President of the American Institute of Electrical Engineers, of which he was a most valued officer, taking the keenest interest in its welfare and prosperity. He was a broad man, of many tastes and sympathies. He was an expert and an authority on whist and chess, and was a member of the Manhattan Chess Club and the Engineers' Club of this city. In 1857, when only fifteen years of age, he played a series of games at chess with Paul Morphy, the famous player, at the St. Nicholas Hotel. Michaelis had the odds of one rook and won two games.

The death of Major Michaelis is directly due to the physical and mental shock sustained by the drowning of two of his children at Augusta, during the past winter, when he made desperate efforts to save them, and was himself rescued with great difficulty from the broken ice.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued April 29, 1890.

Alarms and Signals:—*Electrical Signaling Apparatus*, J. U. Mackenzie, 426,621. *Electric Fire-Alarm*, C. H. Shaffer, 426,688. *Fire-Alarm Telegraph System*, John Speicher and F. T. Fearey, 426,691. *Circuit Closing Hinge for Electric Burglar Alarms*, W. F. Bleakley, 426,705. *Burglar Alarm*, J. H. Bleoo, 426,706. *Thermostatic Circuit-Closer*, W. H. Chambers, 426,917. *Electrical Tell-Tale Device*, E. F. Roberts, 427,014.

Distribution:—*Potential Controlling Device*, W. Stanley, Jr., 426,573. *Regulation of Electric Motors*, W. Stanley, Jr., 426,574.

Dynamos and Motors:—*Brush and Holder for Electrical Machines*, 426,471. *Regulation of Dynamos and Motors*, W. T. Peel, 426,570. *Dynamo Electric Machine*, J. Wenstrom, 426,576. *Regulator for Dynamos*, J. J. Wood, 426,699.

Galvanic Batteries:—*Galvanic Battery*, F. Gendron, 426,932.

Measurement:—*Device for Measuring Electrical Currents*, T. H. Hicks, 426,499. *Electrical Measuring Instrument*, M. M. Garver, 426,992 and 427,022.

Metallurgical:—*Apparatus for Producing Sheets of Metal by Electro-Deposition*, M. G. Farmer, 426,788. *Electrolytic Apparatus for Forming Copper Ingots*, M. G. Farmer, 426,789.

Miscellaneous:—*Electric Heater*, C. W. Drew and E. R. Francis, 426,437. *Automatic Determining Device for Phonographs*, T. A. Edison, 426,527. *Induction Coil*, A. M. Frankenberg, 426,563. *Switch Apparatus*, M. M. Davis, 426,583. *Electrical Fuse*, H. Tirmann, 426,971. *Circuit-Closer*, H. B. Whitaker, 427,024.

Lamps and Appurtenances:—*Apparatus for Manufacturing Electric Light Carbons*, H. A. Tremaine, 426,479. *Electric Lamp Post*, W. Carroll, 426,660.

Railways and Appliances:—*Electrical Train Signal*, G. D. Burton, 426,522. *Electric Railway*, E. M. Bentley, 426,580. *Electric Engine*, R. W. Thompson, 426,650. *Electric Motor Car*, J. A. Brill, 426,657 and 426,658. *Electric Railway Car*, J. A. Brill, 426,708. *Electric Refrigerating Apparatus for Railway Cars*, M. W. Dewey, 426,781.

Secondary Batteries:—*Method of Making Electrodes for Secondary Batteries*, G. E. Heyl, 426,724.

Telegraphs:—*Message-Recording Instrument*, J. C. Wilson, 426,554 and 426,555. *Quadruplex Telegraphy*, F. W. Jones, 426,591. *Automatic Telegraph*, F. Anderson, 426,749. *Duplex and Quadruplex Telegraph*, F. W. Jones, 426,819. *Telegraph Key*, O. Kleber, 426,941. *Apparatus for Electrical Communication*, J. L. Cutler, 426,989.

Telephones and Apparatus:—*Tablet for Telephones and Clamp Attachment for the same*, J. B. Morris, 426,462.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

THE "NATIONAL ELECTRIC" LIGHTING SYSTEM.

It is understood that the National Electric Manufacturing Company, of Eau Claire, Wis., will soon be represented in the East by a concern to be known as the National Electric Construction Company, which will be well officered and have ample capital. The system is already finding a foothold. The Hotel Normandie, in Washington, will soon be lighted entirely with electricity, and the plant, consisting of one 600-light and one 300-light direct current machines, is furnished by the National Company. The Schaefer 100 volt 16 c. p. lamp will be used. The installation is being made by Mr. L. N. Cox. The machines will be run by two Beck engines. Mr. Cox also reports the installation, recently, of a 250-light plant in the machine shops of Messrs. Dietrick & Harvey, of Baltimore, Md., for the same company.

THE INTERIOR CONDUIT AND INSULATION COMPANY.

The above-named company is rapidly getting into shape to meet the enormous business that has begun to develop in its specialties. Although the factory has been enlarged almost from week to week to keep pace with the demand for the "interior" tubes for wiring, it cannot arrest the accumulation of orders, and it has become necessary to run night and day on this class of work alone. In the meantime, the merits of the tube for underground work have been perceived, and another illimitable field has thus of a sudden opened up. A single order for this underground tubing last week ran over half a million feet, and that was simply a "starter." As an advance in lightness and simplicity the "interior conduit" for underground operations, compared with many older methods, is like the American buggy, compared with the solid, cumbrous English coach; and the cost of such work is reduced to the narrowest minimum. The company has now found it desirable, for the dispatch of business, to have all its executive officers together, and has secured handsome quarters on the second floor of the Western Union building, 16 and 18 Broad street. There a fine suite is being laid out in a tasteful and comfortable manner. The general offices will be under the charge of Messrs. Willard and Little, and President Johnson will occupy a spacious private apartment adjoining. The company has, in fact, already taken possession of these quarters, and the present week will find it at the very height of activity at both ends of the line.

THE WENSTROM CONSOLIDATED DYNAMO AND MOTOR COMPANY.

This Company, recently organized in the city of Baltimore, with E. L. Tunis, president, and Messrs. Enoch Pratt, D. D. Mallory, Robert Rennert, General F. C. Latrobe, Governor E. E. Jackson and Ex-Governor James B. Groome as directors, with a capital stock of $1,000,000, for the purpose of manufacturing and selling dynamos and motors, for street car and other purposes, and doing a general electrical business, having purchased the patent rights of Jonas Wenstrom, of Orebro, Sweden, for his dynamos and motors, for the United States, announces that it is in the market "without fear of competition. These machines have been made in the shops of our predecessors during the last twelve months. A number of them have been put in actual operation and in every case have not only given entire satisfaction, but have far exceeded anything claimed even by ourselves, extravagant as it may appear at first glance."

The Company call attention to a number of testimonials, as well as to the Judges' report (Messrs. F. B. Crocker, C. O. Mailloux, O. A. Moses, J. G. Case and A. A. Knudson) at the American Institute Fair, in 1889; and to the series of tests made by the Electrical Testing Bureau at Johns Hopkins University.

RUBBER GLOVES FOR LINEMEN.

High potentials demand good insulation, and it is now thoroughly recognized that it pays in more ways than one to put the circuits in such a condition that they will withstand all the ordinary assaults of the wind and the weather. But occasions arise when it becomes necessary for linemen to handle open or leaky circuits of considerable voltage, and then no matter how excellent the line wire may be, it is extremely desirable that the men should be properly insulated also. It might seem that this is a mere truism, but truisms in this knowing modern world of ours generally go for less than they are worth; and it must be confessed that the lineman, with his own consent and indifference, has but too often been the victim of neglect in this respect. We are glad, therefore, to see that the Metropolitan Rubber Company, of 649-651 Broadway, this city, is now making a specialty of rubber gloves for linemen. These gloves are somewhat different from the usual make, containing as they do the strictly best grades of rubber, so as to be absolutely non-conductive, and being manufactured with double thicknesses in the parts most exposed to contact. Thus, with superior material in special quantity, they combine unusual flexibility, and are not cumbrous to wear.

These gloves are as cheap as kid, and are now being used by many of the principal companies, among whom may be mentioned the Buffalo, N. Y., Brush Company, the Manhattan Electric Light Company, the United States Illuminating Company, and the Brush Electric Light Company, of New York city. We could heartily wish that every local company running high potential circuits would furnish these gloves to its employees. The item of expense would be infinitesimal, while the insurance secured would be of enormous value. Moreover, we opine that such gloves would have their use in all factories building high potential apparatus.

ALBAMURAL.

Mr. William D. Warner, of 135 Pearl street, Boston, is introducing to superintendents of electric light stations, and to manufacturers in general a new form of *fire-proof* paint, called "Albamural," which is attracting a good deal of attention. Some such paint has long been a felt want, and whitewash, kalsomine, and similar materials have all been tried with varying unsatisfactory results. They nearly all rub off or flake off in time, and soon become very dingy. If oil paint is used, it is impossible to make it fire-proof. "Albamural" comes to the front as a solution of the difficulty, and anyone using it once will be sure to use it always. It is a superior wall coating, giving a smooth, glossy finish, that will not flake, or rub off, is easily applied to any surface, and is much cheaper than paint, kalsomine, and kindred materials. It is the whitest thing ever known, which is largely in its favor where a good light is required. Nearly the entire mixture is composed of a material absolutely fire-proof, thus making it a great fire retardent. Although less than a year since its first appearance in a crude way, on this market, there is now a brisk demand for it. A company with abundant capital has been formed for its manufacture, and the supply will be equal to the demand.

THE WAINWRIGHT MANUFACTURING CO. OF MASS.

The Wainwright Manufacturing Company have sold a 300 h. p. heater to the Wilmington City Railway Company, Wilmington, Del., and a 150 horse power heater to John Post, Jr. & Co., for shipment to Fall River. The Wainwright Mfg. Co., of Mass., is a new corporation, organized in 1889, under Massachusetts laws. Capital, $100,000, with the following officers: Jno. Abbott, President; John A. Loring, Vice-President; Geo. D. Hall, Jr., Treasurer and Manager; Bicknell Hall, Assistant Manager; John F. Fife, Superintendent, and F. H. Lovejoy, Sales Manager. This Company succeeded the Wainwright Co., of Medford, Mass., and continues the manufacture of surface condensers, feed-water heaters, separators, Harvard pump regulators, expansion joints, corrugated copper and brass tubing, besides doing a general foundry and machine business.

The general office and works are situated at Medford, Mass., five miles from Boston, on the western division of the Boston & Maine Railroad, located on the south side of the Mystic River, covering several acres of land, with eight hundred feet of sea wall front, enabling 300-ton vessels to discharge coal, iron and coke into the yard, very close to the foundry.

The buildings consist of a main office, foundry, machine-shop, corrugation-shop, erecting-shop, pattern-shop, blacksmith-shop, stable, rumbling and chipping sheds, besides store sheds for supply and finished work, and is the largest heater and condenser works in the world. Owing to the rush of orders, an electric plant has been installed, in order to work nights.

THE AUTOMATIC FIRE ALARM AND EXTINGUISHER CO. LT'D.

This company have removed their general offices, 294 Broadway, where they have been located since 1875, to 413 Broadway, where they now occupy four floors, divided up into the various executive, central office, store, rooms, shops, etc. They have similar plants and equipments in Boston, Philadelphia, etc. S. G. Babcock is president; E. O. Richards, secretary; and J. P. Curtis, treasurer.

THE FORT WAYNE SLATTERY ALTERNATING SYSTEM.

The Fort Wayne Electric Company have prepared and issued the following list of the largest Slattery induction plants put in by them:

Brainard, Minn., Light and Power Co., 600 lights; Beaumont, Tex., Ice, Light and Refrigerator Co., 600 lights; Central Electric Light Co., Chicago, Ill., 4,000 lights; New Glasgow, N. S., Electric Co., 600 lights; Consumers' Gas Co., Danville, Pa., 600 lights; Electric Improvement Co., San Francisco, Cal., 6,600 lights; Eau Claire, Wis., Brush Electric Co., 1,000 lights; Jenney Electric Light and Power Co., Fort Wayne, Ind., 1,000 lights; Galena, Ill., Electric Light Co, 600 lights; Grinnell, Ia., Electric Light Co., 600 lights; Manhattan Electric Light Co., New York City, 21,000 lights; Citizens' Electric Light and Power Co., Houston, Texas, 2,000 lights; Halifax, N. S., Gas Light Co., 1,950 lights; Lebanon, O., Light, Heat, Fuel and Power Co., 600 lights; Fargo, Dak., Incandescent Light Co., 600 lights; Madison, Wis., Electric Co., 1,000 lights; Queen City Electric Light and Power Co, Dallas, Texas, 2,000 lights; Ruch Bros., Columbia City, Ind., 600 lights; Saginaw, Mich., Electric Light and Power Co., 1,000 lights; Swift & Co., Kansas City, Mo., 600 lights; Swift & Co., So. Omaha, Neb., 600 lights; Swift & Co., Chicago, Ill., 2,000 lights; M. W. Simons, Plymouth, Ind., 1,000 lights; Utica, N. Y., Electric Light Co., 3,000 lights; L. D. Cardwell, Harrodsburg, Ky., 600 lights; New Iberia, La., Electric Light and Power Co., 600 lights; Pittsburg, Kan., Gas Light and Power Co., 600 lights; Allen Apartment Building, Chicago, Ill., 600 lights; Feeble Minded Institute, Fort Wayne, Ind., 600 lights; Northwest Electric Construction and Supply Co., St. Paul, Minn., 2,000 lights; Jenney Electric Light and Power Co., Pekin, Ill., 600 lights; Detroit, Mich. Electric Light and Power Co., 5,600 lights; Citizens' Electric Light and Power Co., East St. Louis, Ill., 600 lights; City of Ironton, O., 2,000 lights; Middletown, N. Y., Electric Light Co., 1,650 lights; Wyandotte, Mich., Electric Light Co., 600 lights; Waterhouse Electric Co., Baltimore, Md., 2,000 lights; Stellar Electric Co., Boston, Mass., 1,000 lights; Woodstock, Ont., Electric Light, Power and Railway Co., 650 lights; Port Hope, Ont., Electric Light and Power Co., 650 lights; Bloomington, Ill., Electric Light Co., 1,000 lights; Champion Electric Co., Springfield, O., 1,000 lights; Thomson-Houston Electric Light Co., Charleston, Ill., 600 lights; Kingston, N. Y., Electric Light Co., 2,000 lights; Excelsior Electric Co., Harrisburg, Pa., 2,600 lights; Fort Wayne Electric Co., Evansville, Ind., 1,000 lights; Northern Indiana Prison, Michigan City, Ind., 1,200 lights; North New York Lighting Co., N. Y., 600 lights; St. Clair Steam Supply and Electric Light Co., Belleville, Ill., 1,000 lights; Decatur, Ill., Electric Street Railway Co., 600 lights; Louisiana Electric and Power Co., New Orleans, La., 7,000 lights; Stockton, Cal., Gas Light and Heat Co., 1,000 lights; City of Galion, O., 800 lights; Lowville, N. Y., Electric Light and Power Co., 650 lights; Yonkers, N. Y., Schuyler Electric Co., 1,000 lights; Jersey City, N. J., Electric Light Co., 3,000 lights; Armour Packing Co., Kansas City, Mo., 1,200 lights; Manhattan, Kan., Electric Light Co., 650 lights; Electric Improvement Co., San Jose, Cal., 1,000 lights; Jenney Electric Light and Power Co., Logansport, Ind., 600 lights; Leetonia, O., Electric Light and Power Co., 600 lights; Cincinnati, O., Electric Light Co., 3,000 lights; Corporation of Collingwood, Ont, 650 lights; Brockville, Ont., Incandescent Electric Light Co., 1,000 lights; Stroudsburg, Pa., Electric Light and Power Co., 650 lights; Haddonfield, N. J., Electric Light Co., 1,300 lights; Saratoga, N. Y., Gas and Electric Light Co., 650 lights; Bridgeport, O., Electric Light and Power Co., 650 lights.

SAWYER-MAN LAMPS.

The Queen City Electric Light Company, of Gadsden, Ala., in a letter of April 26 to the Sawyer-Man Electric Company, says :—

"We have something wonderful in the way of an incandescent lamp to report to you. On July 4th, 1888, we started our incandescent dynamo. Among the lamps in the station was one over the engine, which has been running all night long every night since and is still running now. Counting from July, 1888 to July, 1889, we have 365 days, and from July 4th, 1889, to May 1st, 1890, we have 300 days more, which together makes 665 days of 12 hours=7,980 hours. No doubt some will discredit this statement, but nevertheless it is true. The above described lamp is a Sawyer-Man 16 c. p. 110 voltage."

R. A. KELLOND.

Mr. R. A. Kellond has opened offices at rooms 27 and 28, No. 63 Broadway, and will there carry on a patent soliciting agency, with branches in Montreal and Washington. Mr. Kellond has an intimate familiarity with Canadian as well as American patent practice, and is well equipped in every way for his work. He has already made a specialty of electrical work, and has had several important cases in hand.

CROCKER-WHEELER ELECTRIC MOTOR COMPANY.

Mr. T. McCoubray, secretary and general agent, has issued the following notice :—"To meet the extraordinary demand for our motors, we have removed to the building bounded by Washington, 13th and 14th streets, New York. We have been compelled heretofore, to ask indulgence in billing orders. With our vastly increased facilities, we are now able to handle all business promptly. We solicit your orders, and invite correspondence on electrical engineering subjects."

The Company's perfected motors are meeting with very pronounced success, and a large number of them are already in operation on the various systems all over the country.

CHADBOURNE, HAZELTON & CO.

Chadbourne, Hazelton & Co., formerly general agents of the Sprague Co. for Pennsylvania, Maryland, Delaware and Southern New Jersey, having severed that connection, have now completed arrangements with the Wenstrom Consolidated Dynamo and Motor Co. of Baltimore as sole selling agents for the United States.

The Equitable Electric Railway Construction Co., A. H. Chadbourne, president, W. Hazelton, 3d, secretary and treasurer, and W. A. Stadelman, chief engineer, will continue to transact as heretofore their general construction business for railways, isolated plants, etc., for both lighting and power purposes.

The offices of the concerns above named are at 416-18-20 Walnut street, Philadelphia, and the warerooms are at 28 South Fourth street.

THE MASON PRIMARY BATTERY.

Mr. J. H. Mason, of 63 Broadway, is lighting the library of Prof. Ives' house at Rockville, Conn., with two of his 20 c. p. lamps, using 14 of his No. 11 cell. The room is 18 x 20 feet, and is well lighted by this means.

Mr. Mason has been appointed sole agent for the electrical department of the Kato Manufacturing Company of Jersey City, who make a specialty of portable lamp ware.

ENGLISH, MORSE & CO.

English, Morse & Co., Engineers of Kansas City, Mo., report recent sales of power plants as follows: Pittsburg Gas Co., Kan., one 125 h. p. "Ideal" engine; Boonville Electric Light Co., of Boonville, Mo., one 80 h. p. "Ideal" engine, with steel boiler and complete plant; Abernathy Furniture Co., K. C., Mo., one 30 h. p. "Ideal"; engine, with boiler, dynamo, motor and complete plant; Girard Electric Light Co., Girard, Kan., one 60 h. p. steel boiler. Also numerous orders for Lahman-Kirkwood rocking grates, "Leather Link" belting, Hill clutch pulleys, Worthington steam pumps, etc., etc.

WESTINGHOUSE LIGHTING APPARATUS.

The Westinghouse alternating current arc light system is growing in popular favor very rapidly. The company is constantly in receipt of complimentary letters which testify to the many advantages of the system, and the productive capacity of the Pittsburgh works is tested to its very utmost. Of late, many inquiries have been made for a smaller dynamo than the ordinary sixty light machine. To meet this demand, the company is now manufacturing a small 25 light dynamo of a unique and very pleasing design. The Westinghouse alternating current arc light apparatus has been contracted for during the month of April by electric light companies at the following central station plants : Troy, N. Y., 60 ; Saratoga, N. Y., 60 ; Salt Lake City, Utah, 25 ; Evanston, Ill., 120 ; Joliet, Ill., 60 ; Martins Ferry, O., 40 ; Uxbridge, Mass., 60 ; Oxford, Ohio, 60.

During the month of April, the Westinghouse Electric Co. sold its alternate current incandescent apparatus for central station electric lighting plants in the following places : Portsmouth, Va., 1,500 lights ; Saratoga, N. Y., increase, 1,500 ; Salt Lake City, Utah, 500 ; Mt. Morris, N. Y., 500 ; Brookline, Mass., 900, increase ; Johnstown, N. Y., 500, increase ; Springfield, Mass., 3,000 increase ; St. Thomas, Ontario, 750 ; Ouray, Col., 750 ; Sherman, Texas, 750 ; Detroit, Mich., 6,000 ; Susquehanna, Pa., 750 ; Elmira, N. Y., 750 inc.

THE GARVIN MACHINE COMPANY.

The Garvin Machine Co., of Laight and Canal streets, N. Y., has recently issued a very complete and well printed, illustrated catalogue of its machinery and machinists' tools of all kinds. It would be hard to name any tool required in an electrical factory or station that is not therein described and shown by excellent wood-cut or outline sketch. The line of milling machines we note to be very large, no fewer than 16 different patterns and sizes being included. The department of screw machines is also remarkably ample, and not less may be said of the drill presses, tapping machines, etc. The section relating to gear cutters is also specially noteworthy. The company invite correspondence, and have a well deserved reputation for care and exactitude in meeting all the conditions and requirements imposed by the highest practice and principles.

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.

Geo. M. Phelps, President. F. R. Colvin, Treas. and Business Manager.

Edited by
T. Commerford Martin and Joseph Wetzler.

New England Editor and Manager, A. C. Shaw, Room 70—620 Atlantic Avenue, Boston, Mass.

Western Manager, W. F. Collins, Temple Court, 225 Dearborn Street, Chicago, Ill.

TERMS OF SUBSCRIPTION, POSTAGE PRE-PAID.

United States and Canada,	per annum,	$3.00
Four or more Copies, in Clubs (each)	"	2.50
Great Britain and other Foreign Countries within the Postal Union	"	4.00
Single Copies,		.10

[*Entered as second class matter at the New York, N. Y., Post Office, April* 9, 1888.]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed*, Editor of The Electrical Engineer, 150 *Broadway. New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

Vol. IX. NEW YORK, MAY 14, 1890. No. 106

What is the truth, is the goal of intellectual mankind in all ages, and its pursuit leads not only to intellectual but also to physical satisfaction.—Prof. Henry A. Rowland.

THERMO-MAGNETIC GENERATORS.

THE economical production of electric energy direct from medium, heat without the employment of a secondary such as a prime mover, has led many to search in the direction of the thermo-pile for the solution of the problem; and not a few are at the present time occupied in this field. The recent investigations into the thermo-magnetic properties of iron have, however, somewhat turned the tide of the work of electrical inventors, some of the most prominent of whom have recently given their attention to the thermo-magnetic generator and motor, among them being Mr. Edison and Mr. Berliner. To these must now be added Mr. Tesla, a little of whose work in this field, though accomplished several years since, we are now enabled to publish for the first time. It is evident, from the description on another page, that Mr. Tesla early recognized the cardinal principles to be observed in order to obtain the maximum efficiency of which motors of this class are capable, and the arrangements which he adopted for that purpose are well calculated to attain the objects desired. The criticism has been truly made that thermo-magnetic motors can, at best, be but comparatively inefficient converters of energy, on account of the small range of temperature through which the heated medium is worked; and the inventor has recognized this fact by the rather anomalous employment of steam as a cooling medium, which, after having performed this function and absorbed additional heat, may be employed for other useful purposes. Though no commercially practicable thermo-magnetic apparatus has yet been forthcoming, it is not too much to hope that, with the progress already made, a machine of commercial value may be looked for at no distant date.

REPORTS ON THE PARIS EXPOSITION.

Although much has been said and written on the electrical work displayed at the recent Paris Exposition, no systematic attempt has, so far, been made to co ordinate the various exhibits and to subject them to a critical analytical treatment. The material available for such a work was quite ample and well worthy of consideration, and our readers will therefore be pleased with the information embodied in the report of Mr. Carl Hering, who was one of the American Jurors of Awards of the Electrical Section of the Exposition. The first section of Mr. Hering's report which we print in this issue contains a complete summary of the exhibits of electrical conductors, both bare and insulated, and presents a good résumé of the state of the art at the present day. It is gratifying to note that notwithstanding the youth of the art in this country, American insulated wires, as a rule, carried off prizes. The figures relating to the various bare conductors of high tensile strength manufactured in France are worthy of the attention of our manufacturers.

BOSTON MEETING OF THE ELECTRICAL ENGINEERS.

After a lapse of six years, the American Institute of Electrical Engineers is again to hold an annual meeting outside New York. When the meeting was held in Philadelphia in 1884 at the Electrical Exhibition, the society had but just been formed and the membership was small. To-day it shows all the signs of growth, prosperity and usefulness, and the mere fact that in New England alone it now has nearly as many members as it had all told in 1884, promises a large attendance in Boston next week. We print elsewhere the excellent programme submitted by Mr. R. W. Pope, the secretary, and are glad to see so large a list of good topics to be treated by well-known engineers. A subject that will doubtless be taken up, is that of "American electrical units," and one or two interesting committee reports may probably be looked for also. There is, moreover, much to be seen of electrical interest in Boston, and the Electric Club emphasizes its hospitality with a dinner and a paper on one of the most important questions of the day. Altogether, the Institute's Boston meeting should be most pleasant and profitable.

THE PRICE OF COAL AND THE TARIFF.

In the past a considerable part of the advantage possessed by European manufacturers in competition with those of the United States has lain in their cheaper coal. The changed conditions of coal supply have now, for the most part, reversed the situation in that regard, the advantage now lying on this side of the Atlantic. While the price of coal has been advancing in Europe, it has been greatly diminished in America during the past ten years, mainly through the discovery and opening up of large deposits of semi-bituminous coal in the middle and southern states. This coal has well nigh superseded anthracite as a steam coal; and, judging from the columns of the coal trade journals, a further indefinite increase of the supply may be counted upon. $4.75 per ton may fairly be taken as the price of steam coal in New York in 1880. It is now reported from $2.75 to $3.50—sales averaging at between $3.00 and $3.10. A sale of 60,000 tons at $2.75 to a railway company is said to have been made recently.

Meantime prices have so advanced in Europe that the export of coal to the Continent has been contemplated by large operators here as a feasible outlet for the excessive production in this country.

A valued correspondent, conducting a factory at Antwerp, informs us, under date of April 11, that the finest steam coal, *briquettes*, had advanced 60 per cent. in price since a year ago, while common steam coal had risen fully 100 per cent. Prices at Antwerp, early in April, reduced to dollars and cents and to gross tons, were as follows: Anthracite, $5.77; Briquettes (best form of steam coal) $4.93; common steam coal, $4.43. While so extreme an advance may not be fully maintained, it is quite certain that this country will henceforth possess a distinct and considerable advantage in the price of fuel for manufacturing purposes. Its high cost in Europe must seriously modify the conditions of manufacturing there, and effect a dislocation of trade.

Now American manufacturers can reap the full benefit of their cheaper coal, and take their legitimate position in competition with Europe in the markets of South and Central America, Australia, Asia and Africa, only by standing on an equal footing in other respects.

Free raw materials are obviously the first and most pressing requisite to clear the path of our manufacturers and exporters. The most intelligent and far-seeing of them have demanded the removal of duties on the materials of manufacture in no uncertain voice. The condition of coal supply accentuates their position and adds another argument to the many sufficient ones already adduced in support of it.

It is hardly conceivable that the McKinley view, to wit: that foreign trade is a bad thing to have, will for any length of time be taken seriously by American citizens. They will not indefinitely neglect their advantages and opportunities.

Graphic Demonstration of Electric Potential.

To students whose grasp of mathematical conceptions is limited, the fundamental ideas regarding the nature of what is termed electric potential, are apt to be a stumbling block which seriously interferes with progress in some of the most interesting branches of the science. A graphical explanation of the nature of electric potential based on its defined properties will, therefore, go far towards opening the way to a clear understanding of the notion embodied in electrical "potential." Prof. Mayer's elegant demonstration given on another page proves by a well known analogy that the curve expressing the work done in approaching two bodies charged at a given potential, is quite analogous to that made by the steam engine indicator, being of the nature of an hyperbola.

Electric Motors vs. Steam Locomotives.

Mr. J. C. Henry contributes to our columns this week a very interesting and suggestive article on some of the points of difference between electric locomotives and steam locomotives. This subject is not nearly so much one of the future as many people suppose, but is one that is already being freely discussed from a variety of practical standpoints. Electrical engineers realize that when they have done as much in perfecting the electric locomotive as mechanical engineers have done upon the steam locomotive, they will have something to be proud of. Meanwhile they are at work, and will be heard from. Mr. O. T. Crosby will, it is understood, contribute a most valuable paper on the limitations of steam and electricity in "teletravel," at the Boston meeting of the American Institute of Electrical Engineers next week.

Dr. Lodge's Lightning Arrester.

In several of our recent issues we have described new forms of lightning arresters, embodying very ingenious construction, in which one of the principal objects aimed at was the avoidance of all inductive resistance which might offer an obstruction to the passage of the lightning discharge. But as again illustrating the great flexibility of the principles of electricity in practical application, our readers will note elsewhere an arrangement designed for this purpose by Dr. Oliver J. Lodge, in which coils of high self-induction are employed for the purpose of *compelling* the discharge to jump the air gap. This construction adopted by Dr. Lodge is a logical sequence of his "alternative path" experiments which deservedly attracted so much attention at the time. These experiments, it will be remembered, were carried out in a great variety of forms, and some surprising results were obtained. It may be of interest to recall the fact that Faraday also observed and described the phenomenon which has been so well elaborated and utilized by Dr. Lodge.

Primary Battery Combinations.

Given a certain number of substances available as active and depolarizing materials in a primary battery, a very simple calculation will show the number of combinations that can be effected in this direction. The variety resulting from the calculation is, however, so large, that, though probably hundreds of combinations have been tried, there still remain a large number for experiment. And that there is still virgin soil open to cultivation is evidenced by the description of a new battery to which Prof. A. E. Dolbear drew attention in our last issue. The high electromotive force obtained is quite remarkable and is no doubt due to employment of an alkali as the active electrolyte in combination with the powerful acid depolarizer. It is barely possible, also, that the difference of potential created between the alkaline and acid solutions themselves may aid in raising the E. M. F. to the points observed. There can be but little doubt that more than one of the many waste products, especially of chemical manufactories, could be usefully applied in batteries. We have but recently been advised of another striking example of this and shall probably soon be able to give fuller details.

ELECTRIC MOTORS VS. STEAM LOCOMOTIVES.

BY JOHN C. HENRY.

In a recently published paper by Dr. Louis Bell on the subject of electric railways the popular opinion that steam locomotives are wasteful engines is in a measure combatted by reported tests and comparisons. I can cannot help thinking that Dr. Bell's conclusions are erroneous in this respect, and will give some reasons for this opinion.

I have no wish to disparage the work of the engineers who developed the locomotive. To me they move to-day as living monuments to nameless thousands of students and mechanics whose limbs have failed and whose brains have been worn out in their efforts to improve this almost human machine. Did it ever occur to to the reader to estimate at what cost the locomotive of to-day has been developed? Consider the thousands of lives that have been lost in railroad accidents, each of which developed perhaps a single fact that a certain portion of the machine was faulty or weak, or that metal of a certain shape or in a certain position would deteriorate rapidly, that one portion was too heavy, and another too light.

Is it any wonder that the novice who carries his wooden model into the presence of the railroad official usually finds that gentleman averse to changes, and apparently disinterested, or "cranky," and retires with the opinion that no one outside of the "ring" can have his devices or improvements adopted. Every country section has such working individuals; add to these vast numbers the thousands employed with the locomotive, all with the chief aim as their greatest desire to improve and surpass their fellows, would the estimate that the present development of the locomotive had cost 100,000 lives be unreasonable? I think not.

Such considerations raise the question, Is it worth the price? If the Emperor of China's objection to the introduction of the Steam Horse in his domains are based on any such considerations, it is not wholly without reason; but science knows no sentiment. Our present existence and future welfare depend upon the husbanding of energy. The time will come when it will all be exhausted, whether physical, mental or mechanical. With the latter I will attempt to deal. The point I wish to prove is that notwithstanding this immense cost and the improvements suggested by nearly seventy years' experience, the popular locomotive of to-day is an unscientific, extravagant machine, and that on the points of economy, ease of manipulation and safety, it cannot compare with the new-born electric motor, and is distanced by the stationary engine.

To deal with the subject properly, comparisons must be made and weaknesses pointed out. Stationary engines have automatic cut-offs; locomotives depend upon manually operated ones, which are necessarily intermittent and much less sensitive to varying conditions than a spring would be to a changing load. Poor regulation means a waste of steam. Stationary engines have balanced valves; the steam pressure against them is equalized and they consequently move freely. Locomotives, owing to their peculiar construction, require the valves to be on top of the cylinders, which precludes the use of anything but slide valves, which have the full weight of the steam pressure bearing against their movement. Owing to the compact requirements, locomotive boilers have much less heating surface than stationary boilers; this necessitates the use of a forced draught, which means that the larger portion of the heat passes out of the stack, the boiler absorbing the most intense heat only. Stationary boilers are usually covered with several courses of brick to confine the heat. This would be impracticable on a locomotive; they are usually covered with thin wood lagging, the detrimental effects from which in varying temperatures are great. I have frequently seen locomotives lose steam at the rate of about a pound per second when passing through snowdrifts. The loss of fuel is very considerable in bad weather or when running against the cold winds.

I question the correctness of the reported tests in Dr. Bell's paper; they seem as unreasonable as some I once made with an electric motor. It appeared to show an efficiency of 115 per cent. I have carefully watched the tests of some of the finest locomotives in the West. The best result I have ever known was a consumption of 8 lbs. of coal to the h. p. hour, and this was under the most favorable conditions. The same locomotive showed a consumption of over 20 lbs. of coal to the h. p. hour when working "down in the corner."

In the absence of other accurate data on this subject which I expected from the article referred to I investigated the startling economical reports of the performance of the Elevated Railway locomotives. I found they consumed from 50 to 90 lbs. of anthracite coal per mile, run with five coaches. Striking the average at 70 lbs., and estimating the average weight of the trains at 250,000 lbs. to move this weight 100 miles would require an expenditure of but 276 h. p. hours; dividing this into the amount of fuel actually consumed would show a consumption of 25 lbs. of coal to the h. p. hour. This estimate is based upon a perfectly level track in good condition and no stops. The extra amount of energy lost in ascending grades is partially regained on the descent, and a certain proportion is lost by the car brakes. Some years ago Mr. Frank J. Sprague carefully investigated these losses, and, I think, placed them at about 40 per cent. of the total, which seems to be fair; this would leave the result that the New York Elevated Railway locomotives consumed, on the average, about 15 lbs. of coal to the h. p. developed per hawes. We all know that stationary engines are on the market that will not consume over one-fifth of this amount of fuel for the same power developed.

There is very much to be said in favor of the rotary movement of electric motors as opposed to the reciprocating steam engines. I am told that Mathias Baldwin, founder of the celebrated locomotive works, had the idea haunting him throughout his life, that the locomotive should have rotary engines. "Appleton's Applied Mechanics," under the head of "Steam Engines," has the following: "It has been said that there is scarcely an engineer of much experience who has not designed at least one rotary engine." The tendency of everything is to rotation; this is exhibited so prominently in nature and art that—pardon the thought—it may be the coming man will rotate.

In locomotives it has been found impracticable to put them in running balance. Suppose we were to support one on its frame, leaving the drivers free to revolve, and, then open the throttle; the locomotive would immediately commence a rocking motion, and the tendency to leave the foundation would increase as the square of the speed.

Some years ago, Mr. McLoud, engineer of tests of the Pennsylvania Railroad Co., investigated this evil effect, and calculated that one of their latest designs of locomotives, when running at full speed, was delivering trip-hammer blows at each revolution of the drivers equal to the force of 60 tons. Among thoughtful railroad engineers the opinion was pretty general that the horrible Ashtabula Bridge railroad accident which caused about 80 deaths and 60 wounded was primarily due to this unscientific construction which is still in the steam locomotive, but absent in the electric motor.

ELECTRICITY AS A "BUG" DESTROYER.

BY FOREE BAIN.

The Electrical Engineer of April 30, contained editorial comment on an article in the *Manufacturers' Record* in regard to catching bugs, moths, birds, etc., by the use of the electric arc light. Please allow me to make a suggestion by relating an incident that occurred in the early days of the electric lighting industry.

In the fall of 1879 I put five Maxim 5,000 c. p. arc lights in the gardens at the Highland House, Cincinnati. The first few nights they went as well as could be expected, and everybody seemed pleased. Finally, one day after the lights had been in place only a short time, the circuit was inadvertently reversed and the lamps burned "upside down" for one night. That night all the elite of the city were on the Hill, but they did not remain long. The heavens were beautifully illuminated by the lights, and this attracted more bugs than people. The globes of the lamp became full of bugs in a short time. Then began the process of boiling and cooking bugs, and this I can assure the readers of the ENGINEER was not pleasant to the olfactory organs. It was estimated that at least one ton of bugs had perished that night by their folly in "tackling" the electric light.

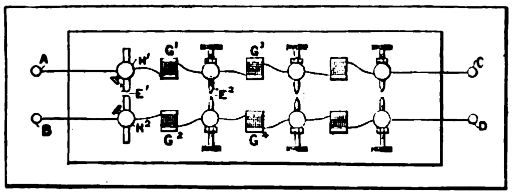
It seems to me that in the article I have referred to above, there is a disposition to encourage the use of electricity as a kind of "Mothaline," or "Rough on Rats." I therefore fall in on the popular side, and suggest that, if electric light people desire to do any catching of moths or "bugs," they reverse the lamps. They will get all they want.

DR. LODGE'S LIGHTNING PROTECTOR.

THE very interesting series of experiments on the "alternative path" made by Dr. Oliver J. Lodge, have recently been applied by him to the construction of a lightning arrester, and, in general, as a safeguard against high tension currents. In these experiments, it will be remembered, a static discharge was found to prefer to jump an air space in preference to passing through a straight conductor of very low resistance. The explanation given for the phenomenon is that the self-induction or electro-magnetic inertia of the conductor offers a virtual resistance to the sudden passage of a current, greater than that of the air gaps, which is consequently jumped.

In applying this principle Dr. Lodge has still further increased the resistance to the passage of the charge through the metallic conductors by making them in the shape of coils having a high self-induction.

One form of the new arrester is shown in the accompanying engraving.[1] Here A and B are the terminals inserted in the leads, or A is connected with the line wire and B with earth; C D are terminals connected with the instrument to be protected, or C with the instrument and D with the earth, or C with the instrument and D left insulated as desired. E^1, E^2, etc., are air-gaps or insulating spaces; G^1, G^3, etc., are self-induction coils, consisting of gutta percha covered wire coiled up on bobbins.



DR. LODGE'S LIGHTNING ARRESTER.

The action of the arrangement is as follows: The ordinary currents, which it is intended to transmit through the apparatus to be protected, traverse the connecting wires or self-induction coils, G^1, G^3, etc., and do not jump any of the air-gaps. But lightning, or any other foreign and violent currents which may accidentally have got into the leads, will jump one or more of the series of air-gaps, and be thus diverted from the instruments or lamps to be protected.

Thus the insulating spaces or air-gaps may be arranged so that the greater portion of a violent discharge will jump the first, E^1; a certain fraction, say a tenth of the remainder, will jump the second, E^2, and so on; the amount finally permitted to go through the protected instrument being thus reduced to any desired amount.

According to Dr. Lodge it may be well to set the air-gaps or insulating spaces of different widths; for instance, the first having broad, rounded ends wider apart than the second, exposing larger surface and capable of easy examination and replacement in case of damage by a flash; the second having small rounded ends or points close together, and capable of minute adjustment by screwing up with lock-nuts, the third still closer and finer. It may also be well to vary the connecting coils, using thicker and more highly-insulated wire for the earlier coils, and thinner for the latter.

THE ACTION OF THE TOEPLER-HOLTZ MACHINE.

BY PROF. MARSHALL HENSHAW, AMHERST COLLEGE.

In a leaflet recently issued by Messrs. Queen & Co. there appears a proposed explanation of the action of the Toepler-Holtz machine, which, it seems to me, is hardly satisfactory. The explanation given is identical with that of Mr. Eaton published in *Science* in 1884. This journal at about the same time also published an explanation which differs materially from the one cited.

As neither of them is satisfactory to some, I submit the following as appearing to me simple and adequate, using the language of the two-fluid hypothesis, which we are obliged to employ for the want of a better.

It must be borne in mind that induction never takes place *on*, but *through* a non-conductor. The dielectric may be a single substance or many. In this machine, as seen in the illustration, it consists of two plates of glass and two of air. The initial action is the friction between the brushes and the buttons. Let *a* be the brush on the right upper quarter of the figure; *b* the button which first reaches *a* in turning the plate in the direction of the hands of a watch; *c* the plate of foil and paper—the armature—on the posterior face of the stationary plate opposite *a*, and in metallic connection with it, and *d* the comb and discharger in front of *c*. Let a', b', c' and d' be the corresponding parts on the left, and $e\,e'$ be the cross bar with its combs.

c'
o
JAS. W. QUEEN & CO. PHILA.

THE ACTION OF THE TOEPLER-HOLTZ MACHINE.

When *a* and *b* come in contact, the friction excites electricity, and one of them must become positive and the other negative. What determines which shall be positive is unknown. It is sometimes one and sometimes the other. Suppose *a* is positive. As soon as *b* passes away, the positive of *a* is set free, and spreads to *c*, which thus becomes positive. Now *c* by induction draws negative electricity on to the revolving plate and repels positive to the discharger. Thus the revolving plate, as each point passes *d*, on a ring as wide as the comb is long, becomes charged with negative electricity. But at the same instant when *a* touches *b*, a' strikes b', and if *a* is positive, by a law of nature, a' must be negative. From it c' becomes negative, and draws from

---

[1] London *Electrical Review.*

d^1 positive on to the revolving plate and repels negative to the discharger, and a ring of the revolving plate is charged with positive electricity.

But if the ring passing d, and charged with negative electricity comes in that state to a^1, which is also negative, all action must cease. To prevent this the cross bar e e^1 with its combs is placed nearly at right angles to the line a a^1, and neutralizes the rings of the plate, and thus every button meets a and a^1 in a neutral state, ready to go through the same process again. The whole office of e e^1 is to neutralize the parts of the plate as they pass it.

The part of the plate from d to e^1 is always negative, and that from d^1 to e is positive, while the parts e d and e^1 d^1 are neutral. The amount of electricity excited by a single contact of a and b, and of a^1 and b^1 is small, and hence the plate must be rotated a dozen, or more, times before the armatures become fully charged, and the tension sufficient to produce a spark between the discharging rods.

THE RAE "HORN" AMMETER.

The demand which has arisen for instruments adapted to indicate heavy currents has given rise to a variety of forms, not a few of which embody the principle of a movable core acted upon by a solenoid. In order to obtain an instrument which should be direct reading and at the same time have a scale with nearly equally spaced divisions over a large range of current, Mr. Frank B. Rae has designed an ammeter, which, on account of its peculiar construction has been termed the "Horn" ammeter. The accompanying engraving, Fig. 1 shows the new instrument in perspective and the details of its construction are shown in Figs. 2 and 3.

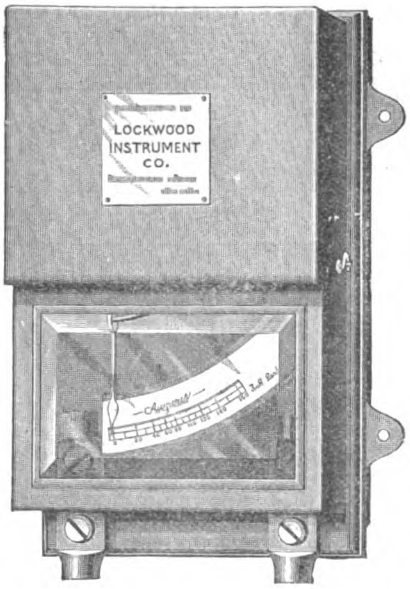

FIG. 2.—THE RAE "HORN" AMMETER.

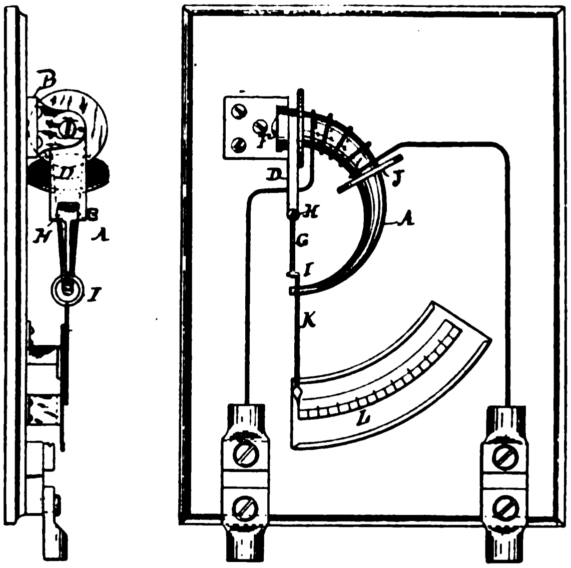
The horn, A, forming the semicircular core piece is supported on a casting, B, and is made of wrought iron with a gradually tapering cross-section. Between the base of the core-piece and the bracket B is placed a plate D, of soft iron, and having a width equal to the large end of the core-piece and a length somewhat greater than the radius of the piece. This plate is interposed between the large end of the core-piece and the bracket, and the whole is secured together by an iron screw F.

The free end of this plate terminates at the centre of a circle, the circumference of which includes the curved piece, and in the end of this plate is mounted, by a hinged joint, a soft-iron armature G. The bearing portion of the latter is enlarged and rounded, as shown, so that it will present practically the same surface to the plate in whatever position the armature may assume under the action of the current. To the free end of this armature-piece is attached a ring I, of soft iron, the ring having an inner diameter equal to the diameter of the curved piece at the point J adjacent to the coils. Attached to the ring I is a pointer K, of light non-magnetic material and this pointer normally rests over the zero-point of the scale L in the form of a segment.

The action of the apparatus will now be clearly understood. Upon the current passing through the coil surrounding the core-piece, the armature and ring will be attracted, and, swinging on its pivot, the pointer will move over the scale and indicate the strength of the current flowing. It will be understood, of course, that the shape of the core-piece A and its variation in cross-section from its point towards its base is such that the attractive effect upon the armature and ring will not be in direct proportion to the strength of the current passing through the coils, but will increase directly as the pull exerted by gravity increases with the angle of swing, so that the movement over the scale is very nearly proportional to the current strength over the whole range. The ammeter, we may add, is made by the Lockwood Instrument Co., of Detroit, Mich.



FIGS. 2 AND 3.—THE RAE "HORN" AMMETER.

SECONDARY, PRIMARY AND STORAGE BATTERIES.

BY E. R. KNOWLES, C. E.

In reply to the very courteous criticism by Mr. Frederick Reckenzaun, of my article on "Secondary, Primary and Storage Batteries," which appeared in THE ELECTRICAL ENGINEER, of April 9th, I would like to say, that there was a twofold object why the terms "primary" and "storage" were assigned "to a class of batteries, namely, primary batteries capable of being regenerated by the action of an electric current"; first, not because "they have thus far acquired comparatively little practical importance," but because they are likely, in the near future, to attain very great importance, and it would be well to have their status clearly defined, namely, that they are storage batteries and not secondary batteries; and second, that the terms "secondary" and "storage" might not be confounded, as they most generally are.

A secondary battery is almost invariably a storage battery, but a storage battery is not always a secondary battery, but may be a primary battery. It is this fact, that "secondary," "storage" and "accumulator" have "been accepted as perfect equivalents" to the utter exclusion of any claims that the primary battery may have, that has caused a great deal of the confusion and litigation of late years. In the suit between the Accumulator company and

the Julien company, it was strenuously contended by the Accumulator company, that no primary battery was possible for use as a "secondary" or "storage battery" or "accumulator," and testimony to this effect by several noted experts was introduced; and yet the facts are quite the reverse, as, to the writer's knowledge, there are several primary batteries capable of doing good work as "storage batteries" or "accumulators," but not as "secondary batteries"; and it is wrong and confusing, to say the least of it, to make the terms "secondary" and "storage" synonymous. Because a bad precedent has been established in this respect, it does not follow that it is proper to persist in it, when once it is seen to be erroneous, and it is not clear that any confusion would result from the assignment of these terms to their proper places, but rather a clearing up of a confusion which now exists. No attempt is made to "steal" anything, but rather to restore to its proper place that which is already stolen.

A clear understanding of the exact status of these three great classes of batteries has another and very important bearing, namely, whether patents taken out for improvements in "secondary batteries" have any bearing at all upon "primary batteries" which may be made in the same, or similar, manner. An attempt was made to re-open the case between the Accumulator company and the Julien company, after a decision had been rendered, on the ground of newly discovered evidence, but the patent which was introduced was decided to be for a "primary" and not a "secondary" battery, although it was for practically the same thing, made in the same way. This is a very important point for the consideration of all who are engaged in inventing and perfecting in this branch of electricity, and who are desirous of accomplishing something which is not covered and crushed out of sight by a monopoly, as it would seem that it is to be.

"Primary" and "secondary" batteries, being two separate and distinct branches of this subject, by legal decree, it would seem that claims for "secondary" batteries would not hold good for "primary" batteries, and that here was a fertile field for inventive genius to work in.

TESLA'S THERMO-MAGNETIC GENERATOR.

The phenomenon that iron loses its magnetic properties suddenly at about a red heat and as suddenly regains them on cooling below that point has long been known, but it is only comparatively recently that advantage has been taken of it for its practical utilization. It is evident that by placing a coil of wire under the influence of a magnet alternately rapidly heated and cooled above the critical magnetic point, induction currents will be set up in the coil, due to the variation of the magnetism of the core.

This principle has already been applied in a number of ways in the construction of what are known as thermo-magnetic generators, or motors, and we are now enabled to describe another form designed by Mr. Nikola Tesla, who, it is interesting to note, obtained the first patent for a thermo-magnetic motor in the United States. The machine here described embodies several novel features of construction, which constitute a marked departure from the forms hertofore shown, and which consist first, in the employment of a closed magnetic circuit and an enclosed source of heat. The advantages gained by this arrangement will be apparent when it is considered that by the employment of a closed magnetic circuit a more effective magnetic change may be obtained and that by enclosing the source of heat and cooling the heated portion of the magnetic circuit the conversion may be rendered far more efficient. Other novel features are the employment of an armature of enormous cooling surface and steam as a cooling medium.

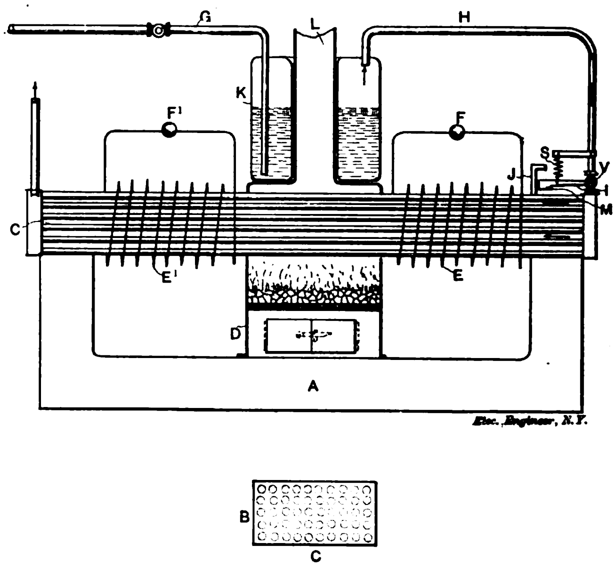
The accompanying engraving Fig. 1 shows a longitudinal section of the generator, and Fig. 2 a cross section of the magnetic armature core employed.

The generator is provided with a magnetized core or permanent magnet A, the poles of which are bridged by an armature core composed of a shell B, enclosing a number of hollow iron tubes G. Around this core are wound the conductors E E, forming the coils in which the currents are developed.

D is a furnace or closed fire box through which the central portion of the core B extends, and above the fire is a boiler K containing water. The latter is supplied by means of the pipe G, and the steam exhaust pipe H communicates with all the tubes C in the armature so that steam escaping from the boiler will pass through these tubes.

In the steam exhaust pipes is a valve V to which is connected the lever I, by the movement of which the valve is opened or closed. The lever carries an armature M, and is held up in position to close the valve V by means of a spring S. Stops are provided for limiting the movement of the lever, and the armature M is in proximity to the core B, so that it may be attracted towards the same, as will be described presently.

In its normal condition the armature B is magnetic along its entire length, and closes the magnetic circuit of the magnet A. Very little external or free magnetism is therefore exhibited, and the attraction upon the armature M is insufficient to draw it down against the force of the spring S. The steam exhaust, in consequence, remains closed. When, by the fire in the furnace, the temperature of the central part of core B has been raised to about from 900° to 1,000° C., the magnetic circuit of magnet A is broken, and, in consequence, the external magnetism of core B greatly increased. This attracts the armature M and allows steam to pass through the tubes C, of the core. This lowers the temperature of the surface of the tubes at once and restores to a corresponding degree their magnetic condition, whereupon the armature M is retracted and the steam cut off.



Elec. Engineer, N.Y.

THE TESLA THERMO-MAGNETIC GENERATOR.

This operation is continued, effecting a successive heating and cooling of the core, with the result of making and breaking the magnetic circuit. This entails a corresponding movement of the magnetic lines with reference to the coils E E, in consequence of which currents are developed in them.

It will be noted that by the construction adopted the source of heat is enclosed and the portions of the iron which are heated are not exposed to the air. The armature which closes the magnetic circuit is made of very thin tubes or laminae and by this means an enormous cooling surface can be obtained.

Steam is used for cooling in preference to air, partly because it is easier obtainable under pressure than air, and again, because it is more effective in consequence of its

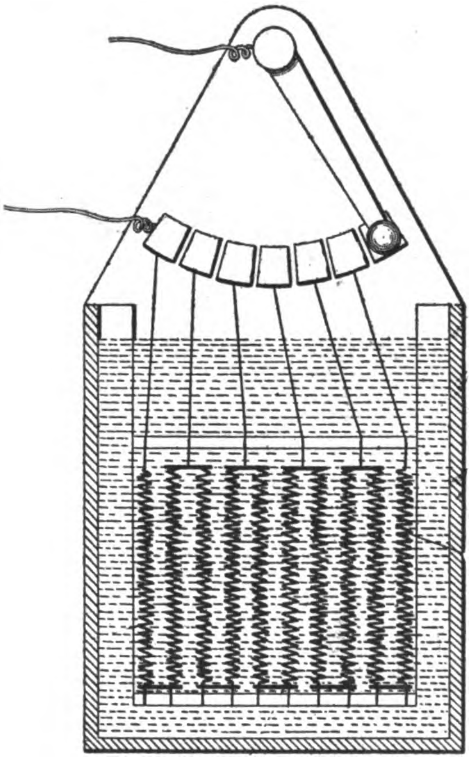
partial dissociation for which a large amount of heat is required.

Although the thermo-magnetic conversion itself may not be highly efficient, yet, since the steam used for cooling may be used for other purposes the system may be rendered economical under certain conditions.

BAIN'S IMPROVED RHEOSTAT.

The employment of rheostats is so frequent in electrical work, and their functions so important, that any improvement in this direction is worthy of notice. We therefore bring to the attention of our readers a neat adaptation for this purpose, by Mr. Forée Bain, of Chicago, by means of which, considerable economy in the cost of rheostats can be effected, especially those designed for heavy currents, and possessing also a number of other advantages.

The arrangement, which is a very simple one, is illustrated in the accompanying engraving, and consists in merely immersing the conductor in a liquid which is itself a non-conductor, but which has a great cooling effect upon the wire.



BAIN'S NEW RHEOSTAT.

As an example of this, Mr. Bain states that a No. 20 iron wire submerged in a vat containing water is capable of carrying for an unlimited time a current of 115 amperes, and while, of course, the water decreases the resistance of the coils, it is found that this decrease is very small, being practically not over two per cent.. while the carrying capacity of the resistance medium is increased many times, as shown.

Besides the saving in wire and smaller space occupied by the rheostat, the danger from fire by overheating is prevented, as, evidently, the wire cannot be heated beyond the boiling point of the liquid in which it is immersed.

....WHEN a current of electricity has to pass through two pieces of metal in contact, the first condition is that the surfaces should be clean, and that is precisely the condition which cannot always be fulfilled in a tramway exposed to the weather and overrun by other traffic.—*Gisbert Kapp.*

THE WESTINGHOUSE ALTERNATING CURRENT METER.

AMONG the large number of apparatuses designed to measure electric energy, various forms of watt-meters have been brought out depending in the most cases upon the inter-action of two parts or coils, one of which carries the current and the other is energized at the constant potential of the circuit. Meters of this class have heretofore been adapted for continuous currents only, but recently Mr. George Westinghouse, Jr., has devoted some attention to the problem of applying it to alternating current meters as well.

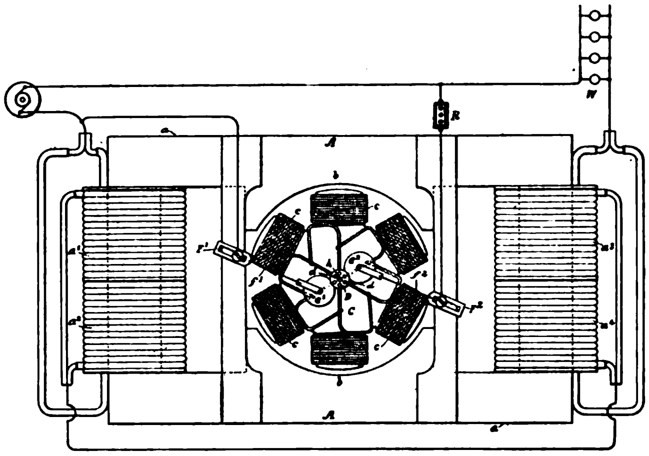


FIG. 1.—THE WESTINGHOUSE ALTERNATING CURRENT METER.

The results obtained by him are embodied in the meter illustrated in two views in the accompanying engravings. In these the field magnets of the motor portion of the meter consist of a soft iron laminated core a having consequent poles at b. The coils a^1 a^2 a^3 a^4 are wound about the core at its respective ends in four divisions, which may be connected in the work-circuit conductor either in series or in multiple, or in multiple series, to suit the requirements of the different circuits. The armature C consists of a polar magnet having a core composed of laminæ of soft iron and wound with the coil c, the terminals of which are connected with the commutator D. Electrical connection is made with the plates of the commutator by means of wheel contacts e^1 e^2 carried upon the spring-arms f^1 f^2, and electrical connection is made with the supports F^1 F^2 of these arms for connecting the armature in shunt upon the work-circuit W.

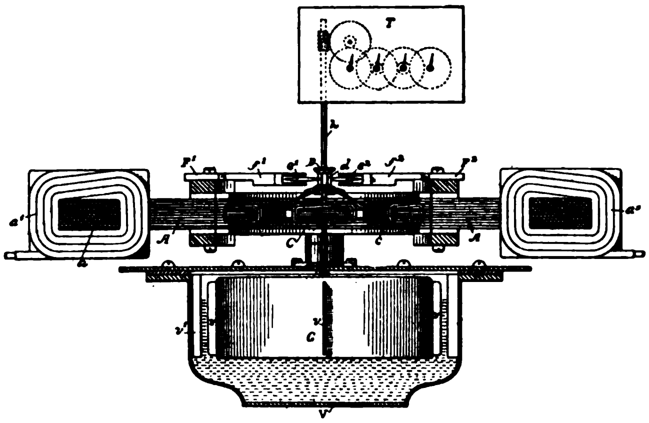

FIG. 2.—THE WESTINGHOUSE ALTERNATING CURRENT METER.

The armature is mounted upon the shaft h which is stepped in a float G; the latter is carried in a basin V containing a fluid, the float turning with the shaft. The revolutions of the armature are registered by means of a counting-train T.

For the purpose of retarding the motion of the armature and rendering its rate of revolution proportional to the work being done at different velocities, vanes are carried by the float G, and these revolve in the fluid which is contained in the basin.

With this construction, according to Mr. Westinghouse, upon a constant potential circuit the armature will receive a constant polarization, while the field of force will vary as the current. Therefore the retarding influence should vary directly as the speed. The result is sufficiently approximated for practical purposes by the use of the vanes and float.

TESTS ON THE FUSING POINT OF FUSE WIRES.

In the following we give the results of certain tests made on fuse wires in the Laboratory of the Massachusetts Electrical Engineering Co. They were made at the request of the engineering department of the company, in order to determine more positive data than was known regarding the actual fusing points under varying conditions of use of such wires.

The method of conducting these tests was as follows :— Fuse wires of various grades and makes were bought from the most reliable dealers. By a conveniently arranged switch, ammeter and adjustable resistance, any current up to 200 amperes could be passed through the piece of wire under test for a given length of time. The current could either be gradually increased through the fuse wire or be adjusted to any strength, and then suddenly passed through it.

The following table is made up from averages of a number of the tests made on smaller sizes of wire :—

Nominal amp. or safe carrying capacity.	Fusing point in less than 10 seconds. 1 inch long.	Fusing point in 30 seconds. 1 inch long.	Fusing point in 10 seconds 2 inches long.	Fusing point in 10 sec. in closed box. 2 inches long.
2.	7.0	6.0	6.6	6.6
2.5	7.8	6.2	7.3	7.2
3.	12.0	9.2	10.0	9.8
3.5	12.5	10.0	10.6	10.2
4.	13.0	11.0	11.0	10.7
6.	14.7	13.8	13.5	12.1
7.	15.3	14.5	13.2	12.9
8.	18.0	16.5	14.0	13.5
10.	20.0	18.7	18.0	17.6
15.	36.0	34.0	28.0	27.0
20.	53.0	47.5	45.0	43.5

A similar series of tests were made on several makes of wires, and the following conclusions reached :—

A longer piece of wire will fuse with less current than a shorter. This is due to the less rapid conduction of heat from the centre of the fuse wire into the binding posts and main wires.

The fusing point in a closed box is lower than that in the open air, the difference varying with the conditions in each case and due to the more or less rapid radiation of heat from the wire.

The fusing point varies with the temperature of the air surrounding the wire.

The fusing point varies with the length of time the current flows; that is, it will fuse at a lower point if the current flows for a longer time.

The requirements for a good fuse wire are :—

(1) The nearest approach possible of the fusing point to the safe carrying capacity.

(2) A constancy under varying conditions of position and temperature.

(3) Rapidity of fusing at the proper current.

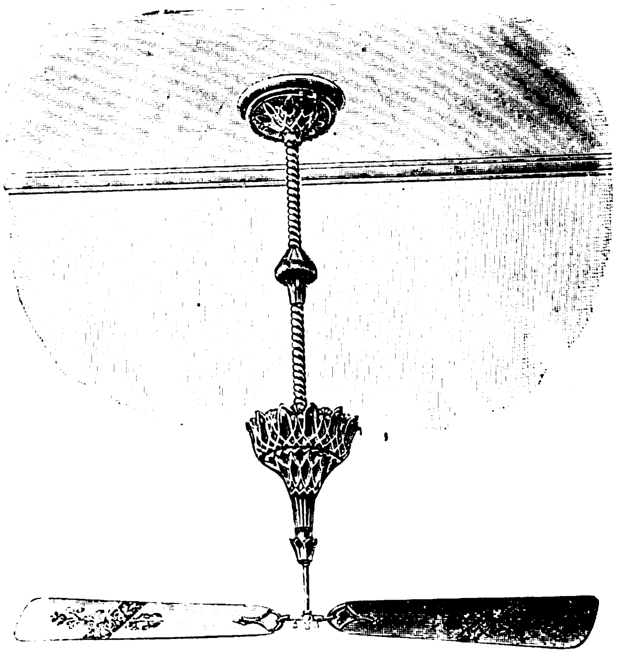
(4) It should not throw the particles of molten metal or "splutter," thus endangering the surroundings from fire.

The best wires tested had a fusing point in enclosed space for the smallest sizes, of about 200 per cent. above their safe carrying capacity, of the medium sizes of about 100 per cent. and the largest sizes of about 50 per cent., and less, above their safe carrying capacity. These tests and experiments are being carried still further in this laboratory with a view of devising, if possible, some better system of fuses.

THE DIEHL SUSPENDED MOTOR FAN.

As the heated term approaches, the subject of ventilation in buildings takes a prominent position, and as in everything else at the present time requiring the application of small units of power applied at numerous points, the electric motor is called upon to furnish the required energy. The small motor is eminently adapted for this service, and finds in this field an application which has already involved the employment of thousands of such machines. Mr. Philip Diehl, of Elizabeth, N. J., has given considerable attention to this subject and has designed a suspended motor fan which embodies a number of features that make it eminently adapted for the particular purpose for which it is designed.

The fan is illustrated in the accompanying engraving and will be seen to consist of a small continuous current motor, which is practically hidden in the metal basket shown, and to the armature shaft of which are attached two fan blades. The small motor is usually wound for 110 volt circuits and revolves at 200 revolutions, a low speed and one calculated to revolve the five-foot fan blades with most effective results. A rheostat, which can be placed in circuit, varies the speed as desired, however.

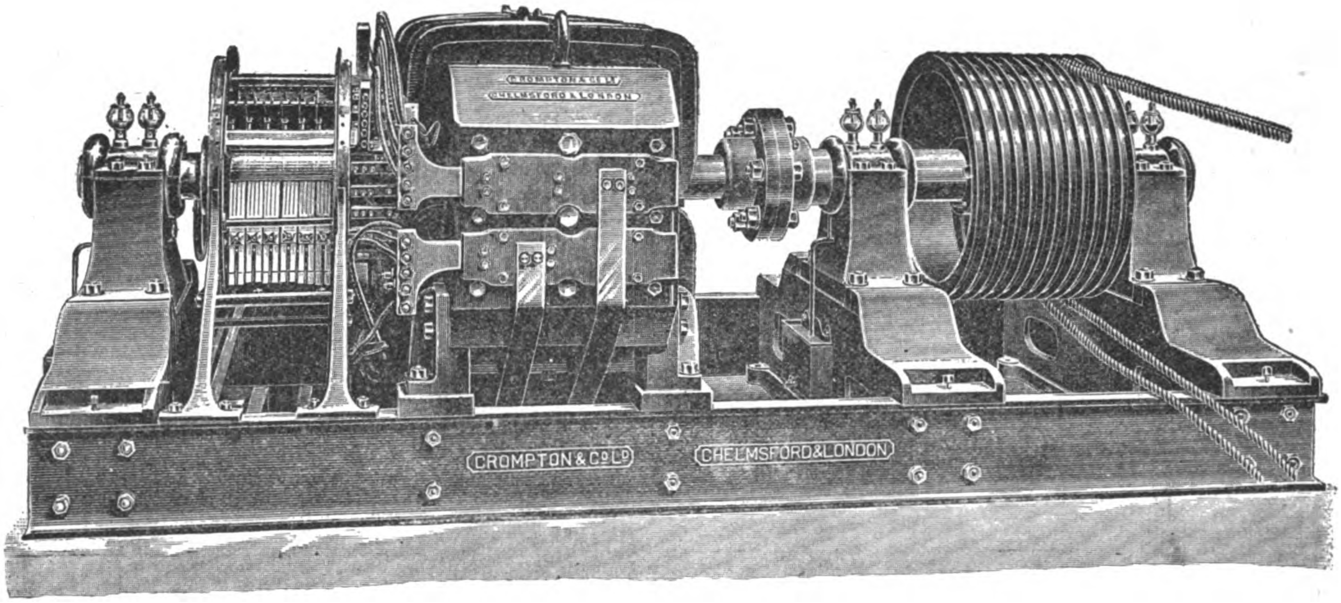


The Diehl Suspended Motor Fan.

The construction of the small motor embodies a Gramme ring which revolves outside of the field magnet. The latter is made of drop-forged wrought iron, and is made in one piece and wound continuously. The armature ring has a core of soft iron wire, and the winding of both field and armature is effected automatically, the winding of the armature being accomplished by a special machine of most ingenious construction. The armature runs on hardened steel ball bearings placed in a cup-shaped ring, which is filled with lubricant and which permits the motor to be run a long time without any attention whatever. On account of the slow speed employed, the commutator and brushes wear very little, a result that is also brought about by the use of Tobin bronze for the commutator sections.

The motor and fan are suspended by a rod, which can be varied in length so that the blades can be placed at any height from the ceiling. This, however, can be done independently of the motor and fan blades, which form one integral part, the suspension rod being entirely independent. The wires leading to the motor are concealed in the extension rod and the whole is suspended on a hook by the employment of which the fan and motor seek their true center of gravity and thus prevent all disturbing vibration. Besides this type of fan, Messrs. Diehl & Co., of Elizabeth, N. J., manufacture various other types and also their well-known sewing machine motors, as well as motors for all stationary purposes. All these machines are constructed with interchangeable parts, and are built at the well-known Singer Sewing Machine Works, renowned for the accuracy and quality of their output.

CROMPTON FOUR-POLE DRUM DYNAMO.[1]



New Crompton Four-Pole Dynamo.

The above illustration shows a new four-pole drum machine made by Messrs. Crompton & Co.,Ld., Chelmsford. We feel confident, says *Industries*, that the single magnet two-pole drum dynamo now in almost universal use will give way to the four-pole type for sizes above 200 watts per revolution. The four-pole machine seems to have everything in its favor. The end couplings, which are the most troublesome part of two-pole machines, are beautifully simple when four poles are used, as the connections are only a quarter round the armature, and do not tend to foul the spindle or to block up ventilation spaces. Besides this, they are infinitely more accessible, a point of great importance with reference to repairs. If a four-pole machine has the same number of active conductors, the loss by hysteresis in the armature is approximately the same as in a two-pole machine, for, though the iron is reversed twice as often, there is only about half the volume ; or if, on the other hand, the radial depth is kept as before, the induction is very much lower. For large currents the four-pole drum is especially suitable, as the current in each conductor is one-fourth of the whole current, and the commutator sections are more numerous than in the corresponding two-pole machine.

The machine we illustrate has an output of 50 volts and 2,500 amperes at 400 revolutions per minute. The armature has 48 external conductors of 185 strands of No. 16 B.W.G. twisted and compressed into a rectangular cross section. The armature diameter is 22 in. It is built of discs keyed to a soft steel spindle. The spindle is made in two parts, coupled by a cast-iron coupling, and fitted with a pulley for rope driving. There are three bearings, and these have only the bottom brasses lined with white metal. The magnets are wound with 13 layers of copper strip 0.19 in. by 0.24 in., resistance cold 0.9 ohm, all in series. The magnets are 26 in. by 11½ in. There are four sets of six brushes each. The opposite brushes are coupled together in parallel. Each brush is 2 in. wide. The machine is mounted on a bed-plate built up of two channel girders of wrought-iron, to which the pedestals of the magnets and the bearings are bolted.

One of the chief advances in this machine is the engineering design of the armature conductors. These have faced joints, and are screwed together with steel bolts and nuts. So perfect is this system, and so simple are the end connections, that the whole armature can be stripped in four hours, and put together in a somewhat longer time, including new bands. A repair, if ever necessary, could be executed in a very short time, unless, of course, the bands had to be taken off. This dynamo is for smelting work, a branch of electric business in which, as is well known, Messrs. Crompton have been particularly successful.

Two large dynamos, each capable of delivering several thousand amperes of current, are already in operation at the works of the Aluminium Smelting Syndicate at Milton, near Stoke-on-Trent, England. They are there employed in the reduction of aluminates, such as corundum, according to Cowles process as practiced at the Cowles works at Lockport, N. Y., where, as will be remembered, several large Brush machines which furnish the current for the reduction, are driven by water power.

THE CARTWRIGHT ELECTRICAL PROTECTOR.

With the increasing number of wires carrying heavy currents run in close proximity to others connected to instruments requiring but very small currents for their operation such as telephones, fire and police signal apparatus, etc., it becomes desirable to employ some device to prevent the destruction of the latter instruments by burnouts, which may be caused by the crossing of the wires carrying the heavy and light currents, respectively. As the recent large fire in Boston is by some ascribed to an accident of this nature,notwithstanding the report of a great many respects to the contrary, interest has been aroused in that city in devices for the protection of circuits designed to carry light currents and among them the Cartwright

---

[1] *Industries.*

"electrical protector," has attracted considerable attention. This instrument is shown in perspective in Fig. 1, and Fig. 2 is a diagram of the electrical connections.

As will be seen, the iron core, A, is supported on two angle irons, B, attached to the base plate, and which are in connection with the ground terminal, G. Two helices, separated from each other in the middle by a rubber washer, and made of coarse wire, are wound on the core, their inside ends being connected through the terminals, F F, to the line, and the outside ends through the armature lever, H, through terminals on the other side of the instrument to the apparatus to be protected.

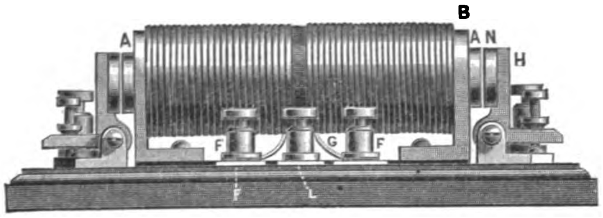


Fig. 1.—Cartwright Protector.

The armature lever is so adjusted by weight or by springs that the normal current has not sufficient strength to attract it, but as soon as an abnormal current comes in over the line the armatures are attracted to the core, and the current is shunted to the ground, the telephone or other instrument being cut out. Another form of this instrument is illustrated in outline in Fig. 3. In this form, which is employed at terminal stations, a single helix is used. It is composed of an ordinary electro-magnet, whose armature-lever, H, is provided with a metallic spring, c, which, when the armature is attracted, makes contact with a contact-point, *d*, connected with the line if at an intermediate station, and at the ground if at a terminal station. One terminal of the instrument to be protected, such as a telephone, is connected to this contact-point, and the other terminal of the telephone is connected through the armature to one end of the coil of the electro-magnet. The other end of the coil of the electro-magnet is connected to the line, and the core of the electro-magnet is connected to the earth.

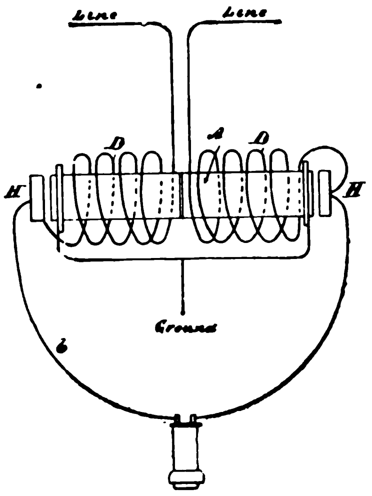

Fig. 2.—The Cartwright Protector.

When the current is normal the instrument to be protected is in the circuit; but when a current of abnormal strength comes on the line the armature lever is attracted, and the spring, *c*, makes contact with the contact-point, *d*, thus cutting out the telephone and connecting the line to ground through the armature and the core of the electro-magnet.

An important feature of the apparatus is that it not only protects the instruments and circuit, but enables the ringing in of an alarm from any point, on a fire-alarm circuit for instance, even when the outside wires are crossed by an abnormal current. This is effected by a combination of the protectors and fuses, so arranged as to temporarily cut out the deranged or crossed wire between any two boxes, and to substitute a ground to complete the circuit between these boxes.

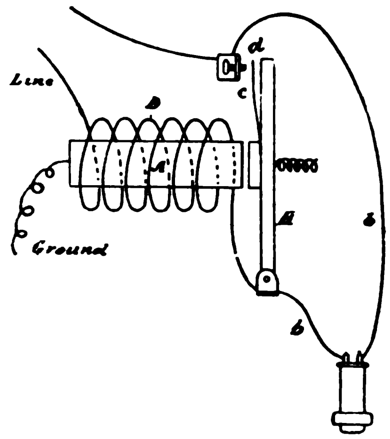

Fig. 3.—The Cartwright Protector.

ON THE SHAPE OF MOVABLE COILS USED IN ELECTRICAL MEASURING INSTRUMENTS.

In a note presented to the London Physical Society on the above subject Mr. J. Mather seeks to determine the best shape of the horizontal section of swinging coils such as are used in D'Arsonval galvanometers, electro-dynamometers, wattmeters, etc. Assuming constant period and constant moment of inertia about the axis of rotation, it is shown that for zero instruments the best shape of the section is two circles tangential to the direction of the deflecting field at the point about which the coil turns. A table accompanies the paper, in which various forms of section are given, together with their relative deflecting moments per unit moment of inertia; the coils being taken of equal lengths and the current density being constant. From this table it appears that ordinary D'Arsonval coils only give about 45 per cent. of the maximum deflecting moment, and ordinary Siemens' dynamometers from 40 to 53 per cent. The various assumptions made in the paper are shown to be justifiable in commercial instruments, and the modifications necessary in special cases are pointed out.

Mr. C. V. Boys said he had, when working at his radio-micrometer, arrived at a shape similar to that recommended in the paper. He also noticed a peculiar relation time for all shapes where the length parallel to the axis of rotation is great compared with the breadth. Suppose a coil of any dimensions, then another coil of half the breadth and double the length, and cross-section, will be dynamically, electrically and magnetically the same as the original, for the moment of inertia, the electric resistance, and the enclosed magnetic field are equal. The above relation is also true when the breadth is not small, if the cross-pieces be thickened near the axis so as to make their moment of inertia proportional to their length. He inquired whether the author had considered the subject of grading movable coils; he, himself, was of opinion that, unlike fixed galvanometer coils, the wire near the axis should be thicker than that further away.

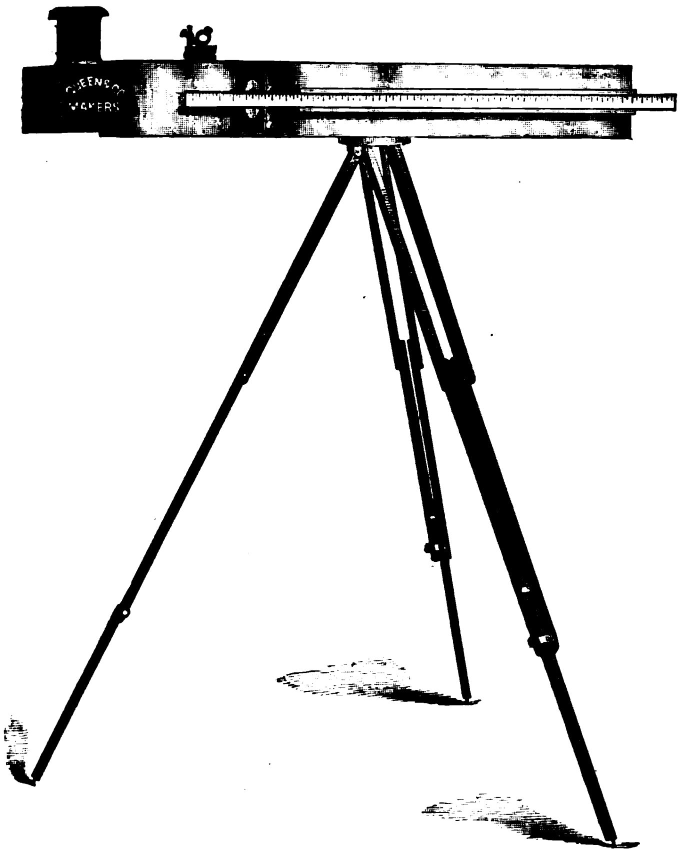
Prof. Ayrton remarked that in 1881 Prof. Perry and himself exhibited a wattmeter at the Society of Arts, whose movable coil somewhat resembled one of those in the paper which gave a deflecting moment of 95 per cent. of the maximum. In designing the instrument they had felt that the ordinary method of using a comparatively large swinging coil was not the best, and this led them to the shape adopted.

....A simple calculation shows that with bearings perfectly in line, and good lubrication, a wrought iron shaft of uniform thickness and two miles in length, cannot be turned from one end because the resistance of friction is greater than the torsional moment which can safely be applied.—*Gisbert Kapp.*

NEW PORTABLE PHOTOMETER.

To meet the demand created by the rapid adoption of the electric light for town and city lighting, and the consequent necessity of making frequent tests for the purpose of conforming to certain standard conditions, Messrs. James W. Queen & Co., of Philadelphia, have recently brought out a new form of Bunsen's photometer. The instrument is made very compact, being designed especially for street work by government inspectors and experts having occasion to make candle power tests of arc and incandescent lamps.

The apparatus, which is illustrated in the accompanying engraving, is mounted on a tripod, and is 5¼ inches square in cross section and 38 inches long, and made of polished cherry. The lantern, as shown, slips into one end of the box, where it is firmly held; a small adjustable holder carries the standard light, which may be either one or two standard candles. This adjustment regulates the height at which the flame stands, and also its distance from the screen; by making the latter distance exactly one foot, computation is greatly facilitated. Distances are measured by a graduated bar shown, which slides in grooves along the side of the box.



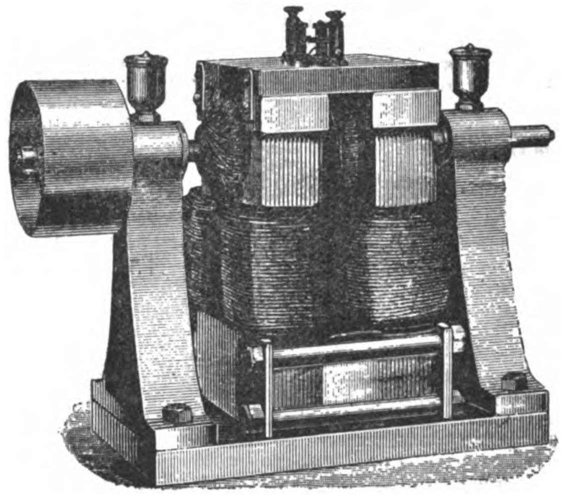
New Portable Photometer.

To allow for the difference in vision between the right and the left eye, the instrument is made reversible, that is, it may be turned completely over so that the right eye observes the side of the disc before observed by the left, and vice versa. When not in use the lantern chimney slips out and can be placed inside the lantern itself, after which the entire lantern box may be pushed inside the photometer, and small slides made to cover the two ends and the sight hole of the instrument, making a solid box of it. A brass handle on one side allows the instrument to be carried as easily as a small hand bag. A small incandescent lamp can, of course, be used as a standard instead of candles. The range of the instrument is from about four candle power up, and it has already been very successfully used in several tests involving expert opinion.

KENNEDY'S ALTERNATING MOTOR.[1]

The accompanying engraving represents Mr. Rankin Kennedy's new alternating electric motor. It consists of two ordinary dynamos, with ring or drum armatures (drum armatures being shown in the engraving), and laminated field magnets; both armatures are on the same shaft, their coils being connected together. One of the machines acts as the motor, the other taking the place of the commutor; there are no brushes and no commutator, and, therefore, one gets an entire absence of sparking.

The motor requires two currents, one at a quarter of a complete alternation in advance of the other; but it does not require any synchronising, and it can start with load on from rest. The two currents at different phases are obtained from a transformer or two line wires with a third for a common return, or from a coil wound on the field of one of the combined machines. Larger machines are made multipolar.



Kennedy's Alternating Current Motor.

SOLAR ACTION ON ELECTRIC CHARGES.

MM. T. Elster and H. Geitel have found that pieces of polished metal do not preserve a negative charge of electricity after being exposed to the rays of the sun, or even to the light of day. The positive charge, on the other hand, can be quite well preserved. In a dim light both charges can be kept, and this effect is more sensible for magnesium and aluminium than for zinc. Plates of polished metal exposed to the sun's rays are charged positively. A film of water, or even of mist, on the surface is quite enough to prevent these actions almost entirely.

THE RESISTANCE OF CONDUCTORS TO TRANSIENT CURRENTS.

At a recent meeting of the Royal Society of Edinburgh, Sir William Thomson read a paper recounting an accidental illustration of the effective ohmic resistance to a transient electric current through a steel bar. He said that at the recent meeting of the British Association at Newcastle, Lord Armstrong had told him of an interesting incident. A bar of steel about a foot long, which he (Lord Armstrong) was holding in his hands, was allowed accidentally to come in contact with the two terminals of a dynamo. He instantly felt a painful sensation of burning, and he let the bar drop. He found his fingers where they had been in contact with the bar severely blistered. The bar was found immediately afterwards to be quite cold. This proved the outer surface of the steel to have been intensely heated, and that not enough of heat was generated to sensibly warm the whole bar. Lord Armstrong had sent him the bar and some further details. There were two hollows burned out of the metal at the points where the bar touched the terminals of the dynamo. Lord Armstrong had held the bar midway between the two marks. It was perfectly cold three or four seconds after he dropped it. The dynamo gave an alternate current of 85 amperes, at a difference of potential of 103 volts. Sir William Thomson then showed how the theory involved could be worked out by Maxwell's fundamental equations of electro-magnetism. He discussed the theory at some length, and showed that there was a thermal analogy.

THE ELECTRICAL EXHIBITS AT THE PARIS EXPOSITION.[1]

BY CARL HERING.

BARE AND INSULATED WIRES AND CABLES.

GENERAL.

THE bare wire exhibits were confined almost entirely to the French section, and were in general very creditable, showing fineness of work and results of considerable, and apparently successful, research to obtain a mechanically strong wire of high conductivity for line wire. High insulation, water-proof wires were equally well exhibited by France and the United States; in the former the insulation used was almost entirely of soft rubber and gutta-percha while in the latter it was principally paraffine and rubber compounds. The cable exhibits were confined to a few large, well-known companies from France and England. The cable industry in France has developed almost entirely during the last 10 or 15 years, before which time their cables were made almost entirely in England. There were a few insulated wire exhibits from Russia, Japan and elsewhere, but without particular interest.

HISTORICAL.

Among the historical exhibits was a sample of an underground wire laid between Baltimore and Washington in 1844. It consisted simply of a copper wire, about No. 18 B. & S. gauge, covered with an insulating compound and enclosed in a lead tube. It was exhibited by the Western Electric Co.[2]

BARE WIRES.

The exhibit of bare wires of the firm of J. O. **MOUCHEL** (French section, Gold medal), was undoubtedly the finest of its kind and was particularly interesting on account of the fineness and regularity of their goods, as also on account of the very elaborate researches made by them with different alloys, to obtain great tensile strength combined with good conductivity for line wires, and to obtain great resistance with small temperature co-efficient, for resistance coils.

These are probably the oldest wire manufacturers in France, dating as far back as 1709. They employ at present 200 hands (of whom 120 have been there more than 10 years!) and 450 h. p. Their specialty is fine, delicate work, purity of alloys, length of pieces and regularity of diameter.

The following table gives the results of their elaborate experiments made in 1884 to study the effects of small quantities of foreign metals alloyed with copper:

Wires 0.50 mm. diameter, annealed. Alloys of pure copper with 1 part of the following metals (pure) in 1,000.	Resistance per kilometre in legal ohms at 0° C.	Conductivity.	Elongation.	Ultimate tensile strength in kilogrammes per sq. millimetre.
Lead	78.21	104.04	36.20	19.09
Molybdenum	78.78	103.28	33.50	21.90
Cobalt	79.17	102.77	38.15	20.62
Silver	79.30	102.60	4.25	29.02
Sulphur	79.31	102.59	37.55	21.51
Gold	79.35	102.54	33.45	20.62
Selenium	79.43	102.44	30.42	27.23
Thallium	79.44	102.42	36.10	21.26
Zinc	79.59	102.22	35.32	27.06
Antimony	81.30	100.08	300.0	22.91
Tellurium	81.50	99.84	1.82	41.35
Platinum	81.98	99.25	38.80	20.37
Nickel	82.72	98.37	39.00	20.88
Tungsten	84.08	96.77	36.35	21.51
Tin	84.49	96.31	3.65	32.42
Chromium	85.64	95.01	33.55	22.92
Magnesium	86.29	94.29	3.75	36.54
Aluminium	89.86	90.55	35.20	22.15
Magnesium	90.09	90.31	33.75	27.57
Iron	97.65	83.32	32.65	22.05
Arsenic	105.17	77.36	39.10	21.77
Silicon	120.44	67.55	20.65	18.33
Phosphorus	149.84	54.30	31.25	23.42
Bismuth Cadmium Potassium Sodium	Unman	ageable	....	....

The different effects of different proportions are seen in the two following striking examples: $\frac{1}{10}$ of one per cent. of phosphorus reduces the conductivity of copper to 54.30 %, while 5¼ % reduces it only to 10.079 %. With arsenic $\frac{1}{10}$ of one per cent. reduces copper to 77.96 %, while 5 % reduces it to 5.72 %.

They exhibited also a pure copper wire, the conductivity of which is 104.69 % deduced from measurements which were controlled at the Vienna Exposition and certified to by Messrs. Blavier, Stefan and Discher. The high conductivity of copper, which is doubtless correct, simply shows that the generally accepted value for pure copper is too low. Next to this exhibit of remarkably high conductivity there was shown, by way of contrast, a similar wire of .50 mm. of remarkably high resistance, made of an alloy of copper and arsenic, having a resistance of 2,335.50 ohms per kilometre, which is equivalent to a conductivity of 3.48 % or about double the resistance of German silver.

Their regular copper telegraph wire, annealed, has a conductivity of 102.5 %, an elongation of 35 to 38 %, and a breaking strain of 20 to 25 kilogrammes per sq. mm. (28,000 to 35,000 lbs. per sq. inch), depending on the degree of annealing. The co-efficient of temperature is .40 % per degree centigrade.

Their two principal bronzes have 98.5 % with 45 kilogr. (64,000 lbs. per sq. in.), and 34.6 % with 75 to 90 kilogr. (107,000 to 128,000 lbs. per sq. in.), as conductivity and breaking strain respectively. These can be wound around a wire of their own diameter without showing any breaks. The former will stand 20 bendings in a vise, and the latter 30 to 35.

Their experiments with magnesium have given very interesting results, showing great strength combined with good conductivity. The following figures show some of the results:

Tests With Magnesium-Copper Wires.

Conductivity.	Breaking strain.
95.16 per cent.	51.80 kilogr. per sq. mm.
81.60 "	61.09 " "
63.89 "	75.17 " "
58.01 "	81.37 " "
51.43 "	95.49 " "
50.61 "	76.47 " "

They find it impracticable to go below 50 % conductivity, or above 70 kilogr. breaking strain. For exceptionally great spans of line wire they have arrived at 100 to 110 kilogr. with a conductivity of 21 %. These figures are nearly the same as those of the silicium bronze wire exhibited by Weiller, described below.

Their German silver resistance wire has a conductivity of 7.35 to 4.40 %. They find that while all known alloys increase in conductivity on being annealed, the German silver will decrease when the proportion of nickel is greater than 10 %.

Their new high resistance arsenic alloy containing 10 % of arsenic, has a conductivity of only $3\frac{1}{3}$ % and a temperature co-efficient of only .0258 % per degree centigrade (that of German silver being .0393 %). This alloy is very difficult to work, but in spite of this they exhibited it drawn to the remarkably small diameter of 17 thousandth of a millimetre, or .00067 inch, or about $\frac{1}{10}$ as fine as No. 34 American gauge! The resistance of this wire is 2,052 ohms per metre!

Another curiosity which they have made is a coil of telegraph wire in a single piece (without any joints) weighing 660 pounds. This was before electric welding came into use.

LAZARE, WEILLER & CIE., (French section, Gold medal) had a fine exhibit of bare wire, chiefly of their patent Silicium Bronze, which appears to be their specialty. They claim as advantages for this line wire, over the usual iron or steel wire, that for the same conductivity the weight per mile is several times as small; that, therefore, it is much easier to run; that it diminishes the dimensions and number of poles and insulators; and, that owing to its increased strength, there is less danger to rupture from wind and snow; also, that it is absolutely inoxydizable.

The following figures, taken from their tables, show the most important properties. For long telegraph lines a silicium bronze telegraph wire of 2 mm. diameter (.079 inch, or about No. 12, B. & S. gauge) weighing 28 kilogr. per kilometre (100 lbs. per mile) has the same resistance as, and can replace, the usual galvanized iron wire 5 mm. in diameter (.197 inch, or about No. 4, B. & S. gauge) weighing 155 kilogr. per kilometre (550 lbs. per mile) and having a resistance of 5.40 ohms per kilometre (8.7 ohms per mile.) For telephone lines, a silicium bronze wire of 1.1 mm. diameter (.043 inch, or about No. 17, B. & S.) weighing 8.45 kilogr. per kilometre (300 lbs. per mile) has the same resistance, and can replace a steel wire of 2 mm. diameter (.079 inch, or about No. 12, B. & S. gauge) weighing 25 kilogr. per kilometre (89 lbs. per mile) and having a resistance of 40 ohms per kilometre (64 lbs. per mile.)

The conductivity and the tensile strength may be varied at pleasure, for different purposes; as one quality increases, the other diminishes. The following figures, showing the properties, are taken from their tables:

---

[1] Advance sheets of the report of the expert of the U. S. Commission to the Paris Exposition, Section "Electricity."

[2] See also description of exhibits of Henley and Menier, below.

Size of silicium bronze wire 1.5 mm. or .059 inch, or No. 15 B. & S. Gauge.	For long distance telegraph lines.	For long span telegraph lines.	For telephone lines.	For telephone lines, new type.	For telephone lines, for long spans.

Resistance in ohms per mile..............	15.2	18.4	46.4	35.0	70.0
Conductivity per cent. as compared with copper (having 20.57 ohms per kilometre per 1 mm. diam.)..........	97.	80.	32.	42.	20.

Charles Martin & Cie., (French section, Bronze medal) exhibited a line wire called "bi-metallic," consisting of a core of steel, and a thick, solid layer of copper around it and united to it. The proportions of copper and steel are about half and half. It is made not only for telegraph and telephone lines, but also for the transmission of power and light, as well as for electric bell circuits. Pure copper wire would be best for lines if it were not for the high price, and the fact that it is so soft that it is apt to tear when in long spans, or to elongate by its own weight, thereby diminishing its cross section and increasing its resistance. The object of this bi-metallic wire is to combine great tensile strength with good conductivity, small weight and cheapness. The advantages claimed over the phosphor and silicium bronze wires are, that the latter are brittle, and will not stand bending or twisting, and, that in course of time, they become granular or crystalline, and that they are expensive. The object of the bi-metallic wire is to combine the good conductivity of copper with the tensile strength of steel, and at the same time use the copper sheath to protect the steel from the action of the air and water. The process is not described, being apparently a secret. The two metals are firmly united, as though they were welded. The weight and diameter are evidently less than that of a steel wire of the same conductivity would be, and it is claimed to resist a greater tensile stress than copper wire. It is claimed to resist perfectly bending and torsion, and that it is quite flexible and elastic. The selling price for 1 mm. diameter and over is given as 150 francs per 100 kilogrammes, which is equal to about 13 cents per pound.

There is a disadvantage in its use, however, namely, that if the steel should be exposed anywhere, the action of moisture will be to destroy the steel at that place much more rapidly than if it were not covered with copper, because the steel and copper form a short-circuited electric couple the action of which is to decompose the iron and to clean the copper. In galvanized iron wire this electrical and chemical action is just the reverse, as it keeps the iron clean at the expense of the zinc.

Copper-covered iron wire was made in the United States more than a dozen years ago, and for the same object. It was made by electro-plating the iron wire with a thick coating of copper. But it was found that the iron wire appeared to absorb in its pores some of the liquid of the bath, which in time destroyed the iron completely by the action described above. All the lines run had to be replaced, and the extensive wire works had to be abandoned. It is presumed, therefore, that the process of Martin is not the same. In one specimen the steel was 1⅛ inch in diameter, and the copper ⅜ inch thick.

The following figures give the results of some tests of the Martin bi-metallic wire. They were made at the Laboratoire Centrale d' Electricité of the Société Internationale des Electriciens:

External diameter, 3 mm., or between Nos. 8 and 9, B. & S. gauge.

Ultimate tensile strength, 388 kilogr., or 55 kilogr. per sq. mm.; or 78,000 lbs. per sq. inch. (That of copper is about 26 kilogr. per sq. mm.; or 37,000 lbs. per sq. inch.)

Elongation, 28 per cent.

Number of times it could be bent through a right angle alternately in opposite directions when held in a vise, 20 to 24.

Resistance per kilometre at 14° C., 3.91 ohms, or 6.3 ohms per mile. (That of a copper wire of the same diameter is 2.35 ohms per kilometre, or 3.96 ohms per mile. That of an iron wire of the same diameter is 14.05 ohms per kilometre, or 22.6 ohms per mile.)

From these figures the following deductions may be made:

Its conductivity is 60 per cent. of that of copper, and 360 per cent. of that of iron wire of same diameter.

The size of a copper and iron wire of the same resistance would be 2.33 mm. and 5.7 mm., or about Nos. 11 and 3, B. & S. gauge, respectively.

The weight of the bi-metallic wire is given as 62.5 kilogr. per kilometre, or 222 lbs. per mile.

That of the iron wire would be about 200 kilogr. per kilometre, or 700 lbs. per mile.

For the same weight of wire on the poles, the number of lines of the same resistance could therefore be tripled, as compared with iron wire.

Or, for the same weight as the iron wire, the size of the bi-metallic wire would be 5.4 mm. (between Nos. 3 and 4) and its conductivity increased 3.2 times.

Another test made by the same parties gave the following results:

Diameter, 1.29 mm., or No. 16, B. & S. gauge.

Ultimate breaking tensile strain, 84.5 kilogr., or 65 kilogr. per sq. mm., or 92,000 lbs. per sq. inch.

Number of times it could be bent backward and forward over a bar 10 mm. (.4 inch) diameter, 50 to 60.

Resistance, 19.61 ohms per kilometre, or 31.6 ohms per mile.

Resistance as compared with copper wire of the same diameter, 66 per cent.

INSULATED WIRES.

Fortin-Hermann (French section, Gold medal) exhibited an insulated wire made of a bare copper wire on which are threaded small, short, wooden beads, quite close to one another, the whole being afterwards covered with a lead pipe. It is therefore quite similar to an insulated wire made in the United States some six or eight years ago in which the beads were of porcelain instead of wood; the porcelain had the advantage that the beads could be made large and have numerous holes, so as to contain a number of wires in the same lead pipe and insulated from one another. In the case of the Fortin-Hermann multiple wire cables each wire is first covered with its beads, and these are afterwards bunched and covered with lead, making, however, a rather bulky cable. The claims are that it is cheap, that the insulation is very high, and that the specific inductive capacity of the wooden beads is much less than that of porcelain, and that, therefore, the static capacity is very low, being, for underground wires, even lower than in aerial lines; and as the air enclosed in the lead remains unchanged, the insulation and capacity remain unchanged. It is used largely in Paris for underground telegraph and telephone lines, and has given very good results, particularly for telephone lines. The following data (reduced to miles), was given:

Insulation, per mile..................................	900 to 6,200 megohms.
Conductivity, per mile................................	10.3 to 18.9 ohms.
Capacity, per mile..	.068 to .060 microfarad.

The **Patterson** cables, included in the exhibits of the **Western Electric Co.** (United States section, Gold medal for collective exhibit), were, besides the Okonite exhibit, the only United States exhibit of cables containing many small conductors. They consist of groups of conductors, each covered with two or more windings of cotton or jute, or both, saturated with paraffine and protected by a pipe made of some composition resembling a lead alloy. This composition is said to withstand the action of water and gases underground where lead would be destroyed; it is harder and tougher than lead without being any less flexible. The space between the conductors and the pipe is filled with hot aerated paraffine free from any oil and introduced under pressure together with carbonic acid gas ($C O_2$). The almost invisible globules of gas scattered uniformly through the mass of paraffine render it elastic, so that the natural shrinkage of the paraffine in cooling is compensated for by the expansion of these globules, thus preventing the formation of cracks and longitudinal fissures through which water would penetrate indefinitely in case of a break in the pipe. Any flaw or leaking joint in the pipe is detected by the process of filling under pressure. The core may be made in lengths of 1,500 feet and the pipe in lengths of 80 to 140 feet. Another function of the occluded gas is to diminish the specific inductive capacity of the paraffine; it is claimed to diminish it 15 per cent. below that of pure solid paraffine, and this, they claim, enables them to use smaller conductors than if gutta-percha or rubber were used. This diminished size is claimed to prevent, to a large extent, troubles from "cross talk," due to the condenser action in the neighboring wires.

The current which leaks through the insulation of a cable has a tendency to produce chemical changes if any liquids are present. High insulation, therefore, diminishes this action by reducing the injurious current besides economizing energy. The paraffine used contains no oil which might have traces of acids or alkalies. Their cables vary from one-quarter to two inches in diameter, and contain from one to two hundred conductors in lengths up to eight miles, and are used for telephone, telegraph and electric light service. Some have the conductors twisted in pairs for metallic circuits.

From November, 1881, to June, 1889, they have made cables containing 86,727 miles of conductors, of which 22,313 are underground, and of which 36,927 are for telephone, 681 for telegraph, and 120 for electric lights.

The Okonite Co.'s (United States section, Gold medal) insulated wire is too well known to require description here. No technical data could be obtained from the company. The material, okonite, is reported to be a mixture of india rubber and mineral hydrocarbons. It appears to be placed around the wire in the form of a band with a longitudinal seam and adheres to the wire very tenaciously. An expert test made for the Jury showed an insulation resistance of 6,800 megohms per kilometre at 8° C. (4,200 megohms per mile), and a capacity of 0.36 microfarads per kilometre (0.58 per mile).

The Cobb Vulcanite Wire Co. (United States section, Gold medal,) exhibited electric light wire insulated with a moderately hard, but pliable vulcanized rubber tube, and with, or without, a lead armor. This tube is made of rubber the vulcanization of which is stopped before the rubber becomes as hard as the ordinary hard rubber, thus giving a material, the insulating properties of which are like those of hard rubber, and having the additional property of being pliable, so that it may be bent to a moderately small circle without injury to the insulation. The tubing is first made of soft rubber mixed with sulphur; by means of special machinery a seamless lead pipe is made around this soft tubing. It is then vulcanized under pressure by compressing the air in the tube, after which the stranded copper wire is threaded through lengths of about 200 feet of this tube, by means of a long steel needle, which operation is done quite rapidly by means of special machinery. The insulation is remarkably high, averaging, for a No. 4 or 5 wire cable, between 10,000 and 20,000 megohms per mile, and sometimes even exceeding 30,000. This is probably in part due to the fact that the tube fits the wire loosely and that it is therefore insulated to a great extent by the air between the wire and its insulating tube. This wire has been used in New York and Chicago for underground circuits.

CABLES.

M. Menier (French section, Gold medal,) one of the principal and oldest (founded 1850) French manufacturers, had a very fine exhibit of insulated wires and cables, chiefly of rubber and gutta percha insulation. This firm is one of the principal ones furnishing wires and cables for the French government (Telegraph and War Departments). The factory covers 5 acres of ground, employs 400 men and 1,000 horse power, using about 300 tons of crude rubber and gutta-percha, their business, including rubber goods, amounting to about $800,000 a year.

They exhibited a piece of their river cable laid for the government between Havre and Honfleur (on the opposite sides of the mouth of the Seine) 8½ miles long. It was laid in 1877 and is still in good condition. It consists of 5 wires insulated with gutta-percha, and protected with jute and a double armor of galvanized iron wire.

The underground electric light cables which they have made for Paris and other cities consist of tinned copper covered with three layers of vulcanized rubber, and covered with lead 2½ mm. ($\frac{1}{10}$ inch) thick. They claim to be the inventors of the double concentric cables.

Other creditable exhibits of cables were those of the **India Rubber & Gutta-Percha Co.** (French section, Gold medal), and **Fowler & Co.** (English section, Gold medal).

Henley's Telegraph Works Co. (English section, Silver medal,) exhibited samples of a large number of cables made and laid by them. Some of them were of interest historically. The earliest were: A single conductor cable laid at Ceylon in 1857, 30 miles, weight 66 tons; another in Egypt, in 1857, three wires, 9 miles and 20 tons; another in Tasmania, 1858, 240 miles, weight 408 tons. They were all of the well-known construction, with a galvanized iron wire armor, covered with a protecting compound.

The Commercial Cable Co. of New York, showed a model of a cable in which the armor was made of short iron tubes the ends of which were made so as to fit into one another, the joints being rendered air tight and elastic by means of thick round rubber rings.

MISCELLANEOUS.

Description of the Underground Wires for the City of Paris.—These cables are composed of wires of seven strands twisted together and covered with two layers of gutta-percha alternating with two layers of Chatterton compound. The cables are formed of 3, 5, 7 or 14 of these stranded wires bunched together, spun over with tarred cotton and covered with three layers, the first, of tarred jute, the second, of cotton tape impregnated with Norway pitch, and the third of tarred cotton tape wound in the opposite direction to the preceding layer. The diameter of the wire used is from .5 to .7 mm. (about No. 24 to 21 B. & S. gauge). The seven wires twisted together and covered as described above, are from 3.5 to 5. mm. diameter (equal to .137 to .197 inch). The copper has a conductivity of at least 90 per cent. that of pure copper; the resistance is not greater than 20.57 ohms per kilometre, (equal to 33.0 ohms per mile,) per square millimetre cross section at 0° C. Those most frequently used have the same resistance as iron wire of 4 and 5 mm. (.157 and .197 inch, or about No. 6 and 4 B. & S. gauge) that is, about 16 to 9.7 ohms per mile. For these the insulation is over 370 megohms per mile at 24° C. (75° F.) and the capacity is less than .48 to .40 microfarad.

Some others are covered with lead in place of the three layers of cotton and tape. These are used in the sewers or tunnels, being merely hung on hooks, while those without lead are put into cast iron tubes in trenches.

For long underground lines the cables are made like the preceding and are generally of three conductors of which two correspond to an iron wire of 4 mm. and the other to one of 5 mm. These are placed in cast iron tubes in trenches. Sometimes when there is only one cable it is covered with an armor of iron wire and simply buried.

The Société des Téléphones, Menier, India Rubber & Gutta Percha & Telegraph Works Co. (Paris) all furnish underground wires for the telegraph department of the city of Paris. For electric light underground cables vulcanized rubber is generally used in place of gutta-percha.

Description of the French Submarine Cables.—The conductor of the submarine cables is made of 7 strands of copper wire. This is covered with a layer of Chatterton compound and then with three layers of gutta-percha alternating with two of Chatterton compound. This is covered with two layers of jute wound in opposite directions, over which is then placed the armor of iron wire. For deep sea cables this armor of iron wire is made of small sized wires, while for shore ends it is made of large wires. For deep sea cables the armor is galvanized iron, while for shore ends it is an extra fine quality of iron wire known as "Best-Best"-quality. This armor is covered with three layers of bituminous compounds and two of tarred linen wound spirally around it.

The submarine cables used by France are almost exclusively made by the large English companies, namely, The India Rubber, Gutta-Percha & Telegraph Works Co., the Telegraph Construction & Maintenance Co. and the firm of Siemens Bros.

For "cable laying" see "telegraphy."

Cable Making Machine.—The Administration of Telegraphs of France exhibited a small model of the machines used by them at their factory for making cables. The bundle of insulated wires which are to constitute the cable are drawn slowly through a series of tubes in line with each other. Between the end of each tube and the beginning of the next, a layer of the covering material, be it insulation or armor, is wound around the cable from bobbins secured on a revolving disc concentric with these tubes. As the cable passes through, these coverings are thereby wound around it spirally and in alternately opposite directions. It also passes through tanks containing the liquid coating material and finally through a jet of cold water.

The following extract from the *Specifications for Galvanized Wire* for the French government, 1879 shows the requirements made and the tests to which the wire is subjected: The iron must be reduced and refined entirely with charcoal, and must be free from scale and other faults. It must be galvanized with pure zinc. Wires of 5, 4, 3, and 1 mm. in diameter must be able to stand a tension of 650, 440, 250, and 30 kilogr. respectively, with an elongation of not more than six per cent. It must resist being wound on a cylinder (size not given!) and subjected to a tension of 500, 350, 200, and 22 kilogr. respectively. The wire must resist being secured in a vise and being bent alternately forward and backward through a sharp right angle each way, 3, 4, 5, and 8 times, respectively. It must stand four successive immersions of one minute each in a solution of copper sulphate (one part to five parts of water) without being stained. The three larger sizes must stand being wound over a cylinder one centim. in diameter, and the smaller one over a cylinder of three mm., without detaching the zinc; but the wire will not be held strictly to this test. The wire must be made in France. In the specifications for 1889 the same conditions were imposed with the following additional requirement: The resistance at 0° C. reduced to a wire of one mm. diameter must not be greater than 156 ohms per kilometre (or about 250 ohms per mile for a No. 18 wire).

Testing.—For testing roughly cables and joints during their manufacture, it appears that the so-called plate, or influence machines (Holtz, Wimshurst, Carré, etc.) developing very high tension electricity, are coming into use largely in France. They seem to afford a ready, cheap and effective means to find whether the cable or joint is good or bad, without however enabling the insulation resistance to be measured thereby.

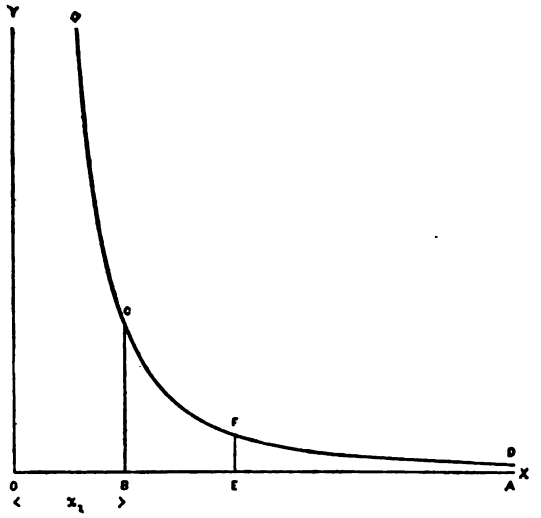
Splices.—**The Western Electric Co.** exhibited some splices of multiple wire Patterson cables, which were said, by some French experts, to be the finest they had seen. One was of 50 pairs, and others of 125 and 100 wires. The individual splices were distributed spirally over a short length of the cable and afterwards covered with a short piece of lead pipe only slightly larger than the other. They exhibited also some good, but somewhat complicated, splices for electric light wire cables.

ON ELECTRIC POTENTIAL AS MEASURED BY WORK.[1]

BY PROF. ALFRED M. MAYER.

The object of this paper is to give a demonstration of the fact that the potential, $V = \frac{Q}{d} = \frac{Q}{r} = \frac{Q}{C}$; when Q = quantity, C = capacity, r = radius in cms. of charged sphere, and d = distance in cms. of centres of two charged spheres.

It occurs to me that this problem could be presented in a direct and clear manner by supposing an electrically charged sphere fixed in space with its centre at O, (see figure), and that another sphere charged with a unit of similar electricity is pushed toward O from an infinite distance, along the line OX, and that the electric strain on the moving sphere causes (without work) a vertical rod to slide out of its top in proportion as the stress between the spheres increases. As the sphere progresses along OX it will thus mark at each point of its progress the repulsive force existing between it and the fixed sphere. The end of the sliding rod during the motion of the sphere from X towards O will have traced out the curve $DFCG$, whose ordinates are as the inverse squares of their distance from O.



Electric Potential as Measured by Work.

Thus we get a trace in a manner similar to that given by the steam-engine indicator, or by one of the many instruments which draw curves, showing the varying effects of pressures, or of stresses.

The potential at any point reached in the progress of the charged body towards O = work done = resistance overcome in pushing body from infinite distance to that point; and this work done is measured by the sum of the resistances at each point of path × the length of path. But this product is equal to the *area* included between the ordinate (say B) of the path, the axis of X and the curve, both indefinitely extended; or, say $CBAD$.

If the body has been moved from an infinite distance up to E, a certain amount of work has been done; and it is to be proved that if the body has been moved from infinite distance up to B, = ½ distance OE, that twice the amount of work has been done. In other words, it is to be proved that area $CBAD$ is twice the area $FEAD$; or, generally, that such areas will vary inversely as the distance of the bounding ordinate (such as FE or CB) from O, the origin of coördinates.

The equation of the curve is

$$y = \frac{a}{x^2}.$$

Area $ABCD$, indefinitely extended =

$$\int_{x_\prime}^{\infty} y\,dx = \int_{x_\prime}^{\infty} \frac{a}{x^2}\,dx = -a\left[\frac{1}{x}\right]_{x_\prime}^{\infty} = 0 + \frac{a}{x}, \therefore \propto \frac{1}{x}.$$

Or, area *indefinitely extended*, which represents the work, is inversely as the distance of y (the bounding ordinate of area) from O, or, $V = \frac{Q}{d}$; but also, $V = \frac{Q}{r}$, and as $V = \frac{Q}{C}$; $r = C$; r being expressed in cms.

I had supposed that the mode of presenting this problem and the demonstration based on that conception as given in this paper, must have ocurred to others before it did to me, but Prof. B. O. Peirce, of Harvard University, who is better versed in the literature of the subject than I am wrote me as follows: "My experience has taught me that students who have not paid much attention to mathematics almost invariably find it difficult to get any true idea of the meaning of the word "potential" and that they value highly anything which helps to make this meaning clearer. Your graphical illustration of the fact that in the case of two electrified spheres the potential function is a measure of work, is new to me and I feel sure that it will prove helpful to persons, who already familiar with indicator diagrams, are struggling to get an idea of the use of the potential function." The opinion of Prof. Peirce determined me to publish this paper.

It should be stated that Maxwell also used the indicator diagram in illustration of an electrical problem, though different from the one here considered. Section 27 of this work. "An Elementary Treatise on Electricity," is thus headed "*Indicator diagram of electric work.* The indicator diagram employed by Watt for measuring the work done by a steam engine, may be made use of in investigating the work done during the charging of a conductor with electricity. . . ."

Stevens Institute of Technology, Hoboken, N. J.

MEETING OF THE NATIONAL BOARD OF FIRE UNDERWRITERS.

The twenty-fourth annual meeting of the National Board of Fire Underwriters was held in this city on May 8, in the Mutual Life Building, president D. A. Heald in the chair.

The Committee on Statistics in their report said, with reference to the efforts made to obtain information from insurance companies as to their experience with certain risks: "An additional class was included in the request, namely, electric-light stations. The Committee was led to make the addition, as the hazard is comparatively new, and it was thought that if the figures in reference to it could be obtained for five years back, we should have practically complete results so far as risks of that character are concerned. The desirability of reliable statistics on the subject was also felt, as the electric light interest had used some satistics at the Niagara Falls Convention which were believed to be very partial, and to that extent, at least, misleading. Blanks were accordingly prepared as to the five classes herein named. Other hazards might as properly have been included, but, as stated last year, the effort was tentative. It was not deemed advisable to ask too much, or to include so many hazards in our blanks as to make it unlikely that companies could spare the clerical force necessary for the work. The Committee regarded its efforts as initiatory to future work, knowing that the field of inquiry could be widened whenever there should be evinced a sufficient interest in the matter to secure results of value to the contributing companies. That interest, however, the Committee has failed to awaken, as would appear from the fact that only twelve companies have responded to the request for the figures for 1889, and but two or three of these, as the Secretary reports, are companies doing an extensive business. In reference to the procurement of statistics of losses it is very much to be regretted that fire-marshal and patrol reports from various cities, are rendered useless as far as affording data of value to the underwriters is concerned, by reason of the absence of any information as to the value of the property directly involved in the loss. It would seem to your Committee that a simple ordinance requiring the Fire-Marshal or other official to obtain that information of every party sustaining a loss would be all that is needed to establish substantial data from which underwriters would be able to arrive at the percentage of destruction in any city."

In their report on lighting, heating, and patents, the Committee said with reference to electric lights and wires: "It did not take many months, however to discover that the electric light was not the harmless thing we had imagined, but that it was a most prolific source of danger, and its introduction has cost the insurance companies more than any method of lighting heretofore in use. It has come to stay, and some time it will probably be as safe as any light in use, but our knowledge of its properties and of its management must be vastly increased before that time appears. We see the danger, but as yet are too ignorant to point out the remedy. What yesterday seemed a safe method of installation to-day proves dangerous, and what we regard as safe to-day is likely to develop danger to-morrow. For a number of years the National Board has followed the action of the New York Board in the matter of rules regulating electric-light equipments. Those rules were revised and re-issued by that Board

---

[1] *The American Journal of Science.*

[Read before the National Academy of Sciences.]

January 15, 1890, and it is recommended that they be adopted by this body as thus revised, and promulgated to members."

With the report a graphic diagram was handed in, which showed that, while electric wires and lights were responsible for losses of only $460,000 in 1886, the value of property injured by fire which could be traced to the same sources in 1889 was $5,533,000.

The Board agreed to adopt the rules of the New York Board in the regulation of electric light equipments, and appointed W. A. Anderson, Superintendent of Surveys of the New York Board, to meet a committee of experts at the invitation of the National Electric Light Association, to recommend rules which will make electric lighting safer all over the country.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Fire Department Underground Cables.—The Kemmler Proceedings. —Cable Road Litigation.

BIDS were opened on May 7th, at Fire Department Headquarters, for "Placing Fire Alarm Electrical Conductors Underground in New York City." The Standard Underground Cable Co. was the successful bidder at $47,771.59. The specifications include the furnishing and laying of 30,000 feet of two inch pipe and 650,000 feet of No. 14 conductor in "Standard" lead covered underground cables, braided and painted with "P. & B." paint. Work will be commenced immediately.

The Kemmler execution matter continues to excite interest, and will attract even more attention when the question comes before the United States Supreme Court, on the argument for a writ of error on May 19. To secure the granting of his application, counsel must show that a federal question was involved necessarily and essentially in the conviction and sentence of Kemmler. In the meantime, another writ of habeas corpus has been issued in the case of Kemmler, the murderer. The writ was granted by Judge Corlett and was obtained by Charles S. Hatch. It is issued to dispose of the question as to whether the warden of the state prison at Auburn, can legally execute. A stay of execution was some time ago asked upon the same ground, Mr. Hatch urging that nobody but the sheriff of Erie County could execute his client.

The Third Avenue Railroad Co. has again been refused permission to substitute cable for horse power. The General Term of the Supreme Court has sustained Judge Patterson in his opinion that the company's charter does not allow it to use cable power. Presiding Justice Van Brunt, who writes the opinion, says that the additional grant sought by the railroad company is contrary to the provisions of the constitution, which prohibits the imposing of additional burdens upon the streets without the consent of local authorities.

NEW YORK CITY, May 10, 1890.

PHILADELPHIA.

The Local Telephone Service.—Telephone Infringement Suits.

After the fitful fever of agitation, the telephone service of Philadelphia is improving. Chairman B. F. Andrews, of the Grocers' Investigating Committee, has received a large number of assurances from subscribers, orally and by letter, that the telephone company is doing much better in serving its customers. Mr. Andrews, with A. A. Keene, representing the Commercial Exchange; L. H. Lapp, of the Drug Exchange, and R. C. Lippincott, of the Lumberman's Exchange, called on President Merrihew, of the telephone company, recently. The delegation was cordially received, and assured that the company was making every effort to give Philadelphia as good service as any city. It was stated that the new building of the telephone company on Market below Fifth would be occupied about the 1st of October, when the wires would be underground in the business section of the city. As fast as the wires are put underground the metallic system will be adopted. The switch-board for the new building and system has been ordered to be ready on July 1, and will cost $100,000. President Merrihew stated that 154,000 miles of overhead telephone wires are strung in the United States, and 27,000 miles of underground wires. He cited as one reason for trouble with the service in this city the compulsory use of roofs instead of poles for the wires.

Summonses have been served from the United States Circuit Court in eight equity suits, brought by the Bell Telephone Company to have parties enjoined from using telephones alleged to contain infringements on the Bell patents. The defendants are the well known Thackara Manufacturing Company, John W. Stelwagon, John H. Rose, John S. Fanning, William B. Rambo, J. Rex Allen, John E. Morton, M. Lippman & Bro., Alonzo Hillier and James W. Queen & Co.

PHILADELPHIA, May 8, 1890.

BOSTON.

Legislative Notes.—Boston Electric Club.—West End Railway Work.

THE Legislature has been busy this week, considering various electrical questions, and has got through considerable work. The Meigs' bill, which had been favorably reported was finally re-committed and it will come up again for reconsideration, along with all other elevated railroad questions, on May 15th. The West End company have thus scored a point in the battle, as their bill will be reconsidered at the same time. The Meigs bill allows any street railroad to adopt that system, on permission of the city council of the city. The West End people will ask to have this permission made applicable to any system. In that event, the simple vote of the city council will permit them to elevate their tracks through the business part of the city, run their cars on them, and make the elevated a part of their surface system. The House appears to be friendly towards the West End bill, and if the West End bill goes through it will mean the death of the Meigs system, so far as Boston is concerned, for with the West End tracks elevated through the business part of the city, any independent system of elevated roads will not be thought of for years.

A bill has been reported to provide that electric light and power companies may mortgage their rights and franchises to secure payment of their bonds. A vote of a majority in interest is necessary; interest is not to exceed 6 per cent., and no bonds shall be issued to exceed the capital stock actually paid in.

The bill which has passed the State Senate and is now before the House, authorizing the consolidation of gas and electric companies is exciting a great deal of interest. It permits any gas or electric light companies in this state to combine by the vote of the stockholders, without any adequate guarantees against wholesale stock watering. The consolidated company is to appoint one appraiser, the commissioner of corporations another, and these two a third, who shall appraise the properties, and upon their appraisal fix the amount of stock that may be issued. In the House a communication was received from the attorney-general on the order of inquiry as to whether cities and towns have authority to construct and maintain within their own limits and for their own use, systems of lighting by gas or electricity; and whether they may sell gas or electricity for private use. The opinion of the attorney-general is that cities and towns have not such authority.

The Senate has passed to be engrossed the bill authorizing the Boston Electric Light Co. to increase its stock by $2,000,000.

At a regular monthly meeting of the Boston Electric Club, the proposed amendment of the constitution and by-laws was acted upon, and several important improvements accepted. Thirteen new members were admitted and very encouraging reports were made. The next monthly dinner of the Club will be held on Wednesday, May 21st (not May 19th, as on the bulletin) at the Parker House, when Mr. S. E. Barton, of the Electric Mutual Insurance Co., will read a paper on "The Relations between Fire Insurance and Electric Interests from the Underwriter's Standpoint." The change of date was made, so as to entertain the members of the American Institute of Electrical Engineers, who have their annual meeting in Boston, on the 21st and 22d of May. A formal invitation has been extended to the Institute, for as many members as may attend the meeting.

The West End Street Railway Co. are making arrangements to operate the Blue Hill Avenue line by electricity. In order to obtain more power quickly for the operations of their rapidly extending system the West End company will make arrangements with the Edison Illuminating Co., to rent about 1,000 h. p. from them for the summer time, which naturally is the slack period of any lighting company. Thomson-Houston generators will be installed and the Illuminating company will supply the power.

BOSTON, May 10, 1890.

CHICAGO.

A Plant for Cold Rolled Steel Wire.—Details of the Detroit Motor.

A COMPANY with a capital stock of $500,000 has been formed in this city for the manufacture of cold-rolled steel wire, and will at once construct an extensive plant. The patent for the only machine in the world for the cold-rolling of steel wire is said to be owned by this company and the prospects are considered good that an important industry will thus be built up at this point. The rolling of cold steel wire is accomplished with great ease under this process, and repeated tests have shown that the wire so produced is not only not weakened by the process, but, rather, that its tensile strength is nearly doubled. Thus, the tensile strength of hot-drawn wire is 56,460 pounds to the square inch, while that of the cold rolled steel wire runs up as high as 105,800 pounds. The machines to be used are the outgrowth of those invented a few years ago for rolling taper shapes, in which the wire to be reduced or tapered was subjected to the action of rolls grooved to conform to the taper desired. In working these machines it was discovered that steel wire reduced by this process was both softened and strengthened. Thus, the wire rolled by the new machine proves to be very malleable, it being possible to knot it, twist it and hammer it in a way the metal would not stand in its original condition, while a round, square, octagonal or hexagonal wire can be produced as desired. Another product of the machine is a cold-rolled copper wire with a steel core, produced by passing a steel bar through a copper pipe, which is then passed through the rolls. The ratio of diameters of the two metals is always maintained, showing that the rolling affects the metal uniformly throughout. A local corporation is negotiating for the exclusive right to manufacture this steel-cored copper wire for conducting electric currents, for which it is especially adapted, the copper furnishing the necessary conducting medium, while the steel core gives a much greater strength than it has been possible to obtain in copper wire. Experiments with steel, iron, copper, brass and german silver have given equally satisfactory results. The site for the new plant will probably be convenient to the river, and with a force of about 50 men it is expected that from 75 to 100 tons of wire a day will be made at the outset.

Mr. Armour, the representative of the Detroit Motor Co. in this city, is meeting with considerable success with these motors. They are very compactly built, and show solid mechanical construction throughout, and have a very handsome and tasteful appearance. The motors run without any sparking at the commutator whatsoever, thereby reducing expenses attendant on the wearing parts, of which the commutator is the most expensive, to a minimum. An ingenious switch is employed with these motors which may be said to combine in one piece of mechanism the switch, rheostat and magnetic cut-out. On the first movement of the switch handle the current is on, and by further movement the resistance coils are gradually cut out and finally the switch is maintained in position by a magnet energized by the current; if any cessation should occur in the current the magnet releases the switch which thereupon automatically retraces its way step by step over the resistance coil to the dead point. This action is obtained by a spring. This switch is a very useful adjunct to the motor as it practically takes care of the motor and prevents a burn-out and the machine when running requires no attention whatsoever, an important point when it is considered that motors are usually placed in the hands of anyone but experts and oftentimes receive the worst possible treatment.

CHICAGO, May 9, 1890.

ST. LOUIS.

City Lighting.—The St. Louis Exposition.—Electric Railway Work. Lighting at Lebanon, Mo.

The long expected electric lighting of the city is now an accomplished fact. Promptly at 7.30 P. M., May 1st, the 1,850 arc lights of the Municipal Electric Lighting and Power Co. were turned on. A few interruptions occurred during the first few nights, but everything is going on smoothly now.

E. V. Matlock, supervisor of city lighting, has submitted his first annual report and an estimate of the funds required by his department for the current year, of which the following is a summary :—

For lighting with gas or electricity public buildings not now lighted by electricity	3,275 00
ELECTRIC LIGHT.	
For lighting streets, alleys and parks	176,000 00
For salaries of supervisor, clerk and inspectors	8,500 00
For furniture, printing and stationery, apparatus, incidental expenses	3,300 00
For electric lighting of public buildings	38,000 00

The management of the St. Louis Exposition have engaged Mr. Fred. H. Whipple, of Detroit, to manage the electrical exhibit next fall. The exhibit will be made much larger and more varied in every way than last fall's display. Some of the novelties already booked are: Filtration of water by electrolysis, by the Stanly Electric Co., of Philadelphia. The Carpenter-Nevins Electric Heating Co., of Minneapolis, Minn., the Talmage Heating Co., of Kansas City, and the Burton Electric Heater Co., of Richmond, Va., will exhibit their improved heaters. The new Westinghouse Electric Railway Co. will have a complete power station and road in operation. The Electrical Accumulator Co., of New York, and the Edison Phonographic Doll Co., of New York, will make exhibits. Gold, silver and bronze medals will be awarded to all classes of electrical appliances. Mr. Carl Hering has been appointed by the American Institute of Electrical Engineers, and Mr. E. R. Weeks has been appointed by the National Electric Light Association to act as an awarding committee. A third member will be selected by the entire electrical fraternity, but his name will probably not be announced until July.

The Baden and St. Louis Railroad Co., a suburban road connecting with the northern end of the St. Louis railroad, have introduced a bill before the municipal assembly asking for the privilege of changing their motive power to electricity, either by overhead wire or storage battery.

The Forest Park, Laclede and Fourth Street Railroad and the Missouri Railroad (Market street section), have accepted the ordinances passed at the last session of the assembly, have filed bonds and will begin work immediately.

The East St. Louis City Council have granted an exclusive franchise to the East St. Louis Electric Railway Co., of which Henry D. Sexton is manager. The franchise authorizes the company to construct and operate four lines covering the important parts of East St. Louis. The capital stock of the company is $150,000 with the following incorporators, all of East St. Louis: Daniel Sullivan, Paul W. Abt, Edmund Wallace, C. T. Jones, H. F. Bader, Fred. Libar and Henry D. Sexton. In consideration of this franchise the company are to pay the city $5,000 in cash. The roads are to be completed in six months. Fare for all parts of the city five cents. The granting of this important franchise was something of a surprise. It was generally supposed that the St. Louis and East St. Louis R. R. would get the franchise.

The Lebanon, Mo. City Council have passed an ordinance granting an electric light franchise to B. F. Hobart, of St. Louis, for a period of 20 years. Both arc and incandescent lights will be used. The city agree to take 23 arc lights at $3,000 per annum, with the privilege of additional lights at $120 per annum. The franchise stipulates that Mr. Hobart and his associates are to erect a $100,000 hotel and bath house at the magnetic well. The ordinance is subject to a ratification by the citizens and an election for that purpose will soon take place.

ST. LOUIS, May 9, 1890.

PITTSBURGH.

Westinghouse Electric Company's Directorate—Western Union Standard Clock System Company—Electric Railway Work.

At a meeting of the Westinghouse Electric Company, which was held last Monday morning, the following board of directors was elected: Geo. Westinghouse, Jr., president; Henry M. Byllesby, R. Pitcairn, John Caldwell, J. R. McGinley, Calvin Wells and Chas. S. Pease. At the same time the Westinghouse Electric and Manufacturing Company held a meeting for a similar purpose with the following result: Geo. Westinghouse, Jr., president; Henry M. Byllesby, Robert Pitcairn, C. H. Jackson, G. W. Hebard, J. R. McGinley, Calvin Wells, H. R. Garden and A. M. Byers. Since that meeting was held the directors have called a special meeting of the stockholders to take place July 8, for the purpose of voting for, or against, an increase of the capital stock of the company. On that day the formal transfer of the business of the Westinghouse Electric Company to the Electric Manufacturing Company will also be made. The increase of the capital stock of the company is to be made on account of the fact of the company having entered into the manufacture of electric street railway appliances.

The Western Union Standard Clock System Company has been organized in this city for the purpose of supplying business houses and private residences with the correct time. Mr. J. G. Munson, who is in charge of the Western Union Telegraph office at the East End Stockyards is the manager of the company. He has just completed arrangements to give the correct time by wire from Washington, D. C. The time is to be transmitted every hour, all the clocks being electrically connected with the wire which runs from the Observatory in Washington. A number of clocks have already been subscribed for, and the company expects to have about 50 of them in operation by the first of June.

A limited corporation with a capital stock of $10,000, known as the National Electric Company of Wilkinsburg, has applied for a charter. Wilkinsburg is a small suburb of Pittsburgh. The new concern purposes to manufacture electrical appliances.

Over two hundred men are now daily employed on the line of the Duquesne Traction Company, engaged in putting down the tracks; and the management of the road have promised the Pittsburgh people that they will have their cars running by the first of October.

The North Allegheny Electric Railway Company has been organized, and the incorporators are pushing the work on the line as rapidly as possible. When finished this will make another feeder for the Pleasant Valley Electric Line, taking passengers from Pittsburgh across Allegheny City for several miles out the Perrysville Road. It will give strangers coming into Pittsburgh an opportunity to travel from the post-office direct into the very center of a busy petroleum producing centre. And all this can be done on the axles of the electric car.

An electric street railway is about to be built in Greensburg, forty miles from this city. The contract for a large part of the work was let the other day.

PITTSBURGH, May 9, 1890.

"TELEPHONE ENGINEERING."

Mr. J. J. Carty, the well-known electrician of the Metropolitan Telephone Co., of this city will deliver an address before the New York Electrical Society at Columbia College on Thursday, May 15, at 8.15 p. m., on the above interesting subject. It will be a practical talk on the various departments and details of telephonic work.

LETTERS TO THE EDITOR.

THE IRON-DIOXIDE OF MANGANESE STORAGE BATTERY.

[126]—Noticing in your issue of April 2, a secondary battery invented by one, Hollingshead, of Bronxville, N.Y., in which he claims the use of dioxide of manganese and metallic iron with an electrolyte having in solution an acid salt, I was led to experiment with the same, using for an electrolyte a five per cent. solution of bichromate of potassium and water. I used a porous pot in which I placed an iron plate and then filled the pot with dioxide of manganese, placing the whole in a glass jar for containing the electrolyte as above, and putting around the same a piece of sheet iron cut from a stove pipe.

I then charged the same with four acid batteries for half an hour, then discharged them through a bell having about two ohms resistance; the bell vibrated exactly three hours, I then charged the cells 10 minutes and discharged them through the bell for 57 minutes. I think this may be considered an excellent showing for the storage battery.

The surface of the negative plate of the cell was 70 sq. in. and the dioxide of maganese, which was the positive, consisted of 3½″oz. of crystals placed around the iron in the porous pot ¾″ x 2⅝″ x 4½.″ The pot was placed in a glass jar which holds about a pint of solution.

The electromotive force of the cell is lower than that of the lead battery but it has many advantages over the latter, some of which I wish to point out. Comparing the properties and action of the lead cells with the one under consideration we have:

Lead, Pb; atomic weight, 207; lead oxide, $Pb\,O_2$. The total quantity of oxygen in 5 pounds of the latter is 4,686.1 grains, and the *available* oxygen 2,443 grains. The weight of lead per cubic foot is 709.5 pounds. The number of molecules of water, $H_2\,O$, transposed in one reaction is 1.

Iron, Fe; atomic weight, 56; oxide of iron, $Fe_2\,O_3$. The quantity of oxygen in 5 pounds of the latter is 10,500 grains, and the *avaible* oxygen 3,500 grains. The weight per cubic foot of iron is 450.5 pounds. The number of molecules of water transposed in one reaction is 2.

The above comparison I have only made to prove that, to my mind, the iron battery is far ahead of any known lead storage battery.

The advantages it possesses over the other are lighter weight, and the absence of blistering, sulphating, buckling, together with the avoidance of acids and the continuous charging when first set up. Besides there is no danger of short-circuiting between the plates. It is cheaper in construction and more economical to use and requires no skilled attendance to take care of it.

There is no appreciable local action as, after using the same, charging and discharging it day and night for weeks, I weighed the plates and found them to be unaltered.

The only thing that might have changed was the solution. Some may be skeptical about the claims I make for this battery, but there is only one way to settle this point and that is to let them experiment with it. I believe this is the long-sought-for storage battery.

H. BLUMENBERG.

MT. VERNON, N. Y.

HAS KEMMLER BEEN ELECTROCUTED?

If the following circumstantial report of Kemmler's execution be true it is evident that the New York daily papers have been sadly left. We take it, *verb. et lit.*, from *The Weekly Sentinel*, of Port Arthur, Lake Superior, Ont., of Friday, May 2, 1890:

ELECTROCUTION.

PAINLESS DEATH OF MURDERER KEMMLER.

He Dies in Auburn Jail Without a Struggle—The Process Worked Well, as Death was Instantaneous—Scaffolds Will Soon Be No More.

[Special to the SENTINEL.]

AUBURN, N. Y., April 30.—The much talked of electrocution of Kemmler took place this morning in the presence of twelve reputable citizens, the jail surgeon and his assistant, the State electrician, the warden, turnkeys and others, and also of Rev. Dr. Houghton, pastor of the First Methodist Episcopal church. The condemned man was resigned to his fate and acknowledged its justness, saying that he sincerely repented for his crime.

There was no hitch whatever about the electrocution. The methodical regularity of carefully trained men served to make everything go smoothly. A procession from the doomed man's cell filed out early this morning led by Rev. Dr. Houghton. When the dismal procession arrived at the cell where the electric apparatus was constructed, Kemmler was quickly placed upon the death chair and pinioned so that he might receive the full shock. Then his spiritual adviser repeated slowly the words of the Lord's prayer, the doomed man repeating it after him. When he came to the words "For thine is the kingdom, the power and the glory," the electrician in charge of the apparatus touched the electric button sending the charge of over 7,000 volts through the chair and its unfortunate victim.

The sternness of Kemmler's features suddenly relaxed. There was just a visible shudder and that was all. None of the unmerciful contortions and stranglings and convulsions which mark the death of a man by hanging. Death was instantaneous. Everyone present was greatly relieved at the sudden termination of what they had forebodings would be a ghastly sight, and when in 11 minutes the jail surgeon pronounced life absolutely extinct, a sigh of satisfaction was distinctly audible.

This is the first death by the new process of electrocution. It is now to be sincerely hoped, as the system has been proven to be safe, quick and reliable, that there will be no more hangings. The days of the scaffold are almost at an end. The feeling is that if we must have an extreme penalty then that extreme penalty should be exacted only in the most modern and painless way. When a man must pay for a crime with his life, his life should be taken from him with as little brutality a possible.

LITERATURE.

Electric Light Installations and the Management of Accumulators. By Sir David Salomons, Bart., M. A. New Edition, revised and enlarged. New York: D. Van Nostrand Co., 1890. 334 pp. Price, $1.50.

IT is not often that the user of electrical apparatus has the time to devote to its intelligent and systematic study and this is all the more to be regretted as such observers are usually devoid of prejudice or bias and pursue the subject mainly for their own satisfaction and the benefit which may accrue to the others from their own experience. Sir David Salomons has long been known as an electrical amateur of far more than ordinary ability and his excellent little volume on the "Management of Accumulators," has deservedly had a large sale and has, perhaps more than any other book, served to give the student and the public at large a clear idea of the capabilities of storage batteries.

In the latest edition of Sir David's work are embodied the results of his most recent experiences, which go far to show that with the exercise of ordinary judgment and care, these batteries may be depended on for reliable service. It is fortunate that the author has had the advantage of ample means and facilities for carrying out his ideas and has gone about his work systematically, with the result that he is able not only to lay before the reader the best rules to follow for the management of accumulators from the time of their reception from the makers until they are in regular continuous service, but to discuss the important item of the cost and expense of operating a storage battery plant.

Recognizing also the desire of many non-professional persons and intending purchasers to be informed on the various apparatus in the market, the author has added several chapters to his original work descriptive of a large variety of details which go to make up a complete electric lighting plant. Although, naturally, the products of English manufacturers alone are described, the particular functions of each are so fully dwelt on that their description may be read with much profit by the American reader as well.

The work being intended more as a record of experience than a scientific treatise on the subject, a rigid criticism of it is superfluous. The errors that it embodies are not serious enough to require special mention.

It is written in a pleasing conversational style, is well calculated to interest and instruct those operating storage battery plants in particular, and is worth a baker's dozen of the average semi-theoretical books made up chiefly of principles that have never been tried and of practice that has well nigh been forgotten.

A SOLID ACCUMULATOR.

In a recent issue the London *Electrical Engineer* describes a dry storage battery in which the whole cell is much of the same consistency as a bathbrick, and can, therefore, suffer nothing by shaking. The modification mentioned is the invention and patent of Mr. Barbey-Starkey, whose name is so well known by his method of adding carbonate of soda to batteries to prevent sulphating. In the new solid accumulator the interstices between the battery plates are filled with a mixture of fine white wood sawdust soaked in the sulphuric acid solution and mixed with plaster of Paris. This mixture sets fairly hard and the whole cell is practically a solid mass. The cells have been tested experimentally by the Electric Traction Company at Barking, and it seems that, so far as the tests have yet extended, that the combination is very satisfactory. The internal resistance of the battery is not increased and the efficiency is the same, while the battery is only a shade heavier. A few cells have only as yet been tried, and the batteries have not yet been put to a practical working test.

REPORTS OF COMPANIES.

NEW ENGLAND TELEPHONE AND TELEGRAPH COMPANY.

The annual report of the New England Telephone and Telegraph Company for 1889 shows :—

	1889.	1888.	Increase.
Earnings	$1,255,570	$1,127,807	$123,263
Expenses	957,305	856,580	100,724
Net	$298,265	$270,726	$27,538

The company made liberal expenditures for betterments, charging more or less to expense account. Of the charges to new construction, $318,169.17, $190,000 has been expended for underground work, and $88,000 for extension of the extra territorial and toll lines. There were 124,405 feet of new cable placed in use in the Boston Exchange. The amount of underground wire in use at the end of the year was 3,599 miles, about two-thirds of the entire amount used in operating the exchange. No other city, except New York, has so much telephone wire underground. The company has now in use, in its various exchanges 446,470 feet of cable—aerial, submarine and underground—carrying 6,600 miles of copper wire. The company expended during the year for construction, $331,191 ; for re-construction, $106,956, and for repairs, $216,289, a total of $654,438, against $469,157 in 1888. The mileage of exchange wires December 31 was 19,784.

	Dec. 31, 1888.	Dec. 31, 1889.	Increase.
Exchange subscribers	15,536	16,719	1,183
Express subscribers	549	556	7
Private lines and agency stat's	2,847	3,178	331
Total	18,932	20,453	1,521

The increase of the number of stations during 1888 was 1,576. To effect the increase of 1,190 in the number of exchange and express subscribers, as shown by the foregoing statement, new subscribers have been connected, 4,731 ; subscribers disconnected, 3,541 ; difference, 1,190. The extra territorial lines number 76 ; miles of extra territorial pole lines, 2,180 ; miles of extra territorial wire, 5,048. Patent 413,276 was issued to the company on October 22, 1889, for "Central station calling apparatus," invented by Mr. Farnham. Applications have also been made for patents on a new form of underground cable covering and a double trolley crossing switch. The report deals with the interference with the telephone service of the electrice car lines and the efforts to diminish this interference. "Notice has been served as to operating, or indicating the intention to operate, the single trolley system upon their roads, in proximity to our wires, that the use of the electric current applied in that way is injurious to our business and an invasion of our rights, and that we shall hold them responsible for any damage to our interests resulting from that cause. It is the purpose of the management to employ such means as may be necessary to obtain relief from disturbance of this nature, and redress for the injury which we may suffer." The affairs of the company are declared never more prosperous. The estimated expenditures for 1890 are $350,000 for construction, $100,000 for reconstruction, and $650,000 for repairs. The net earnings were as above, say :

Net earnings	$298,265
Undivided earnings, Dec. 31, 1888	113,226
Total	$411,491
Dividends 1889	270,726
Balance	$140,765
Surplus account Jan. 1, 1889	373,525
Adjustment	11,250
Surplus account Dec. 31, 1889	$362,275

The balance sheet Dec. 31, 1889, was :

DEBTORS.

Licenses	$4,268,000.00
Plant	6,349,860.12
Unissued stock	1,605,400.00
Trustee stock	231,000.00
Stock and bonds	29,116.90
Construction (for the year 1889)	318,169.17
Office furniture, teams and tools	22,951.49
Bells, material and supplies	218,354.80
Accounts receivable	169,879.01
Cash	18,989.70
Total	$13,231,721.19

CREDITORS.

Capital stock	$12,000,000.00
Surplus account	362,275.72
Income account	140,765.27
Reserve account	153,213.23
Unpaid dividends	1,150.25
Bills and accounts payable	74,316.72
Loan of 1889	500,000.00
Total	$13,231,721.19

At the annual meeting of the company in New York these officers were chosen :— President, Thomas Sherwin ; vice-president, Henry S. Hyde ; treasurer, William R. Driver ; secretary, Fred. J. Boynton ; general manager, J. N. Keller ; board of directors, Fred. Ayer, Benjamin C. Dean, W. H. Forbes, John E. Hudson, Henry S. Hyde, A. O. Morgan, Moses G. Parker, Stephen Salisbury and Thomas Sherwin.

UNION TELEGRAPH AND TELEPHONE CO.

The treasurer of the Union Telegraph and Telephone Co. has presented the following quarterly statement to the directors at Lowell, Mass. :—

Gross earnings	$6,036.80
Gross expenses	4,960.23
Surplus	$1,076.57
Dividend No. 6	1,000.00
Surplus	$76.57
Surplus to Jan. 1	$1,072.80
Total to date	1,749.37

ERIE TELEGRAPH AND TELEPHONE CO.

The Erie Telegraph and Telephone Co. directors have declared a quarterly dividend of one per cent., to be paid by check mailed to stockholders, May 19, 1890, that are of record at noon, Friday, May 9. The stock books, on account of the dividend and the annual meeting, closed at noon, May 9, and will open Wednesday, June 11, 1890. The Cleveland Telephone Co., the Northwestern Telephone Exchange Co. and the Southwestern Telegraph and Telephone Co. report for the three months ending March 31, 1890, as follows :—

Gross income		$182,462.72
Gross expenses (including dividends payable May 19)		179,861.23
Surplus		$2,601.49
SUBSCRIBERS.		
Number connected Dec. 31, 1889	11,995	
Added during the quarter	250	
Total number connected March 21, 1890	12,245	
Proportion of dividends received by the Erie Telegraph and Telephone Co		$49,840.90
Dividend No. 26		48,000.00
Surplus		$1,840.00

OUTPUT OF BELL TELEPHONES.

The Bell Telephone output for the month ending April 20 was as follows :—

	1890.	1889.
Gross output	6,062	5,314
Returned	1,892	1,913
Net	4,170	3,371
Since Dec. 21.	1889–90.	1888–89.
Gross	18,881	17,803
Returned	8,042	7,619
Net	10,839	10,214

THE TELEPHONE IN MEXICO.

At the annual meeting of the Mexican Telephone Company, in New York on April 16, the old officers and board of directors were unanimously re-elected. Nearly 100,000 out of 168,000 shares outstanding were represented. The figures of operations for the year ended March 31 make the following comparisons :

Year March 31.	1889–90.	1888–89.	Increase.
Gross receipts	$68,190	$57,954	$10,236
Expense and construction	39,370	43,428	*4,058
Net	$28,820	$14,526	$14,294

*Decrease.

The instrument output was increased by 138 telephones, of which 100 were in the City of Mexico. The construction account showed a large increase, which in the City of Mexico increased $6,000. The five sub-stations showed increases in the construction account varying from $550 to $2,000. During the year $8,000 of old indebtedness left by former managements was paid.

Beginning with April 1, the publishers of **The Electrical Engineer**, New York, will issue that paper weekly instead of monthly as heretofore. The high position which the paper has always held in electrical journalism will undoubtedly be maintained, and the change will be a welcome one to the readers. We wish our contemporary the most abundant success in its progressive venture.—*Stationary Engineer.*

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

Mr. R. W. Pope, the secretary of the Institute, has issued an important and interesting circular with regard to the annual meeting on May 20 and 21. The Institute has not held a meeting outside New York since 1884, when it held one in Philadelphia, at the time of the Electrical Exhibition, and there is every indication of a large and successful meeting in Boston, as the Institute has a large New England membership.

The annual meeting of the Institute for the election of officers for the ensuing year and the transaction of other business, will be held at the House of the American Society of Civil Engineers, 127 East 23d street, New York city, Tuesday evening, May 20. The rules require the election to be held in New York, but it is proposed to amend this so that it can be held wherever the annual meeting for the reading of papers takes place.

The terms of the following officers expire on that date in accordance with the Rules: *President*, Prof. Elihu Thomson; *Vice-Presidents*, Dr. Louis Duncan, Francis R. Upton, T. Commerford Martin; *Managers*, Dr. Schuyler S. Wheeler, Joseph Wetzler, Francis B. Crocker (Vice A. C. Fowler), John W. Howell (Vice Wm. Lee Church); *Treasurer*, George M. Phelps; *Secretary*, Ralph W. Pope.

The terms of the following members of Council do not expire this year:

Vice-Presidents, Edward Weston, Major O. E. Michaelis, (deceased,) Dr. Edward L. Nichols. *Managers*, Charles Cuttriss, George B. Prescott, Jr., Thomas D. Lockwood, William Maver, Jr., Dr. F. Benedict Herzog, Dr. Wm. E. Geyer, H. C. Townsend, Henry Van Hovenbergh (resigned). The vacancies caused by the death of Major Otto E. Michaelis, Vice-President, and the resignation of Henry Van Hovenberg, Manager, will be filled by Council.

After the conclusion of the regular business of the annual meeting, the following paper will be read:—"Electricity in the Navy," by Mr. Gilbert Wilkes, late of the United States Navy.

Upon the adjournment of the meeting the evening of May 20, those who intend taking part in the General Meeting at Boston, May 21, will re-assemble at the Grand Central Depot, 42d street, in time for the Shore line train for Boston at midnight.

WEDNESDAY MORNING.

The General Meeting for the reading and discussion of professional papers will be held at the "new building," Massachusetts Institute of Technology, corner of Boylston and Clarendon streets, Boston.

The morning session on Wednesday will be called to order at 10 o'clock.

The proceedings will be opened with an address of welcome by Gen. Francis A. Walker, Ph. D., L.L.D., President of the Massachusetts Institute of Technology.

After a response by the President, the following papers will be read:

"Electric Lighting in the Tropics," by Wilfred H. Fleming, of New York city.

"Magnetic Data of the Sprague Street Car Motor," by H. F. Parshall, of New York city.

"Note on a New Photometer," by Dr. Edward L. Nichols, of Ithaca, N. Y.

"The Limitations of Steam and Electric Transportation," by Oscar T. Crosby, of New York city.

A 1 P. M. a recess of one and a half hours will be taken.

AFTERNOON SESSION.

2.30 o'clock, Wednesday, May 21.

"The Industrial Utilization of the Counter Electromotive Force of Self-Induction," by Thomas D. Lockwood, of Boston.

"A Study of Arc Light Carbons," by Louis B. Marks, of Cornell University.

"The Practical Aspects of Alternating Current Theory," by Dr. Michael I. Pupin, of New York.

"Automatic Electric Welding Machines" (with Experimental Demonstrations), by Hermann Lemp, Jr., of Lynn, Mass.

Miscellaneous business.

WEDNESDAY EVENING.

The members of the Institute will be the guests of the Boston Electric Club at a dinner, the hour and place of which will be announced on Wednesday. A paper will be read under the auspices of the Club, by Stephen E. Barton, of Boston, on "Central Station Insurance."

The headquarters of the Club are at 7 Park street, where members will be welcome during their visit to the city.

The headquarters of the Secretary will be in Parlor E, on the office floor at the Brunswick, directly opposite the Massachusetts Institute of Technology. Other hotels in the immediate vicinity are the Vendome and the Thorndike. The Tremont, Parker House and Young's Hotel are within a convenient distance.

Transportation.—A special car will be provided on the midnight train from New York to Boston, May 20. The fare, including berth, is $6 one way. Those who desire accommodations in this car will please make early application to the Secretary, in order that all may be properly provided for. No remittance is necessary at present.

Members are requested to make their own arrangements direct for rooms at the Brunswick or such other house as they may prefer. The rates at the Brunswick are $5 per day, or $6 with bath.

A cordial invitation is extended to all persons interested in electrical progress to attend the sessions of the General Meeting, and New England members are especially requested to call the attention of their friends to this fact.

The thoroughly equipped Electrical and Engineering laboratories of the Institute of Technology will be thrown open for the inspection of all. It is also understood that one or two special excursions will be organized.

GLASS INSULATED WIRE.

According to recent reports, an inventor by the name of Thomas S. Reed has devised a conductor in which insulation is depended upon principally by a layer of spun glass. The method employed consists in first winding the wire with slack-twisted yarn, either cotton or woolen, and overlaying it with longitudinal strands of spun glass. Outside of these a strand of spun glass, intermixed with silk, is wound in a close spiral, and over that a braided covering of cotton, wool, hemp, flax, silk or fine wire. The whole is coated thickly with paraffin or thick varnish, if the wire is to be exposed to dampness. For that which is laid or buried under cover, soluble glass is used.

If the wire is to stand hard usage, all the glass strands are loosely twisted with silk, flax or other suitable fibre, before being applied. The wire can be glass-wound a number of times if necessary, but twice is generally sufficient. The first winding, which acts as a cushion, holds the glass strands in place, and the spiral row compresses them into an impervious surface. For extra security another spiral is wound the reverse way. The braided outer cover not only guards against the insulation's never slipping or cracking, but supplies a method of covering wires that is claimed to be practically indestructible.

THE MEASUREMENT OF ELECTRO-MAGNETIC RADIATION.

At the last meeting of the Physical Society of Berlin, Dr. Rubens spoke on the employment of the bolometer for observing the electrical radiations of Hertz as carried out by himself and Dr. Ritter. Up to the present it had not been found possible to measure the intensity of the radiation, owing to the extraordinarily minute amplitude of the oscillations; but the speaker had been able to carry out the determination by means of a special form of bolometer. It consists essentially of an accurately balanced primary Wheatstone bridge, two of whose arms are again converted into secondary Wheatstone bridges. If a current passes through one of them its resistance is altered by the rise of temperature, and the galvanometer gives a proportionate throw. A similar effect is produced by a wave of electrical radiation, and hence its amplitude can be measured by this bolometer when once it has been calibrated. When experimenting with the polarizing wire-grating it was found that there is a constant relationship between the intensity of the rays which pass the grating and the angle of inclination of the wires to the plane of oscillation of the rays. It was further observed that the energy which does not pass the grating is reflected, and to the extent of 98 per cent., when the wires are at right angles to the plane of oscillation.

THE TATLOW BATTERY.

This battery is composed of a zinc and peroxide of lead couple in dilute sulphuric acid. The peroxide of lead is obtained as follows: A lead foundation plate is filled in with a paste of lead oxides, made of red lead and sulphuric acid, or litharge and lead acetate solution—a plate, in fact, similar to an ordinary storage battery plate. When the paste has set hard the plate is placed in a solution of chloride of lime, whereby the salts and oxides of lead are gradually oxidized to lead peroxide, the rapidity of the reaction depending on the temperature and degree of concentration of the solution. It is absolutely necessary that there should be enough free lime present to keep the liquid alkaline. When completely oxidized the plate is taken out of the solution, well washed, and is ready for use in the cell, giving with zinc and dilute sulphuric acid an E. M. F. of 2 to 2.3 volts. After the plate has ceased to be active it is to be washed and returned to the hypochlorite solution. The same plate thus serves again and again, acting as a carrier of oxygen between the hypochlorite and the zinc. The reaction in the hypochlorite solution possibly involves the formation of a lead or lead-calcium hypochlorite during the process.

LEGAL NOTES.

HAND-OPERATED ELECTRIC GAS LIGHTING APPARATUS.

CIRCUIT COURT OF THE UNITED STATES, DISTRICT OF MASSACHUSETTS.

Electric Gas Lighting Co., *et al.*
vs. } *In Equity.*
Charles E. Fuller, *et al.*

COLT, *J.:*

This is a bill in equity brought for the infringement of letters patents No. 225,071, granted to Henry F. Packard, and No. 232,304, granted to Frank V. Sanford, for improvements in electric gas-lighting apparatus. The patents relate to that form of electric gas-lighting where the burner is operated by hand, and which does away with the use of matches.

Packard says in his specification:—

"My invention consists in certain novel devices, hereinafter fully described, by means of which the gas is turned on by pressing or pulling down and then releasing a lever fitted loosely to the stem of the cock, and thereby causing a vibrating arm to sweep past the tip of the burner; also, in the combination, with the said devices, of an electric contact-point fixed upon the end of the said vibrating arm, and of a fixed electrode located in close proximity to the orifice from which the gas issues, one of the said electrodes being insulated from the burner, and which, by the action of the said devices, are caused to make and break contact when the gas is turned on, thereby producing an electric spark and igniting the gas."

The claims relied upon are the third and fourth, which are as follows:—

"3. In combination with a gas-burner, A, and a fixed electrode, *n*, the ratchet, D, pawl *h*, spring F, lever E, pivoted loosely upon the stem of the cock and having two arms, *f* and *g*, to the latter of which is attached an elastic contact-point, and stop-pin, *k*, as and for the purposes set forth.

"4. In an electric gas-lighting apparatus, in combination with devices constructed and arranged to open and close the gas-passage to the tip at each alternate movement thereof, and conjointly with such opening to ignite the gas by an electric spark generated by such movement, devices which shall, without actuating the gas-cock, repeat the electrical spark by the return movement of the opening devices to their normal position for further use, substantially as described and shown."

The Sanford device is substantially like the Packard, with the addition of a chain which is attached to the arm of the lever. By pulling the chain with the hand, the burner is operated. The apparatus covering both of the patents is called the Packard-Sanford burner, and it appears to have been the first burner of this class which obtained any large degree of commercial success.

The defence mainly relied upon is that there was no invention in what Packard did, in view of the state of the art at the time. It is not denied by the complainants that every element covered by the claims of the Packard patent may have been old, but it is said that they were never so combined before, and that the result is a great improvement over all prior devices of this class. The complainants insist that it is by taking one element from one prior patent and another element from another that the defendants seek to destroy this patent, and, in answer to this position, they cite the reasoning of the Supreme Court in Parks *vs.* Booth, 102 U. S. 96, where, in stating the rule as to anticipation of a patented combination, the court says:—

"Where the thing patented is an entirety, consisting of a separate device or of a single combination of old elements incapable of division or separate use, the respondent cannot make good the defence in question by proving that a part of the entire invention is found in one prior patent, printed publication or machine, and another part in another, and so on indefinitely, and from the whole or any given number expect the court to determine the issue of novelty adversely to the complainant."

The constituents of the Packard gas-burner are a fixed electrode, a stop-cock with one way or several ways, a ratchet rigidly secured so as to move with the stem of the cock, and having four teeth for a one-way stop-cock, and a proportionably increased number of teeth according to the number of ways through the cock, an angle-lever fitted loosely upon the stem of the cock, one of its arms for operating by hand, and the other extended so as to carry an electric contact-point against and past the electrode fixed at the burner tip when the first arm is depressed, a pawl attached to the lever to engage with the ratchet, a spring to retract the lever when released after being depressed, and a stop-pin to limit the movement of the lever. To light the gas it is necessary to pull down the lever-arm once, whereby the pawl engages with and turns the ratchet which opens the valve and admits the gas through the orifice, while the other lever-arm sweeps past the contact-point across the fixed electrode, making and breaking the circuit and thereby producing an igniting spark; upon releasing the arm, the spring will return the lever to its position, making another spark on its return, and, the pawl not engaging with the ratchet on its return, the gas will be left burning. To extinguish the gas a single pull will revolve the plug so as to close the cock, and the spring will return the lever to its position.

No one of the prior devices, referred to by the defendants, discloses the combination of elements embraced in the Packard patent. Those devices at most contain but a part of the Packard mechanism, and, if practically operative, they seem to have been of doubtful utility. To have constructed the Packard apparatus and so made a practical and useful burner, I think showed invention.

The Smith patent, No. 20,305, shows a ratchet-wheel fixed to a gas-cock, a lever moving freely on the gas-cock, a pawl which engages the ratchet, and an arm carried by the lever to the tip of the burner, but it does not show that the teeth of the ratchet are proportioned to the ways through the cock; nor is the curved magnet of Smith pivoted at its centre and carrying a rod, the two-armed lever of Packard. The Smith arm is not carried past but only up to the burner tip, and from all that appears must be moved forward several times to turn on or off the gas. There are also other differences between the two devices.

The Tirrell patent, No. 232,661, bears a closer general appearance to the Packard apparatus. The date of the Tirrell patent is subsequent to the Packard, but it appears that the Tirrell invention was prior in point of time. But in the Tirrell patent there is missing the ratchet, the pawl, the spring and the stop of Packard. It is said that all Packard did was to apply the ratchet and pawl, which were old, to the Tirrell structure, and that this was not invention. But he did something more than this. We must take the combinations in their entirety, and so viewed I do not think the Tirrell invention destroys the Packard patent. It is clear that the Packard device is a great improvement over Tirrell's, and that the combination of elements employed is different. For the same reason and without entering into the specific distinctions between the two structures, the Heyl patent, No. 58,943, does not anticipate Packard. I find in none of the prior devices the combinations referred to in the 3d and 4th claims of the Packard patent, and, recognizing the prior state of the art, I think it called for the exercise of the inventive faculty as distinguished from mere mechanical skill to produce the Packard burner. Upon the question of infringement I have no doubt. Decree for Complainants.

The matter of electric gas lighting has been the subject of litigation for years. Two years ago A. L. Bogart, of this city, and the Electric Gas Lighting Co., of Boston, became joint owners of the patents in litigation, and proceeded jointly against all infringers. The above decision is the result. Preliminary notice will, we are informed, be served at once. As the matter now stands, only the above two concerns can manufacture these goods, and there is one licensee, who is also authorized to manufacture. It has now been established that electric hand-lighting gas-burners, having a fixed electrode, a ratchet upon the valve-stem, whose teeth are proportioned in number to the ways in the cock, and an angle-lever fitted loosely upon the stem, one arm for operating, and the other carying an electric contact point past the burner tip, a pawl attached to the lever and engaging with the ratchet, a spring to retract the lever when released and a stop-pin, and electric hand-lighting gas-burners having other equivalent devices for opening and closing the gas passage at each alternate movement, and conjointly igniting the gas by an electric spark thus generated, with further devices which, without actuating the gas-cock, shall repeat the electrical spark by the return of the opening devices to their normal position, are protected by letters patent.

ERECTING POLES WITHOUT CONSENT.

CITY OF NEWPORT, O. *vs.* NEWPORT LIGHT CO.

THE Court of Appeals has refused the Newport Light Company's motion for a re-hearing in the case of the city of Newport against it. This is a case where the light company erected electric light poles on the streets without obtaining the consent of the City Council, and the latter undertook to remove the same, when they were enjoined. The case was tried, and resulted in a verdict for the city. An appeal was taken, and the verdict sustained, and the above order ends the matter. Whether or not the city will now order the poles to be removed, is a question to be settled by Council.

EXCLUSIVE STREET RAILWAY RIGHTS.

AUGUSTA AND SUMMERVILLE STREET R. R. CO. *vs.* AUGUSTA, GA., STREET RAILWAY.

THE Augusta and Summerville Street Railroad company, of Augusta, Ga., claimed the exclusive right to all the streets for railway purposes under its charter from the legislature, and the ordinances and contracts with the city, and applied for an injunction to restrain the Augusta Street Railway company from building its electric road. The court held, without deciding the question of exclusive rights, that even if such existed they were applicable only to a street railway operated by animal power, and had no relevancy whatever to one operated by motor power, since the latter had been discovered and introduced subsequent to the date of the charter, ordinances and contract. The latter company has now in process of construction fifteen miles of electric road in the city and suburbs.

INVENTORS' RECORD

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued April 29, 1890.

Conductors, Conduits and Insulators:—*Method of Introducing Compositions into Electric Conductors*, D. Brooks, Jr., 427,039. *Electric Conductor Support and Protector*, E. M. Boynton, 427,221. *Electric Conduit*, G. Sprague, 427,445.

Distribution:—*Electrical Transmission of Power*, R. M. Hunter, 427,515.

Dynamos and Motors:—*Regulator for Dynamos*, W. H. Elkins, 427,163 and 427,164. *Commutator for Electric Motors*, A. A. Ingraham, 427,235. *Electrical Collecting Device*, G. Forbes, 427,259. *Dynamo Electric Machine*, DeW. B. Brace, 427,294. *Iron Core for Dynamo Electric Machines*, M. Deprez, 427,405. *Electric Motor*, L. Duncan, 427,503. *Electric Current Regulator*, E. P. Warner, 427,530.

Lamps and Appurtenances:—*Arc Lamp Attachment*, A. P. Seymour, 427,195.

Measurement:—*Alternate-Current Electric Meter*, G. Westinghouse, Jr., 427,489.

Medical and Surgical:—*Electric Dental Plugger*, W. E. Gibbs, 427,070. *Electric Galvanic Belt*, A. Dow, 427,468.

Metal Working:—*Method of and Apparatus for Making Rolled Forgings by Electricity*, G. D. Burton, 427,151.

Miscellaneous:—*Regulator or Rheostat*. Foree Bain, 427,082. *Magneto-Electric Machine*, C. E. Scribner, 427,122. *Electric Loop Switch*, C. E. Scribner, 427,123. *Apparatus for Testing Electric Lines*, B. E. Waters, 427,208. *Automatic Electric Switch*, M. A. Kissell, 427,237. *Gramophone*, W. Suess, 427,279. *Electric Locking Attachment*, H. J. Meyers, 427,341. *Electro-plating Bath for Copper*, 427,513. *Electric Switch*, O. S. Platt, 427,521, 427,522 and 427,523.

Railways and Appliances:—*Electrical Train-Signal*, G. D. Burton, 427,042. *Electric Connection for Brake-Hose*, W. F. Wamsley and T. McIntosh, 427,188. *Trolley*, W. F. Lewis, 427,333. *Power Transmitter for Railway Signals*, 427,361. *Railway Signaling Apparatus*, H. D. Winton, 427,387. *Electric Signaling System and Apparatus for Railroads*, C. H. Koyl and J. W. Lattig, 427,429 and 427,430. *Device for Unloading, Re-charging and Re-loading Electric Car Batteries*, J. C. Chamberlain, 427,459.

Telephones and Apparatus:—*Multiple Switch-Board for Telephone Exchanges*, M. G. Kellogg, 427,087. *Test-Circuit for Multiple Switch Boards*, C. E. Scribner, 427,120. *Divided Multiple Switch-Board*, J. J. Carty, 427,154. *Multiple Switch-Board Apparatus*, J. J. Carty, 427,155. *Telephone Exchange Apparatus*, J. J. Carty, 427,156. *Telephone*, J. C. H. Stut, 427,204.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"AT THE SIGN OF THE CLOCK."

In order to secure more room for their rapidly growing business in this city, the American Electrical Works, of Providence, R. I., have removed from 16 and 18 Cortlandt street, and have taken the first floor at No. 10 Cortlandt, "at the sign of the clock," immediately above the quarters of the Waterbury Clock Co. Mr. Phillips and Mr. Ackerman have been busy the last few days in getting things into shape, and the result is that they have laid out and fitted up a most comfortable and convenient range of offices. One feature of advantage, moreover, is that good elevator accommodation for the handling of wire packages in bulk is secured. The main offices and show room are in front, nicely fitted up in light woods. A cosy private office, whose walls are graced with pictures of successive clambake groups, is at the rear, and immediately behind that is a large store room capable of carrying a varied stock of all the excellent specialties and standard goods manufactured by the works. It may be mentioned that Messrs. F. W. Harrington and H. W. Bates have secured quarters for the Tropical Telephone Company on the same floor, thus constituting, in fact, another electrical centre in Cortlandt street.

President Phillips, while in town last week spoke very hopefully not only of home trade, but of the business that is being developed by the branch company in Canada. The results already obtained in Canada transcend his expectations, and the outlook is bright. The foundations of the enterprise have been made solid, and Mr. Phillips is more than satisfied with the magnitude and promise of the growing superstructure.

THE LITOFUGE BOILER CLEANING COMPOUND.

By this time, most superintendents of electric light and power stations have learned the desirability of keeping the boilers free from scale and the necessity of removing scale in case any should have formed; and the result is that an active demand has sprung up for boiler cleansing substances. A specialty that has lately attracted great attention in this line in America, is "Litofuge" made by the Litofuge Manufacturing Co., of 62 John street, this city. The Litofuge compounds are in the shape of an impalpable vegetable powder, and are distinguished by containing no fatty matter, acids, or chemical elements that might not only clean the boiler but in time leave no boiler to clean. These compounds are known as A. B. and C., and are disincrustant, anti-incrustant, and anti-galvanic. The first, of course, remedies the harm already done, by removing scale; the second prevents the formation of scale in new or clean boilers and the third protects boilers from the electrical action caused by the juxtaposition of iron and copper in their construction.

The proof of every compound, however, like that of every pudding, is in the eating; and the Litofuge company are in possession of many testimonials that go to show the "eating" qualities of the compound where scale and impurities held in solution are concerned. The following is one of the most recent:—

NEW YORK, April 30, 1890.

THE LITOFUGE MANUFACTURING CO.,
New York City.

Gentlemen:—

During the past year while superintendent of the Spanish American Light and Power Co., in the city of Havana, Cuba, whose electric plant consists of 4,500 incandescent lamps and 600 arcs with four 150 h. p. Hazelton boilers, I noticed that owing to the water in that city used for the boilers containing a large per cent. of magnesia and other substances, I was much troubled with the scale that formed in tubes and on plates, causing considerable expense for labor to clean the boilers, as well as deterioration of the boiler metal.

Since using your compounds, both A. and B., the result has been very satisfactory. The boilers now simply require washing, and the mud is taken out in the usual way. I made careful examination of the plates to see if they had pitted in any way, but could detect not the slightest ill effect.

I shall not hesitate in recommending your compounds where water is at all impure.

Yours very truly,
WILFRED H. FLEMING,
Member Am. Inst. Elec. Engrs.

Mr. Fleming has had considerable experience in engineering and electric light plants, and a long familiarity with the difficulties attendant upon station work. His testimony carries with it great weight.

NEW THOMSON-HOUSTON PLANTS.

The Chicago office of the Thomson-Houston Electric Co. sends us the following list of April sales:—

Arc. Illinois Steel Co., Bay View, Wis., 35 lights; Oakland Gas, Light & Heat Co., Oakland, Cal., 35 lights; Chicago Arc-Light & Power Co., Chicago, Ill., 50 lights; Capital Gas Co., Sacramento, Cal., 50 lights; Badger Electric Co., Racine, Wis, 50 lights; Terre Haute Electric Light & Power Co., Terre Haute, Ind., 50 lights; Aurora Electric Light & Power Co., Aurora, Ill., 35 lights; City of Chicago, Chicago, Ill., 70 lights; C. C. Travis, Tecumseh, Mich., 50 lights; New Omaha T.-H. Electric Co., Omaha, Neb., 50 lights.

Incandescent. Illinois Steel Co., Bay View, Wis., 50 lights; Standard Stamping Co., St. Louis, Mo., 250 lights; Denver Electric Illuminating Co., Denver, Colo., 650 lights; Marysville Electric Light Co., Marysville, Cal., 650 lights; Camden Electric Light & Power Co., Camden, Ark., 650 lights; Geo. Merritt & Co., Indianapolis, Ind., 100 lights; Swanton & Clark, Santa Cruz, Cal., 650 lights; Salt Lake Power, Light & Heating Co., Salt Lake City, Utah, 2,600 lights; C. C. Travis, Tecumseh, Mich., 650 lights.

WESTINGHOUSE WORK AND PLANTS.

We are in receipt of the following items of news from the Westinghouse Electric Co.:

Westinghouse alternating current apparatus for central station plants of a capacity of five hundred incandescent lights has been contracted for by a company which has been organized at Windsor Locks, Conn.

The Westinghouse Electric Company is highly elated at the reception its Shallenberger meter is receiving at the hands of the central station companies using the Westinghouse alternate current system. Ever since the meter was placed on the market its sale has been going steadily along. During the month of April meters to the capacity of almost fifty thousand lights were sold.

The Tesla motor is now to be introduced in the coal mines of the State of New York. The management of the Shawmut coal mines has just made a contract with the Westinghouse Electric Company for seven of these alternate current motors and one thirty horse power generator, this apparatus to be used in connection with the Hercules mining machine.

The electric light is constantly growing in popularity in the city of Elmira, N. Y. The illuminating company of that place, which commenced operations less than a year ago, has since that time been obliged to twice increase its capacity owing to the great demand made upon the light. The Westinghouse Electric Co., whose system of alternating current apparatus has been in use there from the first, received the third contract from the Elmira Illuminating Company a few days ago, and the company has now a capacity of twenty-two hundred and fifty lights.

It will not be long before from the cliffs of the island of Vancouver the electric light will shed its brilliant gleams upon the shimmering surface of the Pacific ocean. According to intelligence received a few days ago an electric light company has been organized at Vancouver, B. C , for the purpose of lighting up the city. The Westinghouse alternate current apparatus for central station plants has been contracted for by the Vancouver company.

Along with the other improvements which the Pennsylvania Railroad Company has inaugurated at Altoona, Pa., is to be added an arc light plant of ninety lights. An examination into the different existing systems of that mode of illumination decided the company to use the new Westinghouse arc light system, and the machinery will be immediately installed.

SMALL EDISON LAMPS.

The Edison Lamp Co. of Harrison, N. J., have just issued in "Catalogue E" a most interesting little pamphlet on the uses of their small lamps. In fact it is not simply a trade circular or price list but rises to the dignity of an instructive treatise on the subject. The value and the beauty of the small incandescent lamp have never yet been fully appreciated, and there remain many fields of ornament and utility in which it should find extensive employment. The pamphlet includes a section on batteries, and gives also some eminently practical instructions with regard to the manner of making a cheap "tumbler" cell, using "National" carbon pencils as carbons, so that singly or together they will maintain a lamp at full candle power for two or three hours. This simple battery is clearly illustrated. Cuts are also given of lamps for regular lighting circuits. At the end is a price list of the lamps, with cuts of the actual size, and a list of the agents and dealers from whom they can be obtained. On the covers is a long list of the Edison patents on incandescent lamps. The pamphlet is likely to have a very marked effect in stimulating the demand for such lamps, and we recommend our readers to secure a copy at once.

PARVIN'S LISTS.

S. H. Parvin's Sons, the well known newspaper advertising agents of Cincinnati, have sent us a copy of their new revised list of mechanical, trade and industrial papers. It comprises a number of prominent journals, and gives their size, time of publication, circulation, &c. There is furnished also a list of several of the manufacturing concerns who place their advertising through the Parvin agency.

C. C. SIBLEY & CO.

Messrs C. C. Sibley & Co. of 416-418 West 26th Street, this city, have completely equipped their new factory with the latest improved machinery and are now manufacturing electric lamps, motors, and general railway, telegraph, and other electrical supplies. They make a specialty of manufacturing for the wholesale and jobbing trade and dealers. Inventors just introducing their specialty will do well to correspond with them. Mr. C. C. Sibley has been actively engaged in electric manufacturing for several years past, and being seconded by Mr. F. G. Jahn, M. E., who is an expert in electrical matters, he purposes to do only the highest grade of work, at moderate prices. They are a pushing young concern and undoubtedly will succeed in whatever they guarantee or put themselves at.

THE NORTH AMERICAN CONSTRUCTION CO.

The North American Construction Co. of Pittsburgh has just completed the wiring of the new theatre at Worcester, 574 lamps having been installed. Mr. H. C. Hawks, the New England manager, has endeavered to make this a model theatre plant, and has every reason to feel satisfied with the results of his labor. Simplex braided caoutchouc wire has been used throughout, partly on insulators, and part being run through conduit tubing. The circuits were so arranged as to bring them to the back of the stage near the switch-board in easy reach of the attendant. The switch-board is of slate, and directly beneath are the handles by which to manipulate the Westinghouse stage regulators which are placed in the basement, thus taking up for electrical apparatus a minimum amount of space on the stage floor. Red, white and blue lights have been provided for the stage, and there are eight movable clusters of five lights with reflectors, for throwing light on the stage from the side. In order to make the plant as safe as possible the Westinghouse converters have all been placed in a fire-proof chamber in the basement. The current is supplied by the local company, and at the opening night the lights were turned on with brilliant effect, and complete success.

JAS. J. MURRAY & CO.

A representative of The Electrical Engineer had the pleasure, some days ago, of making a tour of inspection through the extensive glass works of Jas. J. Murray & Co., Philadelphia. This house manufactures and fills orders for arc and incandescent globes and shades in endless variety of size, shade and finish, besides keeping a large warehouse stocked with the principal sizes. It is truly wonderful to follow glass through the various stages of its manufacture from a canal boat load of sand, a car load of oil for fuel, a generous supply of water for steam, and a bucket of acid, to the incandescent shade etched with a dainty delicacy suggestive of lace.

Arc light globes of all descriptions and sizes are kept constantly in stock, and electric light companies are more and more appreciating the promptness with which their orders are filled and the merits of the goods themselves.

BALL ENGINES.

Owing to the growing demand for their engines, the Ball Engine Company, of Erie, Pa., have been obliged to increase their facilities and they are now building a foundry and moulding room.

DYER & SEELY.

This well known firm of practitioners, who have charge of so much of the Edison patent litigation business, have removed their offices from 40 Wall street to 36 Wall street. The firm is composed of R. N. Dyer, H. W. Seely, D. H.Driscoll and C. M. Catlin.

ST. LOUIS TRADE NOTES.

J. A. McClure has been appointed superintendent of motive power of the Lindell Railway, St. Louis.

Parrish Brothers and the Peck Electrical Company have opened an office in connection with the Southern Electrical Co. at 823 Locust St., St. Louis. Mr. D. L. Skidmore is in charge as agent.

The Interstate Gas and Water Works Company of St. Louis have filed official notice in the Recorder's office that they are about to extend their business, so as to include the erection, management and maintenance of electric light plants.

Mr. Charles Heisler, inventor of the long-distance system of incandescent lighting, has gone to Germany to rejoin his family. His daughter is to be married during this month to Herr Rudolph Buhl, a leading manufacturer of Edlinger, Grossherzogthum Baden. Mr. Heisler is expected to return in the fall.

NEW ENGLAND TRADE NOTES.

The Taunton Locomotive Works, of Taunton, Mass., have received orders from the West End Street Railway Company, of Boston, for 30 swivel trucks of a special design, to be used under the new long open cars, which are being built for the summer travel on the electric lines.

Johns-Pratt Co.—A factory for the manufacture of electrical insulators is to be erected by the Johns-Pratt Company at Hartford, Conn., and a second building has also been begun. The main structure will be a two-story brick building, 140 feet long on Capitol avenue and 40 feet wide. The other building, in the rear of the first, will be of brick, 90 feet long, 40 feet wide and three stories high. There will also be an engine and boiler house. Both buildings will be finished inside with Southern pine. Both buildings will be fitted up with electric lights throughout.

NEW ENGLAND TRADE NOTES.

Mr. Simeon E. King, assistant secretary of the Worcester Mutual Insurance Company (one of the Factory Mutuals), will temporarily take Mr. H. H. Fairbanks's place as secretary of the Electric Mutual Insurance Company.

The Electical Safety Company, formed to sell the Cartwright Protector, have sold their New England patent rights to the New England Electrical Safety Company, which will use the same offices in the meantime as the parent company. Mr. Hiram Simmons is president, Mr. C. F. Atherton, lately connected with the Thomson-Houston Electric Company, is treasurer and secretary, while these two gentlemen, with Mr. Mark Hollingsworth, will form the board of directors. The parent company retains the right to manufacture the protectors.

THE INTER-CONTINENTAL TELEPHONE CO.

The Inter-Continental Telephone Co. has sold all its rights, concessions, good-will and business in Venezuela to a very strong syndicate of English, Amsterdam and French capitalists for £30,000 as a going concern, with 1,250 subscribers, earning, all told, 7% net on $200,000, its full capital. The concession and business has been transferred with the approval of the Venezuela Government, and the new company undertake to extend the business throughout the country, and for that purpose have taken over the Tropical Telephone Co.'s contract, and already have expended about £6,000 for new instruments, switch-boards and line supplies, and stand ready to expend £4,000 or £5,000 more at once.

The Inter-Continental Telephone Co. received its original concession in 1883, which was approved by Congress and which was signed by President Guzman Blanco. A provision in the contract being that no similar concession would be granted to any other company. There are besides several later concessions and contracts made by the Government which cannot be annulled except by Congress. In the meantime, however, the Government of Venezuela did give concessions to the American Telephone Company consolidated, which sent representatives to that country, secured a few subscribers, and raised a large amount of capital in this country to push the business. This company was, however, effectually broken up by the Inter-Continental Company, and all the stock of the company was returned to the subscribers. The Inter-Continental Company, having now sold their rights to the English, it is safe to say that the Government will grant no more concessions to rival companies. "John Bull" will effectually protect his own rights, especially as there is already a large amount of English capital invested in Venezuela.

THE SPRAGUE PHILADELPHIA OFFICE.

We are advised by the Sprague Electric Railway and Motor Company, that they have temporarily discontinued their Philadelphia office, and that all business will hereafter, until further notice, be conducted directly from their New York Office at 16 and 18 Broad street.

THE GETHINS IMPROVED GRAVITY BATTERY.

The Gethins Electrical Manufacturing Company have issued a very interesting pamphlet on their improved gravity battery, which shows very clearly and conclusively the advantages to be gained by their method of dividing the two liquids into horizontal layers by their specially prepared porous cup. The Gethins battery continues to meet with the most pronounced success, and the company is recently in receipt of the following unsolicited testimonial, which speaks for itself :—

Police Department of the City of Boston,
Signal Service Office, A Pemberton Square.
April 17, 1890.

To the Hon., the Board of Police Commissioners :—

Gentlemen :—I herewith report that the Gethins Gravity Batteries placed in Station 10, Jan. 17th, 1889, were recharged with new elements of the same kind April 4th, 1890, having shown a constant service of 14 months, 18 days. As the service of a battery is in proportion to the work done, I would state that during that time there were received 2,857 wagon signals, 12,237 telephone signals and 198,486 "on duty" signals. As each signal will average 10 breaks of the current, this would indicate an armature movement of 2,131,160 times. As compared with the standard crow-foot battery, the best record in this service is 7 months, 23 days.

Respectfully submitted,
[Signed.] Henry A. Chase, Electrician.

NEW ENGLAND TRADE NOTES.

The Jordan Train Lighting Company has secured control of the Duralite Manufacturing Company, whose offices are at 85 Water street, Boston. Duralite is a wood pulp, or paper fibre, and can be made either fireproof or waterproof, or both, if necessary. It can be moulded into any desired shape, and is an excellent material for lamp sockets, buttons or any insulating piece of electrical apparatus. It will take a very high degree of finish, and comes out of the moulds with a beautiful glossy surface, as if polished. The Jordan Train Lighting Company will go into general electric construction work, comprising electric light and power construction, bells and burglar alarm work, and will carry a full line of electrical supplies. Among their specialties will be the Jordan mast arm, the Jordan train lighting apparatus and the Jordan automatic trolley-arm.

The Gould-Watson Company are in receipt of very large orders from all parts of the country for their well known moulded mica insulators, which can be made both water and fireproof. They have just completed arrangements to furnish insulators complete, with all the necessary metal fittings, so that electric companies can be supplied without having to send the castings to fit into the insulating compound. There continues to be a brisk enquiry for their goods from London and other European cities. Gould & Watson are also supplying large quantities of imported mica for all electrical purposes.

P. A. DOWD & CO.

The above firm, local agents for the Sprague Co., have closed a contract with the Newark Rapid Transit Co. for 16 cars and four 80,000 watt dynamos. They have also closed a contract for the Troy and Lansingburg Street Railway, for 10 open car equipments.

WESTERN TRADE NOTES.

The Illinois Anglo-American Storage Battery Co., who handle the well-known Sorley storage cells in the West, have removed their office from their old quarters, at 95 Dearborn street, to 177 La Salle street. Mr. W. D. McDonald is the manager of the company.

The Mather Electric Co. of Manchester, Conn., have obtained the contract for installing an incandescent plant in Hamsah & Hagg's new building in Chicago. This contract was carried off by the Mather people after a long and hard fight.

The Pumpelly Electric Storage Battery & Motor Co. have just installed a storage battery plant in Delavan, Wis.

The National Engineering Bureau, although of very recent organization, are getting lots of business and making tests and reports all the time. They make a specialty of this class of work, for which there is a large and continually increasing field.

Electric Watches. The latest novelty in outside watch signs for jewelers is the addition of electrically operated works placed in the interior of the old-time watch dummy. One cell of primary battery is employed, and the signs are made in large or small sizes and have a very striking and unique appearance. This device was got up by Mr. L. S. Grout, of 126 Dearborn street, Chicago, who is turning them out in large numbers.

Mr. William Hood, the Western agent of the Electrical Accumulator Co., of New York and the Electro Dynamic Co., of Philadelphia, has made arrangements to handle the new Walker meter, which was described very fully in our columns recently. This sensitive and delicate instrument registers by means of a photographic record and thereby attains remarkable accuracy.

Mr. Huntington Lee, of the Fred. H. Whipple Co., of Detroit, who is now in Chicago looking after the business of his house, was a caller at this office. He is particularly busy in making arrangements for the coming electrical exhibition at St. Louis, of which Mr. Fred. H. Whipple is the general manager. Mr. Lee will assist him and take charge of the construction work and in such hands the work will be carried out with credit to all concerned.

The Excelsior Electric Co., who have been located at 11 East Adams street have, owing to the rapid and constant increase in their business, been compelled to secure new and more commodious quarters in the Rookery Building. This is fast becoming Chicago's electrical centre, and already numbers many of the prominent electrical companies among its tenants.

Visitors at the Chicago Electric Club last week were Mr. G. M. Peters, Cincinnati; T. B. Brown, Kansas City; C. M. Peck, Cincinnati; W. H. Lukins, Streator, Ill.; W. H. Gillett, New York; Ely E. Ware and Charles Ware, Cedar Rapids; E. D. Stiles, W. A. Stiles, A. K. Stiles, Chicago; Jas. F. Cummings, New York, who is interested in a large Edison plant which is to be installed in Milwaukee right away.

The Hawkeye Electric M'f'g Co. of Davenport, Iowa, have installed 11 of their motors in St. Joseph. The latest put in is one of 10 h. p. capacity, at John Armstrong's coffee house on Edmond street. The Union Railway Co. is furnishing the necessary power.

Mr. Geo. E. Clow, 57 S. Jefferson street, Chicago, is making a specialty of cut-outs and switches for electrical purposes and turns out some very fine work. He has recently increased his facilities and is now able to cope with any quantity of business in the line. He puts the finest mechanical workmanship throughout into his goods, and is enjoying a well earned reputation thereby.

"Electrical Industries."—Our esteemed contemporary, *Electrical Industries*, has removed its offices in the Rookery, which were located in room 304, to more comfortable quarters in room 351, in the same building. They now have very handsome and convenient quarters and considerably more floor space than before.

Mr. Frank B. Rae, the electrical engineer of the Detroit Electrical Works, was in Chicago for several days last week, and devoted all his available spare time to the Club and the clubmen.

Mr. W. A. Jackson, manager of the Michigan Telephone Co., was a visitor at the Club on Saturday.

Mr. M. A. Knapp, the manager of the Knapp Electrical Works, has gone east on a business trip and expects to be away from the city for about a week. He will visit Detroit, Pittsburgh, Hartford and New York.

THE
ELECTRICAL ENGINEER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. IX. NEW YORK, MAY 21, 1890. No. 107

The great development in electricity will be, I am firmly convinced, in discovering a more economical process of producing it.—T. A. Edison.

POWER PROFIT vs. LIGHT PROFIT.

IT is not at all unlikely that some of our central station readers have sat down now and then and tried to figure out for themselves the different returns obtainable from current sold as light and current sold as power; but we are, nevertheless, inclined to believe that local lighting companies as a rule have not yet begun to treat the power question as it deserves, taking it up seriously and giving the electric motor a fair trial, as the basis of a large and legitimate business.

While we would be the last to disparage the excellence of the opportunities presented by electric lighting as an industry, we do not hesitate to express our conviction that electric power is, if anything, superior to it, as productive of a return upon the capital invested and the care required. Where the two industries are intelligently conjoined in the one plant, the superintendent may rightfully feel that he is making the most of his chances—but not till then.

Let a station superintendent who has never done so before give a spare hour. or two to an inquiry into the amount of power used within the area covered by his circuits, as well as the amount he could dispose of if people knew that his motors were available. He will be surprised at the result. The aggregate of elevators, sewing machine gangs, coffee mills, ventilating fans, ice cream freezers, printing presses, and other apparatus needing power through the day and night would prove respectable enough to warrant the running of a power circuit in any place above the level of a village, and blessed with a good central station.

Let the superintendent also, during the spare hour that we have so freely assumed him to have at his disposal, make a little calculation as to what the current will bring him in per horse power in light, and per horse power in mechanical energy. Thus, for example, say he is getting $100 per year for a full arc light. Against that he has to charge in the neighborhood of $10 for carbons, and the services of the trimmer, as well as breakage of globes, etc. How much will he get for the same horse power in motor service, less the charge for carbons and with certainly a much lower charge for attendance? The calculation on the basis of either arc lighting or incandescent lighting is well worth making, it being borne in mind that with the power subdivided in small motor units, the very fullest generating capacity of the plant can be sold.

And then there is the question of street car operation. Why should a superintendent whose blood is warm within him, sit still and see the street railroad in his town plod along with horses, when he can supply current for a modern electric service that will stimulate, and boom, and brighten up every interest in the locality? Here again let the calculation as between power and light be made, with the idea of exacting from the station investment the best return of which it is capable. We do not think the hesitation to occupy the field would last very long.

FURTHER EDISON CONSOLIDATIONS.

IF the rumors that are faintly heard as we go to press be true, and there seems good reason for entertaining them as pretty nearly correct, considerable changes will shortly be made in the management of the vast Edison manufacturing interests. It will be remembered that when the Edison consolidation was effected about a year ago, the intention was to have all the manufacturing and sales departments under one control, and it would appear that the new programme simply develops that plan to its natural conclusion, rounding out the whole scheme of organization. The reports to which we refer go so far as to associate the name of Mr. Samuel Insull, who has long been actively engaged in the direction of the Edison Machine Works and other branches, with the oversight or management of the whole new amalgamated department, and it certainly would not be very surprising if he were selected. While we cannot say that we have been able to confirm these rumors in their entirety, the signs are that they hit near the mark, and we give them for what they are worth. Probably in a week or two, further news will be obtainable with regard to this notable change of such great importance, a change which, if we do not misunderstand it, means that the Edison General Electric Company will, in its own name, direct and control from its headquarters in New York, all the Edison manufacturing and sales interests now scattered throughout the country under a variety of titles.

THE CARBON BRUSH.

IN the early days of the dynamo and motor when the magnetic proportions of armature and field were not so well understood as they are to-day, the trouble caused at the commutator was of frequent occurrence, and to such an extent even that not a few set about devising means for avoiding its use altogether. Though this difficulty disappeared in a great measure in later and more correctly designed dynamo-electric machinery, its removal may be said to have been entirely accomplished by the application of the carbon brush in the stead of the copper strips. Indeed, looking at it from our present standpoint, and more especially with reference to electric railway work, there is hardly one detail which has contributed more to the successful operation of the electric motor than this. While the importance of this improvement may not be so apparent in its application to stationary apparatus, which can be inspected and regulated at any time, it assumes immediate prominence when applied to a motor under a car, subject to every adverse condition of operation. We are led to these observations by the recent issuance of a broad patent covering the use of the carbon brush which has just been granted to Prof. George Forbes, of London, and which, in view of the extended application of the carbon brush at the present time may be looked forward to as the basis of probable future litigation. We print the claims elsewhere. We publish in this issue also the description of a type of carbon brush due to Mr. Leo Daft, in which the heat resisting and wearing qualities of carbon are enhanced by the addition of plumbago as a lubricant. The success which has thus far attended the employment of the carbon brush on street railway motors makes it fair to assume that it will in time find general employment in stationary work also, and that further improvement may be looked for.

ALTERNATING CURRENTS AT HOME AND ABROAD.

We print elsewhere an extract from an interesting letter by Mr. R. E. Crompton, which throws considerable light on the differences which exist in the application of the alternating current in this country and abroad, and more especially in England. Mr. Crompton has recently installed an alternating current plant after having been, and still continuing to be, a strong advocate of low-tension distribution in conjunction with storage batteries. He shows the reasons for his action, which coincide with what may now be said to be the general opinion of competent electrical engineers. Lighting abroad is confined principally to private dwellings, in densely populated districts, and where as a rule a single dwelling is normally burning but few lights it is wired for a large number, which may be required at more or less frequent intervals, and in which converters would for a large part of the time be working at a very light load. Mr. Crompton also points out the interesting fact which is sometimes lost sight of, that under the conditions imposed, the cost of the underground system in London is almost independent of the weight of the copper conductors, which are only a small percentage of the whole outlay. Mr. Crompton admits, however, that where the lighting is scattered the alternating system has many advantages, especially where overhead conductors can be employed. The consistency of Mr. Crompton's action is therefore apparent, and he proves that the success attained by him in his Kensington and Knightsbridge districts in London in connection with storage batteries has left him unbiassed where the conditions of distribution are different from those obtaining there.

COPPER IN THE TARIFF DEBATE.

Mr. Butterworth, of Ohio, treated the House and the country to a sensation, May 13, by a ringing speech in the tariff debate, attacking the McKinley bill in the house of its friends and promoters, forcibly exposing its inconsistencies and its humbug as a measure of tariff reform, from the point of view of an earnest protectionist. Illustrations of these qualities, in plenty, were ready to his hand in the text of the bill, and he made good use of them. Among them was the copper schedule. The McKinley bill would reduce the duty on ingot copper from four cents per pound to two cents, and leave untouched the duties of thirty-five per cent. on plates, sheets and rods, and forty-five per cent. on wire. Mr. Butterworth said:

> Will you tell why the duty on copper should be continued? Why not make copper free to all the people who are using it in this country? Do you not know that every electrician in this country petitions to remove the duty on copper? Is it necessary to protect this industry? Is it an infant industry?
>
> * * * * * * * * * * * *
>
> There is no apology in the world for the duty, not the slightest. It does not protect any industry, but it draws on every family we represent. There is not a yard of wire, not a piece of copper in any household in the land that does not pay tribute. * * *

Mr. Butterworth's strictures were mainly directed to the duty on ingot copper and its abuse by the copper mining companies. After pointing out that American copper had usually been sold in foreign markets at lower prices than in our own markets, he continued:

> Nor is that all, Mr. Chairman, but having control of the copper market in 1887, they organized a combine by which the supply of American copper had to go back to American homes, sifted through the mercies of a French syndicate.

Mr. Cannon, of Illinois, entered the discussion to express his belief that no necessity existed for a tariff on copper. In the course of his remarks he recited an incident that indicates the motive of the copper men in seeking to retain a duty on ingots. Said Mr. Cannon:

> I said to a man who has great copper interests, but yesterday, when he said that he himself had suggested the cut on copper one-half from the present law: "But why not carry it further and cut it all?" He said frankly: "I think that it could be done, but conditions might arise in the future where it would be embarrassing to the industry."

There's where the rub comes. Free copper might easily be embarrassing to the promoters of combinations for restricting competition and keeping up prices. It is not easy to conceive how it could otherwise "embarrass the industry" while this country produces a surplus of copper for export, and while we have the word of leading mine owners that they can produce the best metal in the world and lay it down in New York at 6 to 7 cents per pound.

The Washington Navy Yard Plant.

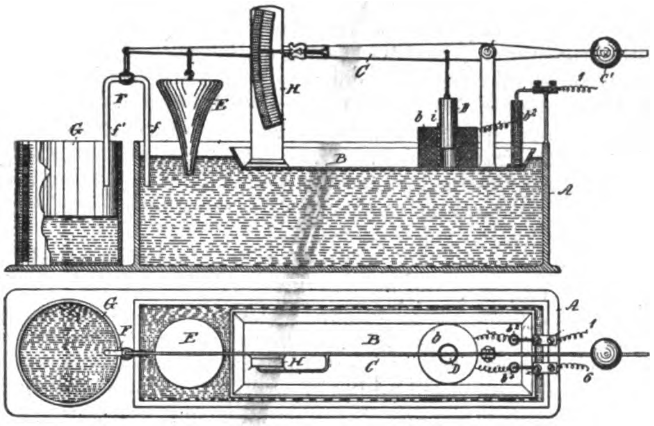
The high standard of excellence and efficiency set by the United States Naval authorities in electrical work is familiar to our readers, some of whom may be excused for thinking that now and then the requirements have been a little too exacting. Still there is a pleasure in seeing the standard maintained, and we are glad to be able to illustrate this week the beautiful Brush plant installed at the Washington Navy Yard, where it has met the most onerous conditions with perfect satisfaction. Aside from being a model of its kind, the plant is also interesting as the first shore installation put in for the Navy. We invite attention to Ensign Wilkes' careful article, and venture to express the hope that such plants may speedily multiply.

CURRIE'S ELECTRIC METER.

The general demand for electric meters has resulted in the designing of a large number of them, depending upon a variety of principles, including the magnetic, heating and chemical actions of the electric current. That this field is not yet exhausted, however, is evidenced by a recent adaptation due to Mr. S. C. C. Currie, electrician of the United Electric Improvement Co., of Philadelphia. This novel meter embraces in its construction the action of the current upon a magnet, as usually employed for such purposes, which in turn controls the quantity of liquid passing into a vessel, so that the measure of the liquid serves as a means of determining the amount of current which has passed during a given time.

The manner in which this is effected is shown in the accompanying engraving (Figs. 1 and 2), which represent respectively a plan and section of the apparatus.

It consists essentially of a tank, A, filled with a liquid, and in which is placed a float, B. Upon the latter is mounted a solenoid, *b*, which is placed in circuit with lamps by means of wires, 1 and 6, which dip into the long mercury cups, b^2 and b^3. The lever, C, carries the core, D, which is under the influence of the solenoid, and also a float, E, which dips into the liquid. At its extreme end the lever carries a siphon, F, the two legs of which dip, respectively, into the liquid in tank, A, and into the vessel, G. There is also provided a scale by which the strength of the current passing at any time can be read off directly.



Figs. 1 and 2.—Currie's Electric Meter.

For the operation of the meter, the tank, A, and the tube, F, are filled with a liquid, such as acidulated water, and the oscillating lever, C, is so adjusted by means of the counter-weight, c', that the end, *f*, of the siphon will extend a short distance, say one-eighth of an inch beneath the surface of the liquid in the tank, A, in which position the acidulated water will not be siphoned from the tank into the vessel, G. The tube, F, is previously filled with liquid by suction, and placed in position with the end, f', extending into the vessel, G. A tube with a very fine bore is employed because the liquid will remain in the tube even when raised entirely above the surface; and also for the reason that when one end of the tube is immersed a short distance, say a quarter of an inch, into the liquid, the latter will not flow at the opposite end; that is, of course, assuming that the two legs of the siphon are of equal length. This is due to the fact that the pressure or head is not sufficient to overcome the capillary attraction, and hence the first readings from the zero-point commence from a point slightly below the surface of the liquid. This is of considerable importance, for the reason that the tube need never be raised entirely out of the liquid, and consequently never emptied.

It will thus be seen that according to the strength of current passing through the solenoid, *b*, will the plunger, D, and consequently the tube, F, be proportionally lowered; and hence the amount of the fluid which will flow in a given time from the tank, A, through the siphon, F, into the vessel, G, will be dependent upon the current through the coil, *b*. At the same time the strength of the current flowing at any moment may be observed by the pointer on the dial.

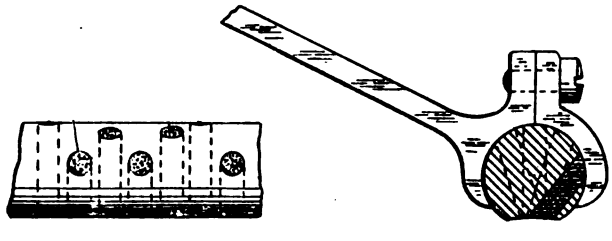
The attraction on an iron core by a solenoid will not alone cause the various depths of immersion of the siphon, F, so as to cause the flow of the liquid through the same, consequent upon the variations in the "head," to give absolute proportions, and hence, in order to obtain the desired absolute proportional results, the displacement-float, E, is suspended from the lever, C. The shape of this float is such that the resistance exerted against the downward movement of the lever by its displacement of the liquid is so proportioned at the various depths, that the immersion of the siphon, and consequently the flow of the liquid through it is exactly proportional to the amount of current passing through the solenoid.

During the operation of the meter the float, B, sinks farther into the tank, A; but the contact from the circuit through the coil, B, is maintained by means of the wires dipping into the mercury-cups b^2 and b^3. By this arrangement if by accident or neglect the water should sink below a certain level the circuit will be automatically broken and the lamps in the circuit extinguished.

It is evident that by measuring the quantity of water which has passed by drops from the tank, A, into the vessel, G, in a given length of time the quantity of electricity which has traversed the meter in that time may be at once ascertained. For that purpose the scale, *g*, is so graduated that the height of the water as indicated will represent the number of units of electricity that have passed through the meter in a given time.

DAFT'S CARBON BRUSH.

The great durability of carbon due to its heat resisting qualities, has led to its general adoption as a contact for commutators, especially on those employed for electric railway work. Pure carbon alone, however, while having great heat resisting properties, has but very little lubricating qualities, and hence some means of combining both qualities in one is desirable. This has been recognized by Mr. Leo Daft, who has recently devised a form of "brush" or contact which is illustrated in the accompanying engravings. It consists of compressed, ground, cemented gas-retort carbon, in which are inserted pencils of plumbago having their ends projecting at the wearing surface The surface-contact is generally ground to a circle, as shown, so as to leave a sufficiently large contact-area and permit equal pressure over all its surface, so as to prevent sparking. Instead of inserting the plumbago in pencils, the powdered plumbago may be mixed with powdered carbon, in the proportion of five to fifty per cent., using coal-tar or molasses to hold the mass together during baking. The object of this combination is to form a conductor of a substance of high conductivity and great lubricating power, so as to reduce the wear of the commutator and increase the smoothness of its operation. Where it is desirable to secure a perfectly noiseless machine for light running purposes, Mr. Daft finds it beneficial to incorporate one to two per cent., by weight, of finely powdered silicate of magnesia in addition to the plumbago.



Daft's Carbon Brush.

DR. LODGE'S LIGHTNING ARRESTER.

In our last issue we gave a description of a new form of lightning arrester devised by Dr. Oliver J. Lodge, and based on the principle that the lightning discharge is forced to jump the air gaps to earth by the interposition of inductive resistances.

We are now enabled to illustrate the actual apparatus as constructed by Dr. Alexander Muirhead. The engraving,[1] Fig. 1, shows it in perspective, and Fig. 2 is a diagram of the connections. The central boss, it will be noted, is connected to the brass case by means of a rod down the centre. Underneath, in the base of the instrument, is a screw to which a direct connection with the earth is made. The screw on the central boss at the top is only used when a handy earth is wanted for an instrument. The first projecting rod is of platinum, the second of brass, and the remaining three are of copper. This arrangement, it will be seen, is equivalent to that shown in our issue of last week, with the lower row of coils omitted.

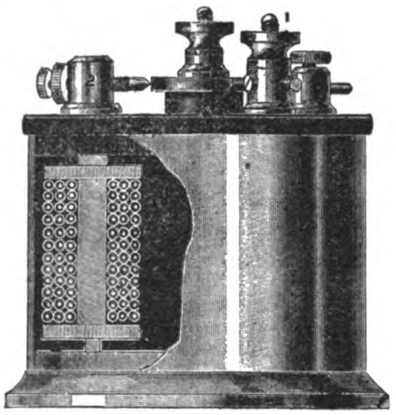


Fig. 1.—Lodge's Lightning Arrester.

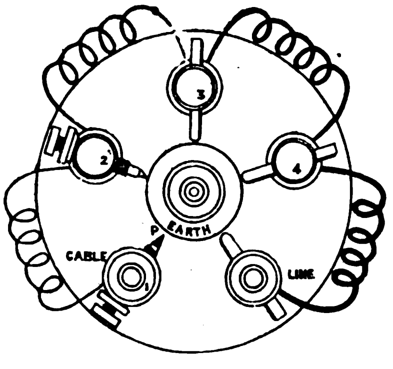

Fig. 2.—Lodge's Lightning Arrester.

The self-induction of the coils is inappreciable for ordinary currents and they contain no iron cores. The superiority of this device over ordinary single air-gap protectors, at any rate in the case of powerful discharges from a large Wimshurst machine, is said to be most marked.

RESISTANCE WIRES IMMERSED IN LIQUIDS.

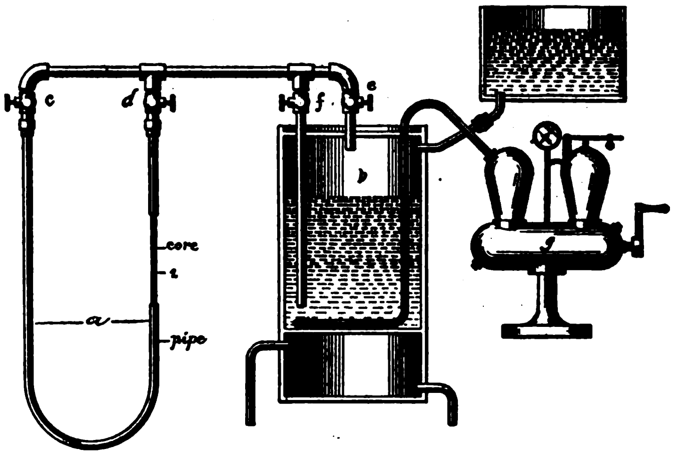
BY PROF. WM. A. ANTHONY.

In The Electrical Engineer for May 14, is a description of a rheostat constructed by Mr. Forée Bain, consisting of iron resistance wires immersed in a liquid. I constructed a rheostat of this description some twelve or fourteen years ago for use at the Cornell University for controlling currents used in electrical experiments. A rheostat constructed in this way, of course may be made of very much finer wire than one surrounded by air, but there is a difficulty met with when there is any considerable difference of potential between the different parts of the wire, and that is, the water is decomposed and the wire in that way corroded and finally destroyed by the action of the current. Finding that this was taking place, we used distilled water which worked better for a time, but even the distilled water, containing perhaps some traces of carbonic acid in solution, would, under strong currents, attack the wire, and this would of course increase its conducting power and the action would then go on more rapidly. We were obliged to give up this form of rheostat on account of the rapid destruction of the wire from this action. All this can, of course, be avoided by the use of some insulating liquid, as, for instance, some of the oils.

PATTERSON'S METHOD OF CABLE MANUFACTURE.

The extended use to which underground cables are being applied both for telegraph and telephone purposes in this country has tended to bring out prominently the effects of static capacity, and its retarding influence; and hence we find continual attempts being made to reduce this factor in cables, a seemingly small difference in this particular making, for instance, quite a large difference in the distinctness of telephonic transmission. Mr. W. R. Patterson of Chicago, who is well known in this department of work, describes in a recent patent a method of cable manufacture which embodies several novel features.

The method consists in placing the core of insulated conductors deprived of moisture within a pipe and then forcing insulating-filling into both ends of the pipe. Mr. Patterson considers a core consisting of insulated conductors thus deprived of moisture as an unsaturated core, as distinguished from such a core which has been dipped in some melted insulating substance—as, for example, hot paraffine—so as to saturate the fibrous insulating-covering of the wires. In connection with this process Mr. Patterson uses a generator of carbonic acid gas, and a charging-chamber containing the insulating filling. This apparatus is so constructed as to permit of forcing gas into the cable under a definite pressure and afterward forcing the insulating filling into the two ends of the pipe under a greater pressure, as would be necessary. The gas in the pipe will thus be compressed according to the distance to which the insulating filling is forced in.



Patterson's Method of Cable Manufacture.

The manner in which this is carried out in practice is shown in the accompanying diagrammatic view. The coil of pipe *a* is connected at each end with the reservoir *b* containing melted paraffine and gas under pressure. The cocks *c d* are both opened when the coil is being filled. First the gas-cock *e* is opened and the paraffine-cock *f* closed. The gas is then generated in the generator *g* at such pressure as is required. A pressure from seventy to eighty pounds to the square inch is found sufficient. The gas-cock *e* remaining open the coil of pipe *a* will be filled with gas and the air contained therein under the desired amount of compression. This is accomplished by shutting off the gas-cock *e* and opening the paraffine-cock *f*, and still further increasing the pressure—say up to ninety or one hundred pounds per square inch.

---

[1] London *Electrician*.

In practice the ends are filled to a distance of about twenty-five feet each, regardless of the length of the cable. After sufficient paraffine has been forced into the pipe the cocks *c d* are closed and the paraffine is allowed to cool. The reservoir *h* is designed for supplying the tank with paraffine. The paraffine thus forced in at the ends acts as an effective means for imprisoning the gas, and at the same time acts as a dam to prevent the entrance of moisture into the cable.

CHAMBERLAIN'S COMPOSITE "WAVE" PINION FOR ELECTRIC CARS.

The high speed at which electric motors are required to operate in order to secure a proper efficiency has necessitated the employment of gearing to reduce the speed of the armature shaft to that of the car axles. The noise and vibration accompanying the employment of solid gear-wheels, however, soon became apparent, and means for overcoming both were applied, which consisted in the substitution of pinions built up of alternate layers or discs of steel and a variety of substances such as raw hide, fibre, etc. These composite pinions, it is true, largely reduced the troubles formerly experienced, but they introduced others which those operating electric railways have found to be of considerable moment. These consist principally in the fact that, owing to the layers of the composite pinion being placed in planes at right angles to the axis of the shaft, the wear on the all-metal gear-wheel is confined almost wholly to the parts opposite. The result of this is that circumferential grooves are worn in the all-metal gear, which leave ridges at the parts opposite the rawhide. The wear being thus confined to a portion only of the all-metal wheel, the same is more rapidly worn away and its working life is considerably shorter than would be the case were the wear equally distributed.

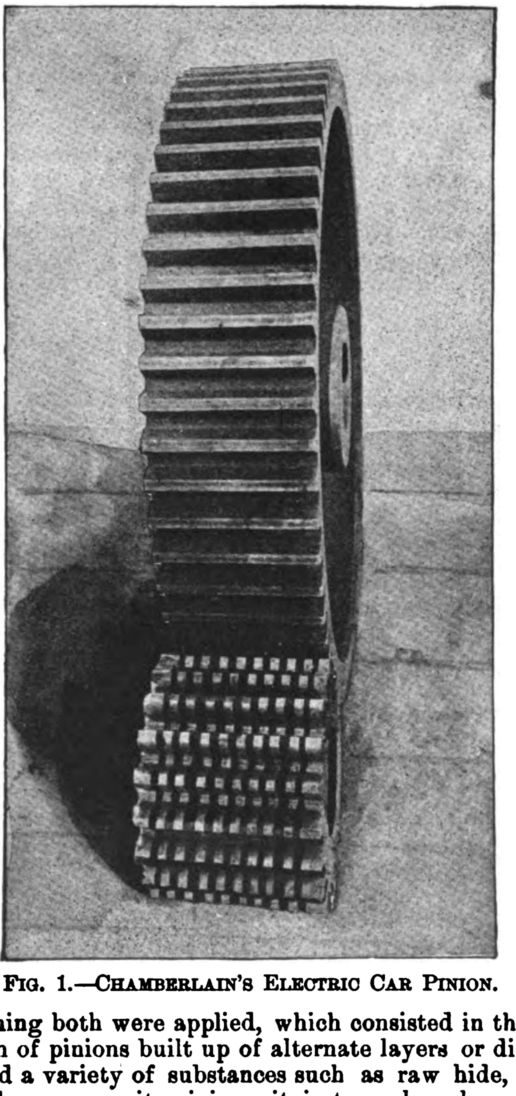


Fig. 1.—Chamberlain's Electric Car Pinion.

The exact nature of this unequal wear was well illustrated in our issue of April 23, in which was shown an engraving of a gear and pinion that had been in operation on a car which had travelled 18,000 miles.

While the non-resonant qualities of the composite gear were highly desirable, it was manifest that an improvement designed to afford an even wear of both pinion and gear was of not less importance, and this has been effected in a very simple and ingenious manner by Mr. Jacob C. Chamberlain of this city.

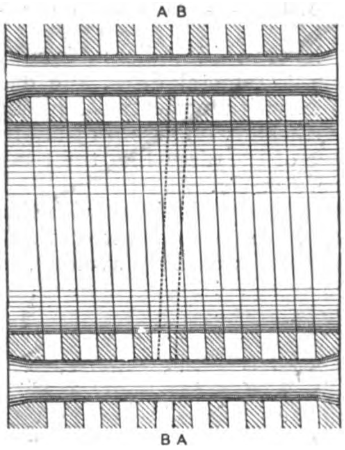

Fig. 2.—Chamberlain's Electric Car Pinion.

The desired object has been accomplished by placing the alternate layers of metal and rawhide of which the pinion is composed at a slight angle or cant to the axis of the wheel so that the metal portions in bearing on the all-metal wheel travel laterally upon the same in a worm-like or "wave" motion so as to distribute the wear.

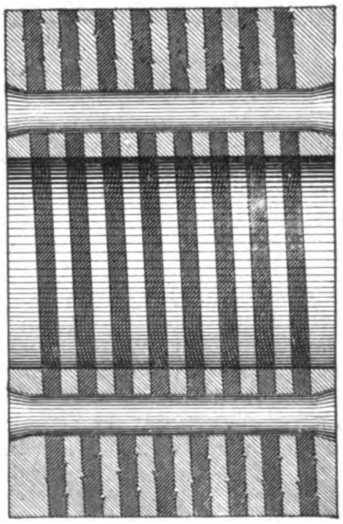

Fig. 3.—Chamberlain's Electric Car Pinion.

The pinion built up in this manner is shown in perspective in the accompanying engraving, Fig. 1, and its construction will be readily understood by an examination of the sectional drawing shown in Fig. 2. Here it will be noted the steel disc occupies the position A A at one point; during the next half-revolution, however, on account of its slant, it will have assumed the position shown in the dotted lines, B B. In other words, its periphery will have traversed a distance laterally somewhat greater than the width of the disc.

The result of this is that each tooth of a disc bears in part on a portion of the engaging wheel different from that engaged by the preceding tooth, thus shifting the wear and distributing it over the whole working face of the all-metal wheel.

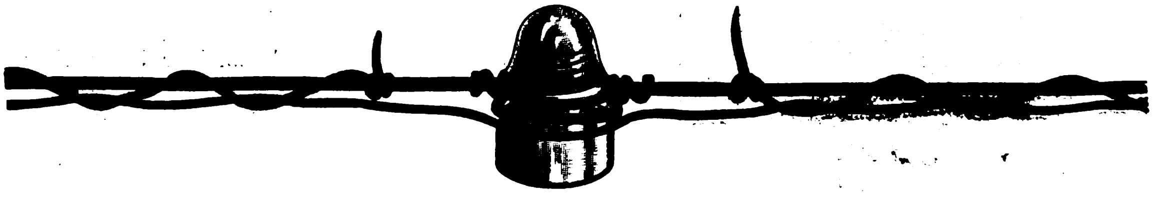
To fully accomplish this result, it is necessary to give a lateral displacement between opposite diameters of the discs equal to the thickness of the rawhide discs. It is also necessary that the number of teeth on the composite pinion should not be exactly divisible into the number of teeth on the all-metal wheel, and it is desirable that the numbers of teeth should be prime to, or incommensurable with one another, so that each tooth on the pinion shall be brought into engagement with each tooth on the gear-wheel.

To prevent the rawhide discs from slipping when clamped between the metal discs, the end faces of the latter are provided with projections, as shown in Fig. 3, which enter the rawhide. These projections are struck up out of the surface of the discs like the teeth of a file, and grip the rawhide securely.

Actual results already obtained with this new form of composite gear, have demonstrated that the difficulty formerly experienced is entirely avoided, so that another step has been effected in the economical operation of electrical railways.

THE SIMPLEX ANTI-INDUCTION WIRE.

Since the introduction of electric light and power circuits, and more especially since electric railways have become so common, the telephone and other delicate electric apparatus, have suffered considerably from induction troubles. Many attempts have been made to remedy this evil, and a variety of so-called anti or non-induction wires and cables have been invented with more or less satisfactory results. Recognizing the want for a thoroughly non-induction wire, the Simplex Electrical Company, of Boston, have recently brought out a wire which is specially designed for use on telephone lines, municipal signal systems, etc., and wherever a "silent" wire is required. To secure these results they have designed an arrangement by which there is secured, (1) a metallic circuit, (2) the parallelism of the conductors, and (3) placing them so that they may be close to each other and yet are kept absolutely apart, so that a short circuit is impossible.



Simplex Anti-Induction Telephone Wire.

These conditions are completely met in the wire shown in the accompanying engraving. The combination consists of a main copper conductor No. 16 B. & S. gauge, and a return wire of No. 10 galvanized iron, both wires being thoroughly insulated with the regular "Simplex" insulation. The two wires are kept close to each other, and yet always separate, by an ingenious weaving of cord formed of insulating material. As shown in the engraving, the line is entirely supported by the iron wire, thus attaining great tensile strength, and relieving the main conductor of all strain, one of the most important features being, that the main conductor is not tied anywhere, not even to the insulators. The separating cord is made of hemp, and is thoroughly saturated with insulating compound.

A telephone line composed of this wire, and about a mile long, has been in use for over a year in Boston, from the office of the Simplex Electrical Company. It runs on the same cross-arms with heavy power lines, and no inductive effects have ever been observed. At present there is a line 1¾ miles long in St. Louis, running from the office of the Municipal Electric Light and Power Company to their station, and they are so well satisfied with it that they propose to extend its use. In Pittsburgh, also, there is a telephone line 10¼ miles long, with twelve stations along the lines of the Federal Street and Pleasant Valley Electric Railway, the line being strung on the same iron posts with the railway feeders, without a particle of induction. The Simplex company put up these lines and guarantee absolute freedom from induction. The wire is made up complete at the factory and shipped in reels, with instructions for erection, which any lineman can understand

DR. DUNCAN'S ELECTRIC MOTOR.

Heretofore the employment of the two-pole dynamo and motor has necessitated a high rate of speed of the armature in order to obtain a proper efficiency with small weight, but it was soon recognized that a similar result could be obtained by the application of the multipolar principle, and indeed the drift at the present time seems to be largely in the direction of the construction of such machines. In carrying out the ideas on this line, Dr. Louis Duncan, of Johns Hopkins University, has designed a construction such that, with relatively small weight, high efficiency may be obtained and by which the revolving parts move at a low rate of speed. The machine is shown in perspective and partly in section in Figs. 1 and 2 and will be seen to consist of an armature, C, which is centered on the shaft, A, and which is under the inductive action of the magnets, B, the form of which is clearly shown in Fig. 4. These consist of a cylindrical portion which is shrunk on the shaft and have polar projections bent so that their inner surfaces form right angles enclosing the armature, and so arranged that the ends of the projections on the one side are midway between the projections on the other side. The engraving shows the armature having 28 polar projections, 14 on each side. The field windings, it will be noticed, are divided into two coils and are so connected as to magnetize the field magnets in the same direction. The essential feature is that the polar projections of one polarity on one side are opposite the spaces between those of opposite polarity on the other side and are fewer by some even number than the coils on the armature, the object of which will be described presently.

In the machine illustrated the field magnets revolve and are attached to the shaft, A, which it drives. The armature C is stationary, being held fast by the lugs shown. The armature is a ring similar in form to the well-known Pacinotti or Gramme ring, but differing essentially as to the method of winding. In a motor having 28 polar projections, as the one illustrated, it has 30 coils *d d′*, surrounding it, the adjacent coils being wound in opposite directions instead of all being in the same direction, as in a Gramme ring. This is shown in Fig. 3, there being a wire taken from the junction of the adjacent coils *d d′* to one bar of a 30-part commutator, as in the ordinary Gramme armature.

The commutator may be stationary, as shown in Fig. 1, or revolve, as shown in Fig. 5 at D′. In the former case the brush holder is revolved by a series of gear-wheels, so that the brushes make fourteen revolutions for every revolution of the magnets.

In the form of commutator shown in Fig. 5 the commutator has 420 segments, forming the commutator-bars, divided into 28 groups of 15 segments each. It will be observed that there are one-half as many segments on the commutator D′ as results from the multiplication of the number of polar projections by the number of coils on the armature. The turning of the commutator D′ coincides with that of the motor-shaft, A.

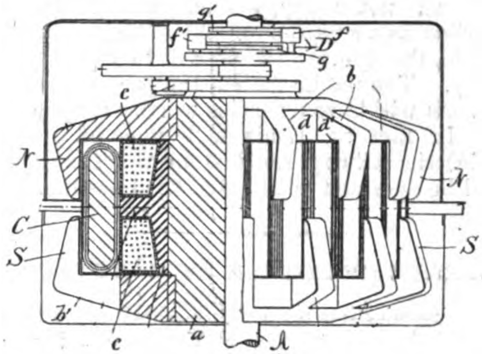


Fig. 1.—Duncan's Multipolar Motor.

The path of the current through the armature is shown by the arrows in Fig. 5. When the brushes are upon the segments shown, all the teeth of the armature are energized excepting those between the coils *d d′*, shown on both sides of the armature. These portions, by reason of the direction of the current and the windings of the coils, are consequent poles, and therefore not energized. The connections of the brushes are so arranged that when the current enters the coil *d d′* the teeth between those coils are exactly opposite the polar projections of the field-magnet.

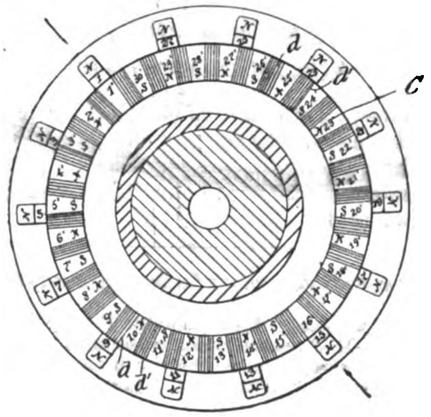

Fig. 2.—Duncan's Multipolar Motor.

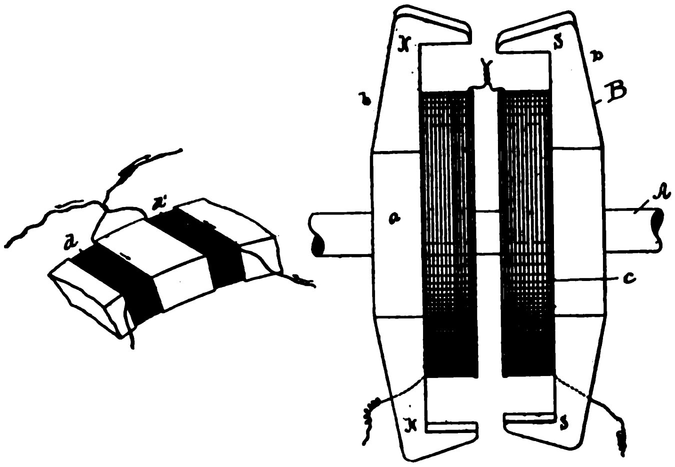

Figs. 3 and 4.—Duncan's Multipolar Motor.

When the commutator has moved through one four-hundred-and-twentieth of a revolution, the teeth between the succeeding coils will be exactly opposite the succeeding polar projections. The same instant the brushes pass upon the succeeding segments of the commutator; these segments are divided into groups of fifteen each, and it is so provided that all the segments of each group send the current in the same direction, and also that each succeeding group of segments shall change the direction of the current. It is evident that there will be twenty-eight changes of the current at each revolution of the commutator—a number corresponding to the number of polar projections in the field magnet.

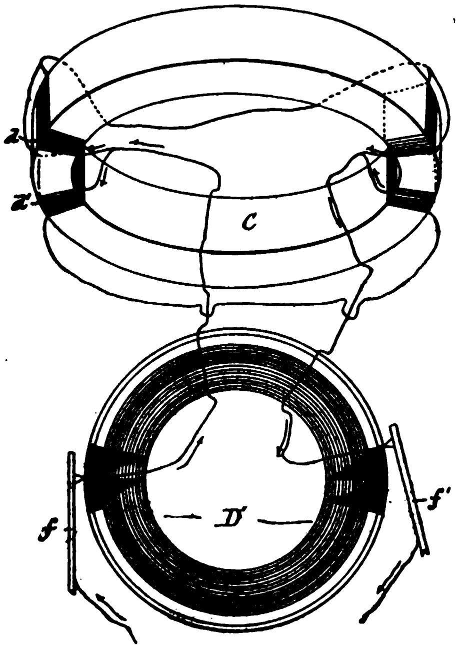

Fig. 5.—Duncan's Multipolar Motor.

The result of this arrangement is a steady continuous pull at the periphery of the armature which permits of obtaining a high effeciency at a comparatively slow speed.

THE MARX ACCUMULATOR.

The principle of an accumulator recently brought out by Herr Marx, of Berlin, is briefly as follows: If an electric current is passed through a dilute solution of hydrochloric acid and perchloride of iron, in which are immersed carbon electrodes, the following reaction takes place: $2\,FeCl_2 + 2\,HCl = Fe_2Cl_6 + H_2$. If, then, a carbon and an iron electrode are plunged into the electrolyte, the following reverse reaction, giving rise to a powerful current, takes place: $Fe_2Cl_6 + H_2O = 1\,FeCl_2 + 2\,HCl + O$. The perchloride may be prepared by taking 450 parts of protochloride of iron, 900 of water, and 500 of hydrochloric acid (25 per cent). The perchloride can then be concentrated, or even crystalized by evaporation, and in that state may be carried about. The carbon electrode in the second case must be very porous, or pierced with numerous holes. The iron electrodes are not consumed; on the contrary, on open circuit iron is deposited on them, so that they must be removed when the battery is not at work.

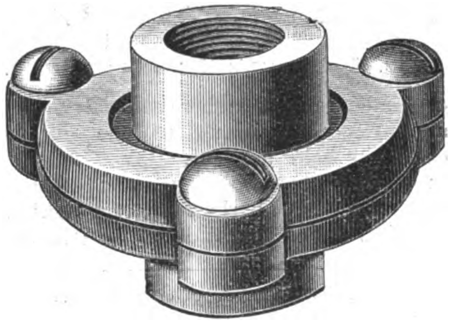
ALLOYS FOR STANDARD RESISTANCES.

At a recent meeting of the Berlin Physical Society, Dr. Feussner, in describing the methods employed at the Government Physico-Technical Institute for the measurement of electrical resistances, remarked that German silver wires had shown themselves unsuited for standard resistances, since their resistance increases regularly with lapse of time. On this account an alloy of copper and nickel was examined which is known commercially as "patent nickel." Wires made of this alloy possess a very low temperature-coefficient, and were found to be almost absolutely constant after being heated to 100° C. Several other alloys were also tried, as, for instance, various combinations of copper and manganese. Dr. Feussner stated that up to 30 per cent. of manganese—above which amount it was not possible to draw a wire in this alloy—they had yielded a negative temperature coefficient. When the alloy contained only a small percentage of manganese, the coefficient wasvery small, so that such wires would be suitable for the construction of standard coils.

GENNERT'S INSULATED JOINT FOR ELECTRIC LIGHT FIXTURES.

The success of incandescent lighting to-day, or, what amounts to the same thing, its rapid introduction into fine buildings and houses, depends greatly on the ingenuity brought to bear upon the details of the work. Anyone who will take the trouble to look through a collection of the devices of the past will be forcibly impressed with the crudeness that was permitted in some of the prime essentials of interior construction ; and he will see at once that the same careful study that brought the art of gas lighting up to its present point of perfection was necessary before the sanguine hopes of the electrical engineer could be even remotely realized.

Lamp sockets, keys, switches, ceiling blocks and cutouts, and many other details have thus been worked at and patiently brought up to the requisite standard of excellence ; and on this page we illustrate an improvement in insulated joints for electric lighting fixtures, especially of the class known as "combination fixtures." While to the uninitiated, the part in question may seem of small account, they who have been "through the mill" know how often and how seriously trouble has arisen just there. This improvement is the recently patented invention of Mr. E. F. Gennert, the superintendant of the E. P. Gleason Mfg. Co., of this city, whose object was to avoid the use of the ordinary unions, insulated screws, and other objectionable features, and to produce a joint of simple mechanical construction, easy of connection, capable of being kept tight, also having great strength, and an insulation which would render less possible the short-circuiting which is liable to occur by reason of the insulating material becoming coated with coal-tar, moisture, or other deposit from coal-gas when the joint is used on a combined gas and electric fixture. Most of our readers are doubtless familiar with the joint hitherto made by the company named, as it is in extensive use throughout the country. This new joint adds in various ways to the merits of the old joint, besides admitting of much cheaper production, so that it is intended to place it in direct competition with inferior joints whose sole virtue has lain in their dangerous and delusive cheapness. As will be noticed, there has been added a nipple of insulating material through which runs the bore or gas way. This nipple is of such a length that it leaves only the threaded ends of the joint uncovered. As these ends are engaged one by the service pipe and the other by the chandelier or fixture, it practically interposes a break of insulating material between the service pipe and the fixture, of such length that no deposit of carbon or other conductive matter from the gas can possibly carry a current across it. The conditions that are created favoring a short circuit by such gas deposits, are familiar to boards of underwriters, and others giving the matter their attention, and a hearty welcome awaits all such devices tending to establish for the incandescent light the truth and stability of its claims to safety and general superiority.



Gennert's Improved Insulating Joint.

AN ELECTRICAL SOLUTION OF THE DIFFICULTY.

Not long since there was trouble in St. Louis over the use of bobtail cars. The passengers would not deposit their fares in the box, but would pay the five cents only to a conductor. As the cars carried no conductors, the drivers had to collect the fares, and as may be imagined their life was not a happy one. Things began to look serious, when as a solution of the difficulty and an end to the trouble, the companies offered to equip their roads electrically. The public hailed the proposal with delight, and St. Louis will have a service worthy its population and wealth. In fact St. Louis will now have one of the largest electric railway services in the country, and the roads will be operated on the overhead system.

CHLORATE OF POTASH BY ELECTROLYSIS.

A manufactory has been established under the name of the Société l'Electro-Chimie, at Villers-sur-Hormes (Oise), for the electrolytic production of chlorate of potash by the patented process of Gall and Montlaur. A second and more important works is to be established in Switzerland, at Vallorbe. The raw material is chloride of potassium in aqueous solution. The electrodes are surrounded by diaphragms, of which the composition is kept secret. The current should measure five volts at the terminals of the bath, and it produces a decomposition of the chloride of potassium according to the formula

$$KCl+3H_2O=KClO_3+6H.$$

In practice several baths are mounted in series, and at the Villers-sur-Hormes works the current is 1,000 amperes at 25 volts. The output is at present 1 kilog. ($2\frac{1}{5}$ lb.) of chloride of potassium per 20 h. p. hour. This would correspond with $\frac{1}{2}$ cwt. of coal.

MAGNETIC SURVEY OF GREAT BRITAIN.

At a recent meeting of the London Physical Society, Prof. A. W. Rücker, F. R. S., communicated some of the results most recently obtained in the Magnetic Survey upon which he has been engaged in conjunction with Prof. Thorpe for some time past.

The Professor observed that in the account of their work already published they had pointed out that the tracts of country surveyed could be divided up into distinct districts ; and the distribution of the magnetic force in these districts had led them to form the provisional hypothesis that the variations were mainly due to the presence of large masses of magnetic rocks. If the hypothesis were correct it was to be expected that the vertical magnetic force would be a maximum over the central portions of such a mass, and that the horizontal forces would be deflected toward the centre. This had only been absolutely proved to be the case in two instances, though in other instances it appeared highly probable.

In order to investigate the matter further they selected two test districts for more minute examination last summer. The districts selected were the west coast of Scotland, and Lincolnshire and Yorkshire. These were selected because, in the first place, the local variations in these districts were very considerable, owing, probably, to the large masses of basalt present in them, and in the second place because they lay near the boundaries of the survey, so that any errors in the calculation of the normal force would be most likely to show themselves there. Magnetic maps of these districts, plotted from the obsrevations made last summer, were then exhibited.

The map of the Lincolnshire and Yorkshire district exhibited a magnetic ridge line, coinciding with the line of the Wealds, and along this ridge line the local variation in the vertical force was a maximum, while the horizontal forces were deflected towards it at points on either side of it. The map of the West Coast of Scotland showed that the distribution of the magnetic force was of the character which would be expected to follow from the presence of a large submerged mass of magnetic rocks off the south-west coast, due south of the Hebrides. The authors had calculated what the forces ought to be according to some observations made by Welsh in 1859 and 1860, and they found that they led to the same conclusions as their own.

In conclusion, Prof. Rücker stated that an application was being made to the Royal Society to assist in carrying out further observations.

THE BRUSH ARC LIGHT PLANT AT THE U. S. NAVY YARD, WASHINGTON, D. C.

BY GILBERT WILKES, ENSIGN U. S. N.

This plant, the pioneer shore electric installation for lighting purposes in the Navy, has just been completed, the contract having been awarded to the Brush Electric Company last fall. Not only has advantage been taken of the most approved practices at the time of commencing work, but several novel features have been introduced with good effect.

In order to avoid the expense of additional boilers, the dynamo house was built adjoining the main boiler house, which supplies steam for the machine shops surrounding it. The power plant comprises two Armington & Sims 10½ by 12 in. engines, each of which drives two Brush 30-light, 2,000 c. p., arc dynamos. The general arrangement of the station is shown in the engravings, Figs. 1, 2, and Fig. 3 shows a plan of the foundations.

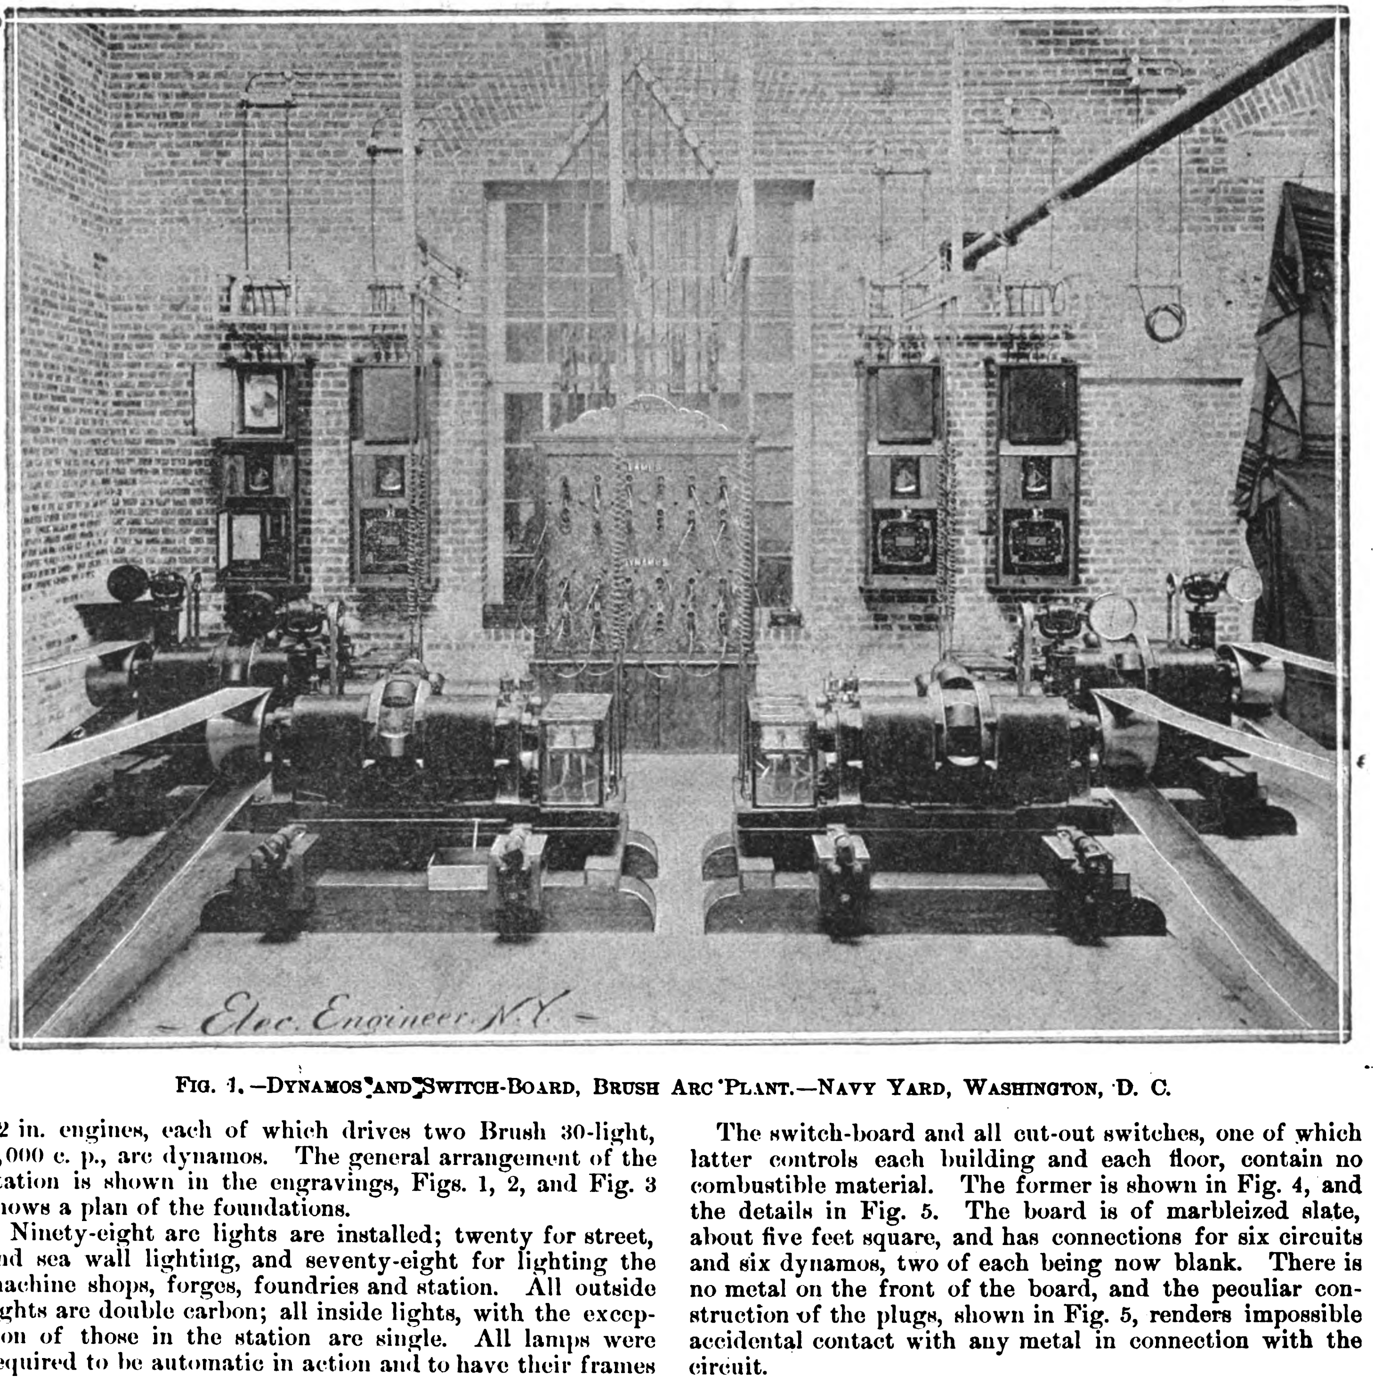


Fig. 1.—Dynamos and Switch-Board, Brush Arc Plant.—Navy Yard, Washington, D. C.

Ninety-eight arc lights are installed; twenty for street, and sea wall lighting, and seventy-eight for lighting the machine shops, forges, foundries and station. All outside lights are double carbon; all inside lights, with the exception of those in the station are single. All lamps were required to be automatic in action and to have their frames and casings insulated from the circuits.

The outside lines are run on dressed chestnut poles at a height of twenty-five feet from the ground. All of the wire used is that manufactured by the Bishop Gutta Percha Co., and was required to show an insulation of 1,000 megohms per nautical mile after an immersion of twenty-four hours. The lamp posts, which are of iron, have two insulating joints of hard rubber. All inside wiring is run on glass insulators, except in the dynamo room where porcelain knobs are used. Even here no concealed work has been allowed, and all wiring is in sight, being overhead.

Throughout all parts of the system every precaution has been taken to effectually guard against danger of shock and liability to fire. The dynamo frames are laid on an inch bed of sulphur, to prevent the absorption of moisture from damp contact with the foundations; the holding-down bolts are capped with wood, and the commutators and brushes are covered with glass cases, only the wooden handles of the rocker clamps extending through slots in the sides of the cases.

The switch-board and all cut-out switches, one of which latter controls each building and each floor, contain no combustible material. The former is shown in Fig. 4, and the details in Fig. 5. The board is of marbleized slate, about five feet square, and has connections for six circuits and six dynamos, two of each being now blank. There is no metal on the front of the board, and the peculiar construction of the plugs, shown in Fig. 5, renders impossible accidental contact with any metal in connection with the circuit.

Two long shops, containing heavy lathes and overhead traveling cranes, at first seemed to present a difficult field for lighting, but an excellent illumination has been obtained by suspending the lamps from iron outriggers, attached below the level of the cages, to the pillars supporting the crane tracks and about 18 feet from the floor. The lower halves of the glass lamp globes for inside use are ground in order to avoid shadows.

The following is a brief summary of the tests made upon the plant by the Government before acceptance.

Engines.—Two Armington & Sims, single, non-condensing engines, 10½x12 in.; 275 evolutions; variation in speed between no load and full load, two per cent.

Dynamos.—Four Brush 30-lighters, 2,000 c. p.

Heating.

Dynamo.	Length of run.	Load.	Heating above atmospheric temperature.	
			Armature coils.	Field coils.
B	7¼ hours.	25 lights.	48° F.	28° F.
C	7¼ "	25 "	56° F.	30° F.
E	6¼ "	29 "	54° F.	44° F.
F	6¼ "	19 "	44° F.	26° F.
E	2 hrs. additional	25 "	56° F.	46° F.
F	2 " "	25 "	46° F.	28° F.

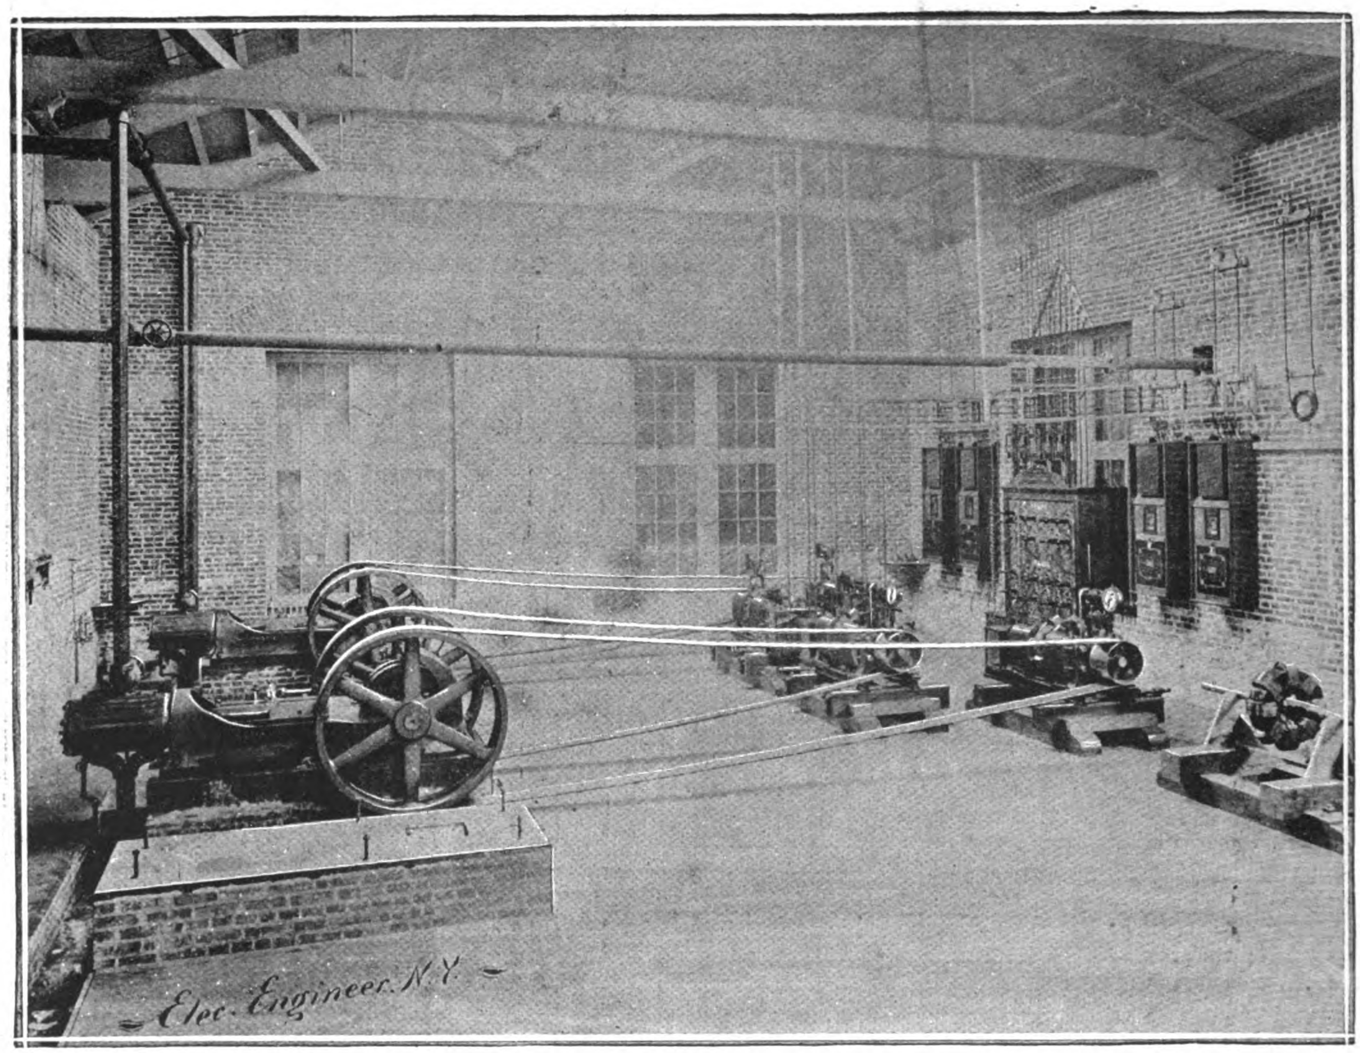

FIG. 2.—DYNAMO AND ENGINE ROOM, BRUSH PLANT.—NAVY YARD, WASHINGTON, D. C.

Efficiency.—Efficiency Test of E and F—driven from engine No. 2.

A Taber steam indicator was supplied by the Bureau of Steam Engineering, Navy Department.

The electrical instruments used were two Thomson astatic voltmeters and two Brush ammeters.

The voltmeters were adjusted previous to the test and the ammeters were standardized. Ammeter E was 2 per cent. high, ammeter F 2½ per cent high. Two readings of each instrument were taken to correspond with each card. The record is given below:

Efficiency Test.

Number of card.	m. e. p. per card.	End.	Constant for 275 rev.	Revolutions.	Amperes.		Volts.	
					E	F	E	F
1	32.5	Front	1.428	278	9.50	9.40	1290	1310
					9.45	9.35	1300	1310
2	32.5	"			9.50	9.35	1310	1320
					9.45	9.30	1310	1330
3	35.5	Back			9.55	9.30	1340	1320
					9.65	9.30	1400	1350
4	35.2	"			9.65	9.30	1410	1340
					9.65	9.30	1420	1340
5	13.2	"		284	Friction of engine only.			
6	13.0	"			"	"	"	"
7	1.93	Front			"	"	"	"
8	1.30	"			"	"	"	"

The speed was taken at each card and was steady.

The above figures give as the commercial efficiency of the Brush 30-light (2,000 c. p.) dynamo a fraction over 84 per cent.

Insulation.—The insulation of the lines was as follows:—

Number of circuit.	Class.	Number of cut outs.	Number of lamps.	Length of wire in feet.	Insulation.
1	Outside.	1	25	10,000	Over 10 megohms.
2	Shops.	1	25	5,000	"
3	"	5	29	5,000	"
4	"	2	19	5,000	"

When the tests were commenced, the insulation of the dynamo circuits from the earth was a few hundred thousand ohms, probably owing to the fact that the machines had been standing unused several weeks in the new damp building. After the runs necessary for testing—about 30 hours—the insulation rose to the following figures for the four dynamos—

B	750,000 ohms.
C	1 megohm.
E	900,000 ohms.
F	600,000 "

It will be seen by reference to the diagram, Fig. 3, that ample space is left in the dynamo room to provide for future enlargement of the plant.

FIGS. 3, 4 AND 5.—PLAN AND DETAILS OF THE BRUSH PLANT.—NAVY YARD, WASHINGTON, D. C.

WORDS OF GREETING.

THE ELECTRICAL ENGINEER appeared for the first time as a weekly journal on April 7th, having hitherto been published monthly for just ninety-nine numbers up to the date of the change. Mr. T. Commerford Martin and Mr. Joseph Wetzler, formerly of the *Electrical World*, are the editors under the new order of things, and we are sure these gentlemen enter upon their new undertaking with the best wishes of all who know them.—*Street Railway Journal, N. Y.*

MR. R. E. CROMPTON ON ALTERNATING AND DIRECT DISTRIBUTION.

WRITING to a friend in this country, Mr. R. E. Crompton says in a recent letter :—

With reference to the remaining part of your letter, I cannot help smiling at your using the expression that I have become a convert to the alternating system. I must say that I have not become so more than I used to be. It is very curious to me to see how completely I have been misunderstood both in this country and in America. I have always said that there is a proper sphere for the high pressure alternating system, using transformers and another sphere of operations for the low pressure continuous system.

The point in dispute has been where to draw the line between the two. I have never denied for a moment that for lighting scattered towns or suburban districts the alternating system is the most suitable, but I have denied that it is so for London or other large towns of the same nature. I notice that you American electrical engineers yourselves are beginning to appreciate the fact of the wide difference between the electric lighting hitherto carried out in America and the electric lighting as carried out in England. In most cases your lighting is for large buildings, such as hotels, large shops and public buildings, or offices and business premises, in fact, where the light is wanted for regular hours and where regular quantities of light are switched on.

In England, on the other hand, the bulk of the lighting is in private houses, each house having a very small number of lights in constant use, but, on account of our habit of entertaining at home, *i. e.*, giving balls and parties, each house is fitted with a large number of lights—in most cases ten-fold the number ordinarily in use. The result is to open tremendous difficulties in the way of the alternating transformer system, as each house must be fitted with enormous transformers, which are excessively uneconomical during the greater part of the year.

Hence, you will see that the present American demand is infinitely more in favor of transformers than it is here. I have also recently learnt the great difference between our lighting in London and yours in most of your great cities. Here the town is carefully districted out. We are compelled to lay conductors throughout the entire length of certain streets and to supply light to any householder who asks for it throughout the streets. Consequently, whether we wish it or not, a certain length and weight of conductor must be laid down sufficient to supply the entire number of houses fronting the streets. The cost of laying these conductors in London is almost independent of the weight of the copper in the conductors, as the cost is so largely made up of the cost of laying and making preparations for connection to houses.

On the other hand, in America, as far as I can understand, your companies as a rule extend their mains wherever they can get permission to do so in order to pick up customers, and as there is no dividing up of the city into districts each to be served by a supply company, in the sense that we have it in England, I fully agree that the alternating system, with its great flexibility, is well suited for so picking up custom in all parts of the town.

These two points, in which electrical supply in England and America differ so widely, are quite sufficient to account for the extraordinary misunderstanding and controversies in regard to the merits of the two systems of supply.

PROFESSOR ELIHU THOMSON ON "THE PROBLEMS OF THE FUTURE."

THE Thomson Scientific Club, of Lynn, Mass., celebrated on May 13th the first anniversary of its formation. Mr. S. E. Randall, who presided, introduced Professor Thomson, himself a past president, who spoke as follows :—

I am on the programme to speak on a subject which rather makes me a prophet; this subject is, "The Problems of the Future," and anything on this point necessarily reduces itself to a matter of opinion. We may predict and be mistaken. There are so many channels in which our sciences may develope that we cannot really say where they may run to. In electrical engineering, above all, we may expect the most stupendous advances. I need not say that this profession is the most modern of all, and a growing profession ; one which has attracted some of the greatest and brightest minds, and will continue to attract them. It has grown up in a very few years. I remember very distinctly, when I was a small boy, that all we knew was related to the telegraph and its working ; otherwise all was confined to some few experiments in the laboratory. We all know how this is now vastly changed ; there is scarcely a department of science which does not involve in it some electrical process, so greatly have the advantages of this branch been recognized. We find the process of evolution carried on and the laying aside and forgetting of other ideas. We can see that the foundation on which we have built is gradually becoming more and more firm, so that the engineering problems can be worked upon to-day, provided we have our facts properly organized. Some five or seven years ago it was more a matter of guess-work to determine the problems which presented themselves in electrical work, and those who could guess the best would show the best results. Faraday, for instance, was able to guess nearer the truth than another man would arrive at by a long course of mathematical working.

The future still looks bright; we need have no fear but that there will be just as much room for work as in the past, and a continually expanding field. We see a number of problems not yet resolved, but some have reached their final resolution. It is not a difficult undertaking to design dynamo-electric machinery of 300 to 500 h. p., which we regarded at one time as gigantic, when machines of 50 or 60 h. p. were considered as very large ones. The day is certainly coming when we shall find dynamo machines up to thousands of horse-power, where power is to be transmitted on a large scale or a great deal of lighting is to be done from a central station. The ideal system is one whose mains will supply all that is needed, whether in the way of light, power or heat, and all from the same mains without having a multiplicity of them.

It is much more easily told what will be the direction with regard to construction and arrangement of machinery than to foretell the discoveries which may be made to change the face of things. We hope the day will come when we shall be able to produce electricity from fuel direct; this is a great engineering problem, just how to do it; but there are not enough facts at hand at present to work upon. There is the thermo battery, consisting, as it does, of nothing more than a series of metals properly connected and heated at their junctions ; still, from this we obtain so little economy that the dynamo is very much ahead of it, though the present generating plant is cumbrous.

There are some obscure effects when heat is thus applied to metals, causing slight currents to travel through the circuit, but these effects are too small to be of any practical use ; the ideal arrangement being, as it were, a furnace which consumes the fuel and passes the energy along conductors to be used as required. If this came about, steam engineering would receive its death-blow. We can imagine a locomotive which obtains its current by combustion at places along the track, or even on the engine itself. This would enable us to do a great number of things which we now find expensive—it would light our buildings cheaper and decrease the cost of traveling. There is hope for such things, but I do not know if it will come in our days ; it is hardly possible for its growth to be too rapid, but a great deal of scientific work will have to be done first.

In the near future railways will be run by electricity ; not the small local roads, I mean, but the large ones connecting cities, and there is no reason why we should not expect higher speeds than we can attain at present with our steam locomotives. There we have reciprocating parts, parts which must be put into motion, stopped and reversed continually, while in the electric locomotive we have the simple rotary motion, which is all we need, and which makes it possible accordingly to run at a much higher rate of speed. Although the steam locomotive has been much improved, yet it can hardly compare with the economy of stationary engines placed where they can have an abundant water supply for condensation. We can, therefore, by employing stationary engines and electric roads do away with a great deal of unnecessary weight, and, the moving parts being symmetrical, we can attain a much higher speed—say 100 miles an hour. This would be a grand step forward which would save us a great deal of time. It might even be possible, making necessary arrangements to keep the train to the track, to reach a speed of 150 miles an hour. I really think that if we could come back after another hundred years, this would be the speed of traveling. It simply depends upon finding the necessary arrangement for applying sufficient power and the building of locomotives.

There is another field—the electro-chemical field. We know that electricity has been largely applied to the extracting of metals from the ores and their refining. As every chemical operation is nothing more or less than a changing about of affinities or likings for each other among the particles composing bodies, and, as electricity can govern these operations, it is evident that chemical operations can be conducted by electricity. There is room for investigation on this point, but it is a rare thing to find a man who is an accomplished chemist and at the same time a practical and thorough electrician. I might even go so far as to say that since all operations, such as the growth of plants, are known to be based upon chemical reactions, and many of them can be reproduced in the laboratory, so in the far future our food may be reproduced by electricity. We can make grape sugar, for instance, and it may be that we could, in a certain sense, become independent of farming. We may cause the combination of elements to take place which does take place in the growth of plants, so that we could take water-power and manufacture food.

These are only ideas thrown out which may be extended greatly, the getting of light without heat, for instance. That is undoubtedly one of the most engrossing engineering problems and one of the most desirable things we could wish to come about.

Our incandescent lamp produces a great deal of light, but there is some considerable heat too; we want to do without these low heat rays, and then we should obtain light at an exceedingly small cost.

These problems may be resolved in our time, but we have the satisfaction of knowing there is plenty of work to do in the future. (Cheers.)

TELEPHONE ENGINEERING.[1]

BY JOHN J. CARTY.

ELECTRICAL engineering is a young man's science. When Dr. Harvey announced his discovery of the circulation of the blood, there was not a physician over 40, who believed in the truth of his doctrine. The older men of the present day do not altogether reject electrical innovations and are in some cases even too credulous, yet the discoveries in science crowd upon each other so rapidly that only the minds of the younger men are sufficiently plastic to accept the changes which are constantly being made. While there is no science which stands in greater need of the calm and deliberate judgment which comes only with mature years, the extreme newness of electrical engineering places the young man and the old upon the same basis as regards experience, yet gives the former a tremendous advantage on account of the energy and enthusiasm of youth.

No disgruntled old fogy can tell us how he used to build telephone exchanges before we were born, nor that he operated a double trolley road in the "wet Fall of '38." On the other hand we cannot have the advice or experience of our elders in the technical troubles which daily beset us. A stranger going into the office of an electrical engineer with whom he is not personally acquainted is quite likely to make a mistake and select one of the clerks as the engineer.

Electrical engineering, although so new, has already divided itself into specialties and sub-specialties. None of its various branches offers a broader field or a more fascinating future than telephony. There has been a disposition to reserve the term "engineering" for the so-called heavy branches. There is nothing to support such a position, as although the telephonist is not called upon to deal with such works as a Brooklyn Bridge, or a St. Gotthard Tunnel, yet telephony is not so favored by gravity that its follower is not obliged to engage in some works which are heavy, and which require a high grade of mechanical skill.

A telephone office with 6,000 subscribers requires at least 20,000 wires; the 200 cables required to extend them from the switchboard to the basement of the building weigh 250 tons, and the task of so arranging them that any cable may be drawn out at will and be replaced by a new one is by no means simple; and where space is of such value as it is in this city, the question is further complicated by economical considerations affecting the room at our disposal.

The difficulties of underground construction can only be appreciated by actual contact with the subject; not only must the subways be kept ventilated and cool, as heat is an enemy of all insulation, but grave chemical and mechanical questions are encountered at every turn. The question of telephone cables alone is worthy of a life study by the most ambitious student.

A large switchboard, such as exists at Cortlandt street, New York, weighs 55 tons, and contains 1,980 miles of wire, all of which is laid out according to an elaborate and intricate system not equaled outside of the human body.

The analogy between the nervous system and the modern telephone exchange is striking and instructive, alike to physiologists and electricians. The general similarity between the telegraph cable and a bundle of nerves is well known and described in all works on anatomy. But there are certain special likenesses of structure which suggest similarity of action and which have never received the attention of physiologists on account of their not being familiar with telephony. For instance, in some of the highly specialized telephone systems, there are two wires extending to each subscriber; one by which messages are sent from the subscriber to the central and the other over which the central office sends communication to the subscriber. In the nervous system there is a perfect counterpart to this in the sensory and motor nerves. In case the finger is touched to a red hot iron, a message of pain is sent over the sensory nerve to the brain, which may be considered the central office of the body. Upon the receipt of this impulse at the brain a signal is transmitted along the motor nerve to the finger which is immediately withdrawn from the iron by the proper muscle. In the case of a learner at the piano, the movements of the fingers must be directed in detail from the brain, but after much practice this work is performed automatically by a ganglion, or knot of nerves, which may be considered as a branch office of the brain.

A parallel to this is found in a telephone system when subscribers at a distance from the exchange require constant communication with each other. The business is at first handled in the main office, but after its nature is discovered, a separate small office is established near the subscriber and the main office is relieved of this work.

If the line leading to a subscriber's station is cut off at a half-way point and a signal is sent to the central office, the operator there will naturally suppose that the call comes from the subscriber's station, although connection therewith has been entirely severed. Something like this happens when a man's arm has been cut off and the surgeon makes a bad job of it. The irritation of the ends of the nerves at the stump which formerly led to the fingers is supposed by the central office at the brain to come from the fingers and a sensation of pain at the fingers is produced, which is just as real as though they were attached to the body, instead of being buried in the family lot.

A section of one of the conductors sometimes used in the switchboard presents a remarkable resemblance to a section of a human nerve when viewed under the microscope, and the appliances used in telephone wires to prevent induction present an appearance strongly suggesting certain incisions and indentations in the envelopes of the nerves, the use of which has never been quite clear.

There is no doubt that impulses are transmitted along the nerves and it is no more than reasonable to suppose that, as in the case of telephone conductors, there should be devices employed to prevent lateral action between the nerves, both by conduction and induction. If such appliances do exist it would be of the greatest interest to the telephonist and to the physician to establish the fact, and from some investigations which I have seen conducted I think it may some time be done. I do not mean to imply that there is any identity between electricity and nervous force, or to give any aid or comfort to those charlatans who say that "electricity is life," or to the crank who talks of animal magnetism and has a headache unless he sleeps with his head to the north. I simply point out an analogy which may be helpful.

The electric light engineer can get along with the most superficial knowledge of the telephone, but the telephone engineer is obliged to follow closely the work of his colleague, the so-called "heavy engineer." The interferences produced in the telephone by railway and electric light circuit due to contact and proximity are of such a serious nature that in self-defense, if for no other reason, the telephone man is forced into the subject. The question of regulating electric light wires so as not to interfere with telephone lines requires a joint knowledge of both sides of the subject, and in endeavoring to protect his telephone line from contact with naked trolley wires, the telephone engineer is led quite as deeply into the question of fuses and other protecting devices as a man can well go. Aside from this, in many respects telephone practice is an exact counterpart of modern alternating current electric lighting, for in each transmitter is a converter presenting problems of design not inferior to those met with in electric light converters. Telephone repeating coils are simply converters which are expected to work at a high efficiency under variations of load, sometimes amounting to 1,000 per cent.; that is, they must be so constructed as to be operated by the most delicate voice currents and also respond to the comparatively heavy signaling currents from the alternate current generators which are employed. A modern telephone line containing 20 stations operated in multiple arc affords as beautiful an an example of the utilization of counter E. M. F. as can be found.

The telephone itself is an alternating current generator, whose output is so small that there are elements in line construction, to insure successful working, which have to be considered by the telephone engineer, but are ignored and in many cases almost forgotten by his electric lighting confrere.

Electro-static capacity is one of the most serious elements to be contended with in telephone construction. Were it not for this factor telephoning around the world could be accomplished with ease. The exact nature of this action in its bearing on telephony is not generally understood. The near proximity of telephone conductors brings out this effect very strongly, and although it can be somewhat reduced by a judicious selection of the dielectric, or medium separating the conductors, yet with our present knowledge there is no hope of getting a medium which shall permit less induction to take place through it, than air.

The problem then becomes a mechanical one and consists in keeping the conductors as far apart as possible. Of course, in underground cables this cannot be carried out to any extent, owing to the limited space at our command; but with aerial lines the case is different, and were it not for the limitations upon overhead construction imposed by the various municipal authorities a long distance telephone system between the most distant cities of the United States could soon be an accomplished fact. With overhead lines the question of space is not the only important one, but a high grade of mechanical and electrical engineering is required to construct a pole line. In a modern long-distance line the poles are set at exact distances apart and the tops kept as near the level as possible, and all strains are carefully distributed. It is due to these methods that during the great blizzard the long-distance wires furnished the only means of communication with the outside world although one message was sent from this city to Boston via London, by Atlantic cable.

After the pole line is erected the task of so arranging the wires that they shall not affect each other or be interfered with by any extraneous circuits is one for which we cannot turn to the text books for aid. The true theory of transpositions has never been published and I do not know half a dozen men who could design a transposition system for a twenty wire line from New York to Buffalo. The researches of Hertz, Lodge, and others have an important bearing on the inductive action between the telephone conductors, and as I have previously pointed out, they suggest a possible way out of the difficulties by some arrangement of dielectrics to control this action. The work of these experimenters should be closely followed by telephonists throughout the world.

---

[1] A paper read before the New York Electrical Society, May 15, 1890.

Telephony is not wholly confined to the study of electricity; a broad and comprehensive knowledge of the subject requires also some familiarity with the physiology of the human voice and ear, and an intimate acquaintance with the science of acoustics. A telephonist should be a good deal of a physicist.

The phonograph is destined to form an important part of the telephone system of the future. At some time no doubt a phonograph may be inserted in a telephone line to act as a sort of "talk meter," recording all conversation which goes over it. I once thought of a curious use to which the phonograph might be put; that is, in transmitting speech through one of the existing ocean cables. I have no doubt that a cable could be designed which would enable us to talk direct to Europe. In such a cable the idea would be, to have the capacity and resistance as low as possible. Perhaps if there were a cable ten feet thick we might talk through it. With the present cables signals are transmitted so slowly that before one telephone vibration reaches its destination another is piled in on top of it and confusion is the result. Now, my idea was to first speak into a phonograph and then turn the cylinder at a speed no faster than the cable can take care of the impulses, and to have at the other end a phonograph also revolving slowly, (but not necessarily synchronously), upon which a record would be made. This second cylinder could then be revolved at the proper speed and if all went well the transmission of speech through an existing ocean cable would have been accomplished. It has been estimated from a microscopic examination of the word "Hello" on a phonograph cylinder that it contains sixteen thousand indentations. If this is true, it would be quicker to send the phonograph cylinder by mail than to rely upon the cable.

The radiophone of Prof. Bell involves the most delicate and complicated theories of interaction within human knowledge; by means of this wonderful instrument, as you all know, it is possible to telephone between distant points without the aid of a wire. The ether is used to convey the impulses. This instrument has not yet found its way into practical use, but must some day form an important part in telephone systems.

Telephone engineering is a science of the future. It is interesting on account of its possibilities rather than because of what has been accomplished. At the same time, the work which is daily being carried on by the system of the Long Distance Company shows that the plant of that company is unique among the engineering feats of the world.

Before the introduction of the telegraphs and railroads into this country it was doubtful if our union of states would be rendered sufficiently homogeneous to hold together; but steam and the telegraph have up to the present time enabled us to expand far beyond the conceptions of our fore-fathers and still remain the prosperous and united country that formed their ideal. Still, as our civilization becomes more complex, there is a demand for a more complete intimacy between the various portions of our body-politic, and the long distance telephone comes in to meet this want and supplement the railroad, telegraph and mail.

There is a possibility in connection with long distance telephone service which has never before been pointed out, and that is, its effect upon the language of our nation. As is well known, where people in different sections of a country rarely come in speaking contact with each other, there is a gradual change in the language which ultimately results in the formation of a dialect, and while the telephone can never compensate for those differences in speech which are due to climatic influences, it will be an important factor in preserving the uniformity of our language.

The telephone has never been used in a great war, but it is capable of martial application, perhaps not as important, but not less unique, than characterizes its use in time of peace. A short time ago, General Manager Hall, of the Buffalo Telephone Company, assembled in less than half an hour the entire Board of Trade of that city to attend a meeting on an important subject connected with their commercial interests, and which meeting could only have been called by the aid of the telephone. This should suggest to our military authorities its utility in the mobilization of the various state militia organizations. With a telephone in every block in every city in the land, it would be possible to assemble all of the state militia of this country in a few hours. In Germany, the telephone, like the telegraph and railroad, is controlled by the government, and telephone officials are assigned to a regular place in the field, to be taken on the commencement of hostilities.

Some time ago, Mr. Preece made some experiments to determine the effect of the great Deptford 10,000 volt alternating current dynamo upon neighboring telephones, and he came to the conclusion that when this dynamo was working all of the telephones in London would be interfered with, owing to their connection with the earth. At that time I pointed out that by means of a dynamo properly connected with the earth and a set of telephones a besieged garrison might communicate with a relief party by signaling through the earth itself. Similar signals might be sent with the aid of a telephone from a ship to the shore, or from one ship to another. In this connection a remarkable statement has recently been attributed to Mr. Preece to the effect that the operation of the Deptford dynamo created disturbance in the telephones of Paris.

It has not been my purpose in this paper to foster any antagonism between the different schools of electrical engineers, but rather to counteract a growing tendency on the part of young men in choosing a profession to consider the telephone question as solved, and not presenting a field in which their energies and abilities could find proper scope.

RESEARCHES ON THE ELECTRIC PROPERTIES OF RAREFIED AIR.[1]

QUITE recently Dr. Hertz has succeeded in obtaining an experimental realization of one of the ideas held in common by Prof. Poynting and Mr. Heaviside concerning electric oscillations, *vide* Wiedemann's *Annalen der Physik und Chemie*, T. xxxvii., page 395. It is believed that the electric oscillations in a wire take their origin at its surface; that they are extremely rapid, and that, while remaining practically superficial in character, they penetrate more or less into the interior. Dr. Hertz devised a sort of cylindrical cap which should serve to figure the conducting wire; 24 very fine wires were arranged between two metallic discs, the centres of which were connected by means of a sort of metallic axis which could have its metallic continuity interrupted by a spark micrometer placed on the axis. With this arrangement Dr. Hertz has succeeded in demonstrating that an electric oscillation does confine itself practically to the surface of a conductor, for it does not produce sparks in the micrometer that is placed on the axis which traverses the centre of this conductor.

These experimental results have induced M. J. Moser to direct his attention to the action of electric oscillation in rarefied air. In his investigations, the results of which were communicated to the Paris Academy of Science on February 24th,[2] 1890, he used rarefied spaces, without any metal or electrode of any kind, as conductors for the oscillations.

It has often been observed that tubes of rarefied air become luminous when they are in the immediate neighborhood of an induction coil that is being worked, but such tubes, according to all accounts, have been of the Geissler type, and have consequently been furnished with metallic electrodes which traversed the glass, or with electrodes which were simply applied to the exterior surface of the glass, like those of Gassiot. Moser's experiments, however, were carried out with tubes which were not then provided with metallic electrodes. The presence of the electrodes has hitherto always complicated the attempt to explain the phenomena which occur, and Moser believes that the elimination of these disturbing factors will tend to simplify the solution of many difficult problems in physics.

The arrangement devised and adopted by Moser was as follows:—A glass tube of air, 40 cm. long and 3 mm. in diameter, had its contents rarefied by means of a Geissler pump, after having been sealed off before the blow-pipe; this tube was then enclosed in another glass tube of 10 mm. diameter, and rather more than 40 cm. in length. The exterior tube was sealed up at one end, and at the other it was hermetically connected with a Geissler air pump. The rarefaction of the inner tube remains, of course, invariable, whilst that of the outer tube can be varied at pleasure.

When such an arrangement is brought into the neighborhood of an induction coil in action the inner tube becomes brilliantly luminous, showing a clear blue coloration without any lines of stratification if the outer tube has not yet been exhausted. When, however, the outer tube is exhausted, and its rarefaction varied, whilst that of the inner tube remains always constant, some remarkable phenomena are noticed, accompanied by unexpected variations in the color of the luminosity.

These seem to show, according to Moser, that three states of rarefaction are to be distinguished, these states of rarefaction being characterised by different electrical proportions. Thus air which conducts the induced charge when it is at a pressure of 1 mm. becomes insulating when the rarefaction is carried to the extreme limit—in fact there are three states of rarefaction which may be described as

I. Ordinary vacumm (insulating).
II. Vacuum 1 mm. pressure (conducting).
III. Extreme vacuum (insulating).

---

[1] London *Electrical Review*.

[2] See THE ELECTRICAL ENGINEER, April 9.

It is a well-known fact that Geissler tubes, which are furnished with metallic electrodes, after having been subjected to extreme rarefaction, refuse to conduct the passage of the electric discharge, and this phenomenon has been the subject of much discussion. Some physicists have explained it by supposing the vacuum to possess insulating properties; whilst others, again, have attributed it to a property of the surface of the electrodes, assuming that they offer, under circumstances, great resistance to the passage of the discharge. In Moser's experiments there are no electrodes, so this latter theory breaks down, and the phenomena cannot be due to the resistance and passage at the surface of the electrode. It is indirectly connected in some way with the properties of the vacuum.

Since the results of these experiments were communicated M. Moser has been directing his attention to the study of the specific inductive power of spaces of rarefied air, and he gave an account of his more recent investigations to the Academy of Science at Paris about a fortnight ago.

The specific inductive power was measured in relation to the then states of rarefaction, which have been already alluded to. In studying the problem Moser made use of the following apparatus: —A large Leyden jar was constructed with a double bottom and double sides in such a way that it was possible to rarefy the air in the annular space between the double sides. The internal surfaces of the glass, which limited the air in the annnular space, was covered with layers of silver foil; these layers served as armatures; they were insulated, the one from the other, and communicated with the exterior by means of electrodes. The layer of air between these armatures formed, as it were, the dielectric.

A Geissler pump was connected with the Leyden jar in order to produce the necessary degrees of rarefaction, and these by means of a well-known device could be easily measured. The pump was also connected up with the system of concentric tubes which are described in the first part of the paper, and which was used to demonstrate the variation in the conducting power of varying degrees of rarefaction. An ordinary Geissler tube was also connected up, by exciting which it was possible to estimate the extent of the rarefaction when the manometer showed no appreciable alteration of level.

Moser then determined the conductivity and also the specific inductive power of this system of rarefied spaces, all disturbing influences being carefully allowed for or eliminated. The measurements were then made by well known methods, the only difficulty being the precaution necessary to be taken in order to avoid error. In these measurements a quadrant electrometer was used of the kind known as the Mascart-Carpentier, and with the induction coil and the constant battery a Sabine key was employed.

The jar was always charged for exactly the same time—namely, one minute—so that the results were strictly comparable.

For these states of rarefaction the following deviations were observed:—

I. 10 mm. of Hg.	II. 1 mm. of Hg.	III. Extreme vacuum.
318	318	318
318	320	320
318	320	320

These results conclusively demonstrate that there is practically no variation of the specific inductive power when the rarefaction is varied.

Spaces of rarefied air therefore exhibit two remarkable electric properties—namely, the variation of their conductivity, and at the same time the constancy of their inductive power.

WORDS OF GREETING.

THE somewhat irregular ranks of strictly electrical journalism have been very substantially reinforced by the appearance of THE ELECTRICAL ENGINEER as a weekly instead of a monthly, as heretofore, under the joint editorship of Messrs. T. C. Martin and Joseph Wetzler. These gentlemen have long been known to the electrical profession through their connection with the *Electrical World*, and it is not too much to say that they, by dint of perseverance and the high standard that they have set themselves in all their work, have made that journal what it is to-day, or rather what it was a few weeks ago. THE ELECTRICAL ENGINEER has always been the most scientific of the electrical journals, in fact it is just the paper that electricians take pleasure and profit in reading and preserving. The change from a monthly to a weekly has been welcomed and applauded by all its old readers and by many new ones, doubtless all the more so because that change has inaugurated the reign of Messrs. Martin and Wetzler in the editorial sanctum.—*India Rubber World.*

HIS CHECK NOT HANDED IN.

At the works of the Morgan Engineering Company, at Alliance, Ohio, we recently saw, says the *Iron Age*, an extremely simple arrangement which prevents all liability of accident by electric linemen repairing the conductors or lamps. On the wall facing the dynamo in the engine-room was a board about 6 inches high and 1 foot wide, provided with six hooks intended to receive six numbered checks. There were six men whose duty it was to look after any faults in the circuit and to make the necessary repairs. When any one of these men was called on duty he removed his check from his hook, carrying it with him. A glance at the board showed the engineer that one hook was absent, and that there was, therefore, one man engaged about the lines somewhere in the shop, and his instructions were imperative not to start the dynamo until the checks were in place on the hooks. When in place the engineer then understood that all those who were deputed to look after the lines and lamps were otherwise engaged, and that if any accident happened beyond that through tampering with the wires or through injudicious attempts to make repairs while the current was on he would be held blameless. The extreme simplicity of this method of preventing liability of accidents by the electric current will recommend itself.

ELECTRIC RAILROADING AT BIRMINGHAM, ALA.

NOTHING is more indicative of the rapid growth and development of the South than the manner in which the towns and cities in that part of the Union are adopting electricity for illuminating purposes as well as for operating all kinds of machinery. The street car service is also undergoing a revolution or transformation in that section at a rapid rate, and the time is not far distant when the southern mules—with all their mulish tricks and vices—will be relegated to other service than that of hauling street cars through the handsome cities and prosperous towns now springing up in every southern state.

Among the most prominent cities, which nature appears to have specially designed, by reason of its fine geographical position and almost illimitable mineral resources, to speedily become the metropolis of the Sunny South, is Birmingham, Ala., the citizens of which are as full of "sand" as the citizens of the great English town of Birmingham, the metropolis of the Midlands, after which it is named. The rate at which this southern city is growing is simply phenomenal; and within the last few days there has been commenced there an undertaking surpassing anything of the kind ever before attempted, placing Birmingham in the front rank of American cities. This is the consolidation of the Birmingham and Bessemer Railway Company, the Ensley Railway Company, the East Lake Railway Company, and the Union Railway Company, under the title of the Birmingham Railway and Electric Company. This corporation will now operate from sixty to one hundred miles of road. the entire length of which will be equipped with electricity, This equipment will necessitate an outlay of well nigh $2,000,000 and the contract for the entire undertaking has been placed with the Thomson-Houston Electric Company.

The consummation of this colossal undertaking is due to the enterprise and business capacity of Mr. T. T. Hillman, one of the most brainy, popular and successful men in the South, who, in this great undertaking has associated with him some of the strongest men of Birmingham. This gentleman owns rich coal and iron interests and may be considered one of the commercial leaders. Mr. Hillman has been elected president of the newly consolidated company and Mr. Robert Jeninson, manager. The company will at once place contracts for rails, car bodies, engines and boilers for the central power station which is to be equipped with a steam plant of 2500 h. p. capacity. The overhead construction will be adopted, the centre iron pole being used for supporting the conductors.

This consolidation and the placing of the contract with the Thomson-Houston Electric Company has created quite a breeze in many parts of the South, and it is a positive fact that already its effect is being felt among speculators and prospective settlers, the markets strengthening in every direction. The undertaking is considered by representative men to be fraught with good for the entire South.

THE TELEPHONE IN ENGLISH POLITICS.

THE *Freeman's Journal* of Dublin chuckles over a trick that was played upon the Conservatives on May 14, while a division was impending in the House of Commons on Mr. Russell's motion to adjourn the debate on the Irish agricultural laboror's bill. It appears that when the Conservative whips went to the telephones to summon a long list of members from the clubs for a hurried division, they found the instruments in possession of Parnellite members, who held conversations over the wires with fictitious friends, until the division bell rung, when, of course, it was too late for the wips to secure the aid of the missing members. The result was that the government was beaten of a "snatch' vote.

HON. A. G. BLAIR, attorney general of New Brunswick, president of the telephone company, together with the Hon. W. Pagsley, solicitor general, who is attorney for the St. John, N. B. Street Railway Company, has been in New York on a brief visit, inspecting electrical things, including the Electrical Exhibition at the Lenox Lyceum.

THE ELECTRICAL EXHIBITS AT THE PARIS EXPOSITION.[1]

BY CARL HERING.

PRIMARY BATTERIES.

GENERAL.

AMONG the very many exhibits in this class were a number of improvements and modifications which were of interest and showed some, though not very great, progress. The field being already so thoroughly studied, leaves little room for any very great progress; that shown was mainly in the form of slight, though not unimportant, improvements in the elements of the cells and in the details of construction.

The exhibits of powerful batteries showed that electric lighting from primary batteries is not only possible but also practicable, but even at its best it must still be considered a luxury on account of the expense, though if all of the facts and figures given by one of the exhibitors are correct, it has been reduced to the very low cost of $\frac{1}{10}$ cent per candle per hour, for labor and for material consumed; or $\frac{2}{10}$ cent per candle-hour, including everything. Although this is still between three and four times the cost of gas, yet it makes electric lighting by such means practicable for domestic purposes and for small power.

The very thorough researches of Renard are of some interest, resulting in his obtaining what is undoubtedly the lightest battery yet made. Most of the improvements in batteries were in the details of construction, the only one differing essentially from the old well-known types is the Lalande and Chaperon. In the Leclanché type the tendency appears to be to diminish their resistance, to cheapen the construction and to diminish the attendance required by them; in the latter direction the so-called dry cells are among the chief improvements. The Daniell cell was conspicuous by the absence of any improvements. With the exception of Callaud's well known improvement of employing gravity to separate the solutions, it appears to have originated as an almost perfect cell.

Processes of purifying zinc for the utilization of the residues of batteries, are also being developed. One of the interesting novelties was a battery in which the electricity is a by-product, the object sought for being the residue, namely, sulphate of copper.

Conspicuous by their absence were the inventors so often met, who claim to obtain more energy out of their batteries than is possible under theoretically perfect conditions. This alone is a proof of progress.

Exhibits by Countries.—The exhibits of primary batteries were almost exclusively in the French section, the only exception of note being one English exhibitor.

Classification.—Owing to the diversity of applications of the different cells, no classification will be attempted here, other than that those usually intended for great power will be described first, and those for small currents, last. Such a classification is, necessarily, only a very general one. Those of the first group are almost exclusively improvements and modifications of the bichromate of potash type of cell, and the latter of the Leclanché type.

BICHROMATE OF POTASH CELLS AND THEIR MODIFICATIONS.

The **GENDRON** cell, (French section, Bronze medal) is a zinc-carbon couple, with porous cup. The construction presents some points of interest, the object being to obtain great surface of electrodes, small distance between the plates, small quantities of liquid renewed continually and automatically and kept in continual circulation. The battery is intended to be used for lighting and for small powers.

Details.—The jar is a low, rectangular box made of sheet-iron, covered on the inside and outside with hard rubber which renders it perfectly acid-proof, while the box is light and strong. The porous jar is a narrow vessel with parallel sides, bent around parallel to itself, somewhat like a broad short letter S, the long parts of which (7 in number), are straight and parallel, forming practically several narrow porous cells communicating with one another so as to act as one, there being narrow parallel spaces between each two for a carbon plate. The porous cup has a hole at the bottom over a corresponding one in the jar, with a cock of special construction to drain off the liquid.

Each of the seven zinc plates is made of a number of rectangular pieces of thin sheet zinc, well amalgamated and afterwards secured together so as to form one thick plate amalgamated practically throughout its whole mass. The object of this is to secure good amalgamation and to be able to use the cheap impure zinc of commerce. These zinc plates are held in their porous cups at and by their edges by a three-sided, grooved frame, the open side being at the top. The zincs are thereby held like a slate in its frame and may readily be replaced. This frame is made of copper, well amalgamated, and the contact between it and the plate is made by means of the mercury. This simple mode of supporting the zinc plates has many evident advantages; besides being readily replacable, they are completely immersed and consumed, and the contact is always good and clean. The liquid is dilute sulphuric acid.

The carbon plates are placed between the parallel portions of the porous cup as well as on the inside of the four sides of the jar, being mitered, to hold them in place. The liquid is bichromate of soda.

Drain Pipe.—There is a drain pipe connected with each cell, the object of which is to draw off automatically the old liquid, at precisely the same rate at which the new liquid is being added, so as to keep the cell from overflowing or being drained. The liquid which has become passive is heavier than the fresh, active liquid and sinks to the bottom; the drain pipe must therefore lead it off at the bottom, while at the same time it must not allow the level of the liquid to change. To fulfill this condition it is made of two vertical concentric tubes having an annular space between them; the inside one is open at the top at the normal height of the liquid and leads out through the bottom of the cell and the outside one is open at the bottom and is higher than the normal level. The overflow therefore takes place from the bottom of the cell. There is one of these drains inside the porous cells and one outside. The supply of fresh liquid takes place in one corner of the cell and the drain is in the diagonally opposite corner, thus requiring the liquid to circulate continually through the winding parallel canals between the plates and the porous cup.

The liquids are supplied by lead tubes from two tanks above the battery. These tanks are filled by means of a very simple and ingenious, though not new, acid pump, consisting of a strong, flexible rubber tube laid in the form of a semi-circle and supported by a suitable guide; a wheel of slightly less diameter has rollers on its circumference, each of which in rolling over this tube compresses it and thereby pushes the liquid forward, similarly to the mechanical action of the intestines of the human body.

Size and Capacity.—A cell 18 inches square and 6 inches high, the active surface of the 7 zinc plates being about 5½ sq. feet, gives about 2 volts on open circuit and 100 amperes on short circuit, showing an apparent internal resistance (including polarization) of .02 ohm. The normal rate of discharge is 30 to 40 amperes.

Another exhibit of a complete primary battery for lighting purposes was that of the **AUTOMATIC ELECTRICAL CORPORATION**, limited, (English section, Bronze medal).

Details.—A comparatively small and compact primary battery is automatically and continually charging accumulators, from which the lights are supplied when required. The elements are amalgamated zinc in dilute sulphuric acid in a porous cup and carbon in a solution of bichromate of soda. The fresh liquids are supplied by canals, and the spent liquids are led off through holes in the bottom of the cells, closed by valves of special construction. The draining and refilling are operated electrically every 12 hours for the acid solution, and every three hours for the bichromate solution. A clock starts this operation. The jars are of hard rubber; the reservoirs are of sheet iron, lined with lead.

Output and Cost.—The battery exhibited is said to light 10 to 12 lamps of 10-candle power 6 hours per day, allowing 25 per cent. loss in the accumulators, and to cost $100. The zincs last about a week. The cost of running per 1,000 watts, (by which watt-hours are probably meant), taken from a report of a reliable authority, is about 50 cts., divided as follows: Bichromate, 20 cts.; sulphuric acid, 4 cts.; zinc, 12 cts.; mercury, 1.2 cts.; labor, 11.5 cts. At the rate of 2 watts per candle this corresponds to 500 candle-hours, or .1 ct. per candle per hour, which for a 10-candle lamp makes .1 ct. per hour. A company in London undertakes to install and run the battery, supplying everything, including the wiring for 10 lamps, charging at the rate of 1 penny (2 cts.) per hour per 10-candle lamp, which is certainly very cheap for incandescent lights from primary batteries. They use as a sort of meter the quantity of liquid used. In their factory they utilize the residues.

Another battery of some importance owing to the great power developed from small light cells, is that of Commander **RENARD**, (French section), and called the chlorochromic cell, or the tubular battery, on account of its appearance. It is at present used for small portable table lamps, the battery being in the base of the lamp, and it was suggested to be used to propel the great military balloon "La France." It is no doubt the lightest battery ever made.

General Description.—The cell may be said to belong to the bichromate class, in which the bichromate of potash is replaced by free chromic acid, and the sulphuric acid partially, or entirely, by hydrochloric acid. The cell consists of a long, narrow, cylindrical retaining cell of glass or ebonite; the negative electrode is a concentric tube usually made of a very thin sheet of platinized silver; it may also be of carbon; the positive electrode is a long, thin rod of zinc, concentric with this silver tube and insulated therefrom. The general arrangement of a battery with 12 cells, is shown in the accompanying illustration, Fig. 1.

Solution.—A very thorough scientific and practical research seems to have been made to find the best proportions for the battery solution, and to study its behavior. Of these results, we give here only the most important conclusions. They are doubtless quite reliable. By replacing the usual sulphuric acid, part for part, by hydrochloric acid it was found that the *rate of discharge* for the same cell was increased in proportion as the hydrochloric replaced the sulphuric, being increased five-fold when all the sulphuric acid was replaced, as compared with the usual bichromate solution, with sulphuric acid alone. The *capacity* of all these new liquids, however, remains about the same; that is, as the rate of discharge increases, the time of the discharge diminishes. The more hydrochloric acid there is, the more tendency there will be to disengage free chlorine gas; the liquid should, therefore, not have too much hydrochloric acid and should not be prepared too long in advance. The mixture most frequently used for lighting, in which the proportion of sulphuric to hydrochloric acid (see below) is 80 to 20, is quite stable and can be mixed two or three months in advance. When no sulphuric acid is used, the instability of the liquid is so great that it ought not to be used longer than two days after mixing.

---

[1] Advance sheets of the report of the expert of the U. S. Commission to the Paris Exposition, Section "Electricity."

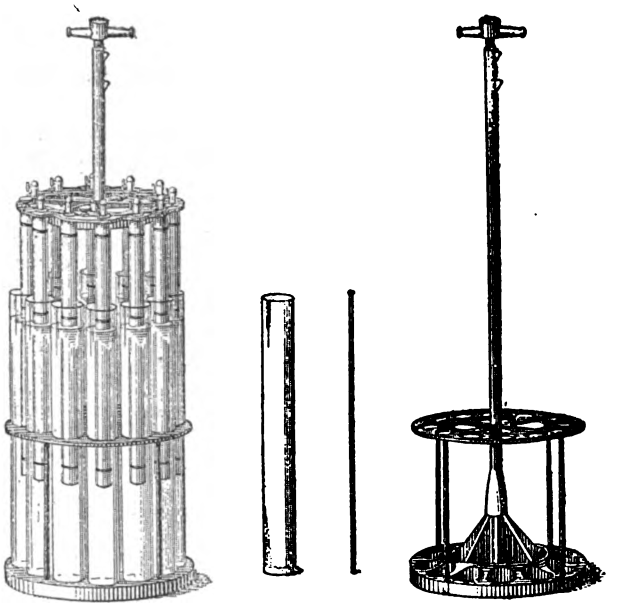

FIG. 1.—THE RENARD BATTERY.

The following three liquids composing the mixture, may be prepared in advance and kept in stock :—

Liquid A : Chromic acid, 530 grains ; water, 770 cub. cms.

Liquid BCl : Commercial hydrochloric acid of 18° Beaumé (or a sp. gr. of 1,143).

Liquid BS : Dilute sulphuric acid of 26° B. (or a sp. gr. of 1.25), consisting of 450 grammes acid of 66° B., and 800 cub. cms. of water.

The greater the proportion of the liquid BCl used, the more rapid will be the rate of discharge, and the shorter the time of discharge. The capacity is the same for all, being 50 to 60 watt hours per litre, the discharge being stopped when the difference of potential has fallen to 1.25 volt per cell. The following figures are deduced from a table given :—

Proportions by volume of the liquids A, BCl, and BS, respectively, 100, 20 and 80 ; specific gravity, 1.27 ; maximum current, 3.5 amperes ; coulombs, stopping the discharge when the current has fallen to half its maximum value, 10,630 ; watt hours, 3.54 and therefore the mean volts must have been 1.20, and the ampere hours, 2.95 ; watt hours per litre of liquid, 54.6 ; watt hours per kilogram of liquid, 43.0 ; weight of liquid per horse-power hour (metric), 17.2 kilograms, or 38.2 pounds. For the proportions 100, 100 and 0 (*i. e.*, without sulphuric acid), the figures are very nearly the same except that the maximum current is 8.5 amperes, the mean voltage remaining exactly the same.

The improvement, therefore, exists in two things, namely, in replacing the potash or soda salt by chromic acid and sulphuric by hydrochloric acid. One or the other of these changes alone will not have much effect, but it is with the two combined that the discharging rate is increased five-fold, and the total capacity increased 50 per cent.

Construction, negative electrode.—The negative electrode (positive pole), is made of a sheet of silver, covered with platinum ; it is 0.1 mm. or 0.004 inch thick, the platinum coating being only about 0.0025 mm., or 0.0001 inch thick. The platinum is necessary for protection, as the silver is attacked slowly when the platinum does not cover it. It is bent into the form of a long, narrow cylinder, the lap of which is left slightly open so as to allow the liquid on the outside to circulate and get into the interior to the zinc. The diameter of this tube should be about .4 to .6 of that of the retaining cell. The cost of such an electrode 1 inch in diameter and 9 inches long is $1.00. Three little hard rubber rings in the inside stiffen it and insulate it from the zinc rod which is passed through the holes in these rings. It may be replaced by a carbon cylinder, but is preferred as its conductivity is better and the weight and volume are less, the latter being practically nothing. It is very expensive, however, and should be replaced by carbon if the maximum output is not essential and the liquids not too concentrated.

Positive Electrode.—The zinc used is in the form of a thin zinc wire. It is made small in order to diminish the local action, (which is proportional to the surface) and so that it may be consumed completely by one charge of the liquid. The smaller the surface of the zinc, the more nearly is the consumption proportional to the current. Tests show that 1 litre of the liquid dissolves 85 grams of zinc. This would, however, require a zinc wire too small to be practicable, especially as the action is more rapid at the top than at the bottom, and would result in cutting it off at the top. It is therefore made slightly larger, in general .16 of the diameter of the cell, which is about ¼ inch for the normal cell. It is not amalgamated, and for several reasons. It was found that after a certain point of concentration was reached the amalgamated and unamalgamated zincs are attacked equally by local action. Furthermore, it increases the expense and makes such a thin rod as brittle as glass. Unamalgamated zinc also enables a leaden retaining tank to be used for table lamps, which would be destroyed by a single drop of mercury from the zincs.

Characteristics.—The characteristic of a cell is the curve obtained from the values of the difference of potential and the current corresponding to successive values of the external resistance varying from infinity or open circuit, to zero or short circuit. For a theoretically perfect cell, that is, without polarization as, for instance, in a Daniell cell, this ought to be a straight line, as in the accompanying diagram, Fig. 2, (excepting the curved part K A.) in which 1.67 would be the voltage on open circuit and 35.7 the amperes of current on closed circuit. The *constants* of such a cell would be the E. M. F. 1.67, and the internal resistance, which is evidently the quotient of 1.67 volts and 35.7 amperes, that is, 0.047 ohm. The curve shown is one actually obtained from one of these cells, without sulphuric acid. The points K and L are those between which the cell is used in practice, for which, therefore, the constants are those above given. For other cells, however, this characteristic is always a curve. By drawing a straight line through that portion of such a curve which represents the normal working conditions, and prolonging this line, the constants may be shown in the same way.

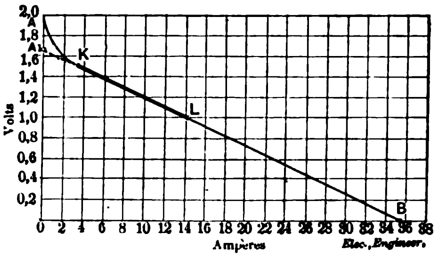

FIG. 2.

Output and Capacity.—The following are some of the dimensions and capacities of these cells. Diameter of cell, 1⅝ inches; tube of silver, about ¾ an inch; that of the zinc, about ¼ inch; height, not given, but probably 9 to 10 inches; difference of potential while working normally, 1.20 to 1.25 volt; internal resistance, 0.17 ohm; discharge stopped when the voltage had fallen to about 1.12. The solution was the one described above, 100, 20, and 80. 24 cells connected in series were discharged continuously through 3 lamps of 27 volts and 1.25 to 1.3 amperes each; the total quantity of liquid used was 6.3 litres. It ran 140 minutes, having given 347 watt-hours, making 55 watt-hours per litre of liquid, or 18 litres per kilowatt-hour. Constructed as light as practicable, it will weigh 40 kilogr. per kilowatt-hour, everything included, or almost 66 lbs. per useful horse-power per hour. For practical batteries of this class, it is doubtful whether this weight can ever be diminished materially.

The following are the dimensions and figures regarding the battery which is intended to propel the great military balloon "La France:" Cells, 4 cms. diameter; silver tube, 3.2 mm.; zinc, 6.4 mm. Total weight of a battery of 12 cells connected 6 in multiple arc, 10 kilogr. The useful power at the end of one half hour's running was 220 watts, thus requiring about 4 of these batteries per kilowatt ; or with a motor, about 4 batteries, weighing 40 kilogr. for a useful horse-power hour measured at the shaft. The weight that could be carried was 400 kilogr., therefore making 10-horse-power, or 7.5 kilowatts for 1 hour and 36 minutes. While these results are very good and far superior to others obtained, the inventor himself admits that we cannot hope that electrically driven balloons will ever be successful implements of war.

Table Lamps.—The following data is given by the maker of the table incandescent lamp furnished with a battery of these cells in its base. Weight, complete, 35 lbs.; height, clear, 33 in.; lamp, 25 candles; volts, 10 to 11; amperes, 4; mean duration, 5 hours,—maximum, 8 hours; price, $60; cost of recharge, 50 cts.; cost per candle-hour, 56 cts. The liquid is raised or lowered by air pressure produced by a small rubber bulb.

References.—For a more thorough description see the first volume of the *Bibliothèque de la Revue de l'Aeronautique*, a very complete abstract of which is published in *L'Electricien* of Paris, Nos. 363–4, March 29, 1890, *et seq.*, from which the above illustrations were taken.

EXPERIMENTS WITH A PENDULUM-ELECTROMETER, ILLUSTRATING MEASUREMENTS OF STATIC ELECTRICITY IN ABSOLUTE UNITS.[1]

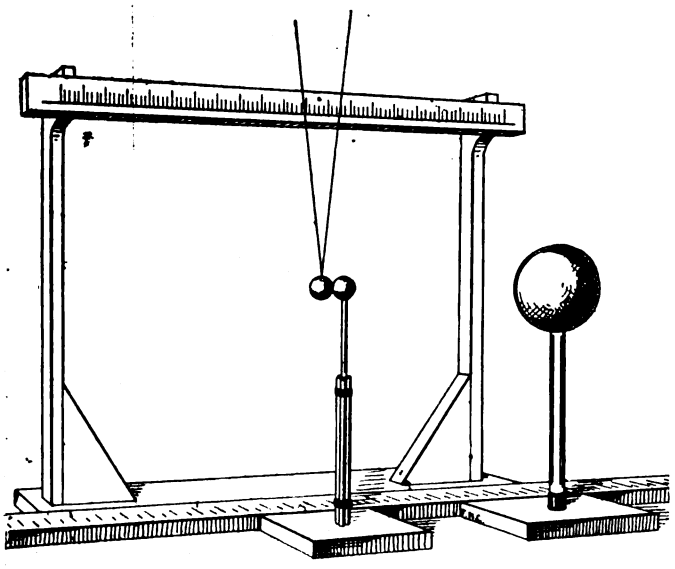
BY PROF. ALFRED M. MAYER.

Description of Apparatus.—A sphere, accurately turned out of velvet cork to 1 cm. radius, with a smooth surface, was heavily gilt. A staple made of fine wire was driven into this sphere, and a very fine filament prepared from a cocoon of the silk-worm was passed through the staple and the ends of the filament were attached, at a distance of 52 cms. apart, to a support near the ceiling. In this bifilar suspension the effect of torsion is eliminated, for the twist of one length of the thread is opposed to that of the other. The vertical length of the pendulum is 364 cms. or nearly 12 feet.

A scale of millimeters, pasted on a slip of glass is placed behind the suspending threads and 34 cms. above the center of the suspended sphere. A black band (not shown in figure) is painted along the lower edge of this scale, so that, when the line of sight is in the plane of the two threads of bifilar suspension, we see a fine white line on this black ground. This permits fine readings of deflections along the scale of millimeters.

The force pushing the pendulum from the vertical will be as the weight of the sphere and ½ the weight of suspending thread into the sine of the angle of deflection. The weight of sphere and one half of thread is 990 mgrms., and the force of *one dyne* will give to the pendulum a deflection from the vertical of 3.4 mm. on the scale above the sphere, if we take g=980.2 cms. at Hoboken.

As not over 2° of deflection was used in the experiments, it follows that the difference between the sine of the deflection and its chord is just measurable, amounting to only ⅙ mm. fo an angle of deflection of 2°. The scale was inclined to the horizontal so as to coincide with the chord of 2°.



PENDULUM ELECTROMETER APPARATUS.

Another sphere of brass of one cm. radius was supported on a rod of glass; the latter coated, while hot, with a film of paraffine. This rod was mounted vertically on a wooden base which slid along a scale of millimeters on a table. This scale and the one before which the pendulum is deflected are so placed that when the suspended cork-sphere and the sphere on the rod are just in contact the threads of suspended sphere read 0 on the upper scale, while the vertical plane through the center of the sliding sphere reads 2 cm. on the lower scale, this being the distance apart of the centers of the spheres.

The ends of the thread, to which the gilded cork-ball is suspended, are passed through small staples in a board fastened to, or near, the ceiling, and are then joined together and passed around a spool fixed by a screw midway between the staples. By turning the spool the thread is wound on or off it, and thus the height of the pendulum is adjusted so that its center and that of the sphere on the glass rod are in the same horizontal line. When this adjustment has been made the head of the screw is tightened on the spool.

The sphere on the rod is charged and then slid along the scale on the table till it is in contact with the sphere of the pendulum. The charge is thus equally distributed between the spheres; and when the sphere on the rod has been brought to 2 cm. reading on its scale, the deflection on the upper scale plus 2 cm. gives the distance of centres of spheres apart, and the force (f) in dynes in the rate of 3·4 mm. to the dyne and $f=\frac{qq'}{D^2}$; and since $qq'=q^2$, $q=D\sqrt{f}$, as the sphere, being of 1 cm. radius, has unit capacity.

Influence of the surface of the room and of surrounding objects on the capacity of the sphere.

If we assume (to be within bounds) that the above influences are equivalent to a sphere of 100 cms. radius, concentric with the suspended sphere, we have $C=\frac{rr'}{r'-r}=\frac{100}{99}=1.01$. This gives for the effect of the induction of the room in increasing the capacity of the sphere, the same as would be produced by increasing the radius of the sphere by $\frac{1}{10}$ mm.; a quantity too small to be taken into account in experiments with this apparatus, as it is not possible to form the sphere to this degree of precision. We would here remark that this apparatus is not an instrument of extreme precision, though it will measure to $\frac{1}{30}$ of a dyne, and with a sphere of pith, which has ⅙ of the specific gravity of cork, it may measure to the $\frac{1}{60}$ of a dyne, if the apparatus is guarded from air currents; but this instrument gives the means of readily making electrostatic measurements before a class, and of presenting clear conceptions of the nature of these measurements.

Experiments to determine if apparatus gives the law, $f=\frac{qq'}{D^2}$.

Eight experiments are given in the following table. The first column gives the number of experiment; the second, the deflections in centimeters of the pendulum; the third, the corresponding distances of the centres of the two spheres; the fourth, the direct ratios of the deflections; the fifth, the inverse ratios of the squares of the distances between centres of spheres; the sixth, the approximations to the law of the inverse squares. By approximation we mean $\frac{d}{d'}\div\left(\frac{d}{d'}-\frac{D'^2}{D^2}\right)$.

Exp. 1	d=5·25 d'=1·15	D= 5·25 D'=11·15	$\frac{d}{d'}$=4·56	$\frac{D'^2}{D^2}$=4·51	Approx. $\frac{1}{91}$
" 2	d=5·0 d'=2·4	D= 5·0 D'= 7·2	" 2·08	" 2·07	" $\frac{1}{208}$
" 3	d=4·8 d'=2·3	D= 4·8 D'= 7·0	" 2·08	' 2·12	" $\frac{1}{52}$
" 4	d=3·5 d'=2·1	D= 5·5 D'= 7·1	" 1·66	1·66	" $\frac{1}{\infty}$
" 5	d=2·65 d'=0·87	D= 5·65 D'= 9·87	" 3·046	" 3·051	" $\frac{1}{609}$
" 6	d=2·75 d'=1·5	D= 4·77 D'= 6·5	" 1·83	" 1·85	" $\frac{1}{91}$
" 7	d=3·02 d'=2·87	D= 4·86 D'= 5.02	" 1·052	" 1.066	" $\frac{1}{76}$
" 8	d=3·10 d'=2·94	D= 4·94 D'= 5.10	" 1·054	" 1.065	" $\frac{1}{96}$

The average approximation is quite close to the law, being $\frac{1}{108}$.

One cause of this departure from the law of the inverse squares is the mutual influence of the spheres causing a departure from uniform electrical density over their surfaces.[2] If we replace the cork ball by one of pith, the approximation to the law is much closer, as the distances of the spheres in the experiments are much greater. A gilded pith ball of 1 cm. radius, made of pieces of pith cemented together, weighs, with one-half of the suspending filaments, only ·25 grm., about ¼ of the weight of the cork ball[3] and filament; so that, on the pith ball pendulum, a dyne will produce a deflection of 13·3 mms. This pendulum is not suited to class experiments, as it is too readily moved by air currents, and has to be inclosed in a large cage formed of silk fastened to a light wooden frame. When this pith sphere is thus protected and suspended by an exceedingly fine fibre, it gives as close an approximation to the law of inverse squares as does the Coulomb torsion-balance. Another cause of error is the continual loss of electricity during the experiments. This error can be partly corrected by repeating as nearly as possible the first experiment and properly combining this third experiment with the first. This was not done in those given, our object having been to see how close an approximation to the law is reached by methods suited to experiments before a class. The error caused by loss of electricity can be allowed for in measurements of quantity and potential by a determination of this loss by experiments similar to those given below.

---

[1] *The American Journal of Science.*

[2] On this subject see Sir W. Thomson's Papers on Electr. and Mag., p. 86; and Mascart and Joubert's Electr. and Mag., vol. i, p. 153, and vol. ii, p. 173.

[3] The specific gravity of elder pith, in air, is .04. This I determined by weighing a right parallelopiped cut out of this substance. The specific gravity of cork is .24.

Experiments to determine the law of the loss of electricity, per minute, from a sphere of the radius of (1 cm.) *the unit of capacity.*

The pendulum sphere was touched by the charged sphere on the rod, and the latter remained in one position during the experiments. The deflections of the pendulum and the distances of the centres of the spheres were read every three minutes.

At the heads of the columns following table d stands for the deflections in cms.; D, for the distances apart of the centers of spheres in cms.; f, for force in dynes; q, for units of quantity of electricity.

Times.	d	D	$f = \frac{d}{.34}$	$\sqrt{f}$	$q = D\sqrt{f}$
0m.	3.10	5.10	9.1176	3.02	15.4020
3	3.02	5.02	8.8823	2.98	15.9596
6	2.94	4.94	8.6470	2.94	14.5236
9	2.865	4.865	8.4264	2.90	14.1085
12	2.797	4.797	8.2264	2.87	13.7674
15	2.73	4.73	8.0294	2.83	13.3859
18	2.67	4.67	7.8529	2.80	13.0760
21	2.60	4.60	7.6443	2.76	12.6960

Times.	q	Dif. 0 and 3; 3 and 6, etc.	Mean q	Loss per 3 m.	Loss per m.
0m.	15.4020				
		.4424	15.1808	$\frac{1}{34}$	$\frac{1}{103}$
3	14.9596				
		.4360	14.7416	$\frac{1}{34}$	$\frac{1}{103}$
6	14.5230				
		.4151	14.3160	$\frac{1}{34}$	$\frac{1}{103}$
9	14.1085				
		.3411	13.9370	$\frac{1}{41}$	$\frac{1}{123}$
12	13.7674				
		.3815	13.5766	$\frac{1}{35}$	$\frac{1}{105}$
15	13.3859				
		.3099	13.2309	$\frac{1}{42}$	$\frac{1}{126}$
18	13.0760				
		.3800	12.8860	$\frac{1}{34}$	$\frac{1}{103}$
21	12.6960				

The mean loss per minute is $\frac{1}{103}$ of the charge; and the difference between the maximum and minimum measured is $\frac{1}{565}$. In Coulomb's experiments (Mem. 3d 1785) this difference amounts to $\frac{1}{339}$.

The loss of electricity, as is well known, follows Newton's law of cooling; and these experiments show the operation of this law very closely.

The coefficient thus found is, however, only applicable to experiments made in similar hygrometric and barometric conditions of the air, for the coefficient varies with these conditions.

In the above experiments the barometer was at 30.069 ins.; the force of vapor .251 ins.; and the relative humidity 31.8. Temperature of air, 73° F.

Experiments on the distribution of electricity on a cylinder, like the one experimented on by Coulomb.

In his sixth paper, of 1788,[4] Coulomb gives his measurements on the distribution of electricity on a cylinder with hemispheric ends. In was 30 French inches long and 2 French inches in diameter. I made a similar cylinder of wood neatly covered with thick tin-foil. With it I made the following experiments to test the value of the pendulum-electrometer from measurements that could be compared directly with those made by Coulomb with his torsion-balance.

To do this I had first to determine the fraction of the charge lost by this cylinder per minute. This I did by transferring, at intervals of three minutes, a proof-plane from the charged cylinder to the stationary sphere of the pendulum-electrometer, and made a series of experiments similar to those given under "Experiments to determine the law of the loss of electricity, etc." It was found that the charged cylinder lost .04 of its charge in one minute.

The following experiment, No. 9 of the series given, will show the manner of procedure in making a measure of electric density at a point on the cylinder.

Proof-plane carried from contact with middle of cylinder to stationary sphere of pendulum-electrometer gave a deflection of the pendulum of 3.55 cms., with distance of centers of spheres of 5.56 cms. $\sqrt{3.55} \times 5.56 = 10.43 =$ charge on middle of cylinder. After an interval of two minutes the following measure was obtained from charge of proof-plane conveyed to electrical-pendulum from contact with the end of the cylinder:

Deflection of pendulum = 6.7 cms.

Distance of centers of spheres = 8.7 cms.

$$\sqrt{6.7} \times 8.7 = 22.53,\ 22.53 + (22.53 \times .08) = 24.33,$$

$$\text{and } \frac{10.43}{24.33} = 1 : 2.33.$$

That is, the ratio between the electric density on the middle of the cylinder to that on the end is as 1 to 2.33.

The following measures were made in the above manner:

	Density on Middle.	Density on End.		Density on Middle.	Density on End.
1	1.00	2.42	7	1.00	2.21
2	"	2.36	8	"	2.31
3	"	2.20	9	"	2.33
4	"	2.22	10	"	2.23
5	"	2.26	11	"	2.26
6	"	2.20	12	"	2.21
	Mean = 1		:		2.27

Coulomb gives for the distribution on this cylinder the following ratios:

At middle of cylinder.......... .... 1.00
" 2 ins. from end.................. 1.25
" 1 in. " " 1.8
" end............................ 2.3

The mean of our measurements gives for the ratio of densities at middle and at end of cylinder, 1 : 2.27, which is substantially the same as Coulomb's ratio of 1 : 2.3.

Measurements of Quantity and Potential.

The quantity and potential of the charge on a sphere of known radius are readily measured by the pendulum-electrometer, as shown by the following experiments:

The charged sphere, of 1 cm. radius, was brought in contact with the electric pendulum, and the force in dynes exerted on the latter was 7.058. The distance apart of centres of spheres was 7.4 cms. This gives for the quantity (Q) on the pendulum, $Q = \sqrt{7.058} \times 7.4 = 19.7$ units of electricity.

As soon as the readings of the deflection of the pendulum and the distance apart of centres of spheres were obtained, the sphere on the rod, of 1 cm. radius, was removed and a charged sphere of 4.6 cm. radius was brought opposite the charged pendulum. The deflection of the latter was now 3.5 cms.; the distance of centres of spheres 28.5 cms., and the force of deflection in dynes 10.29. The quantity, Q′, on larger sphere is

$$Q' = \frac{fD^2}{Q} = \frac{10.28 \times 812.25}{19.7} = 424.26$$

units of quantity.

As the potential (V) of the larger sphere is equal to the quantity (Q′) of its charge divided by its capacity (C), or radius in centimeters, we have

$$V = \frac{Q'}{C} = \frac{424}{4.6} = 92.2 \text{ units of potential.}$$

The foregoing experiments show that the pendulum-electrometer gives the law of inverse squares, serves to determine the law of dissipation of electric charge, and with it one may make measures of the electrical distribution on conductors and determine quantity and potential. In short, this simple apparatus affords an inexpensive and ready means of presenting clearly to students the nature of measurements of static electricity; and allows one to make these measures in absolute units before a class with ease and dispatch.

Stevens Institute of Technology, Hoboken, N. J.

NEW HAVEN, CONN.—THE New Haven Electric Company are making arrangements for a complete new station, which will be situated on the shore at Fairhaven. It will be constructed on the Thomson-Houston system throughout, and compound condensing engines will be used, with Babcock & Wilcox boilers. The new station will supply all the arc light circuits in New Haven, and about 2000 incandescent lamps, while the old station will be given up entirely to the incandescent business, which is rapidly increasing.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Board of Electrical Control—A Simple Explanation of the Keely Motor—Close of the Edison Electrical Exhibition—Electric Roads for Brooklyn.

THE Board of Electrical Control has had some more meetings, but without much result. At the session on May 16th, the United States, the Brush, and other electric light companies withdrew their applications for ducts they had previously made, for the purpose of revision. The revised applications will be presented to the Board this week. There is a dispute between the Board and the Police and Fire Departments with regard to the occupancy of ducts without charge. The two departments do not want to be "ducted" together. Each wants a duct of its own.

The Board has had its existence lengthened for one year, by a bill passed by the last Legislature, at the request of Commissioner Hess. It is believed that the governor will sign the bill.

The New York *World* has had an interview with Keely, the mysterious motor man. The inventor very frankly told the reporter the whole modus operandi of his wonderful discovery. Here is the pith of the whole matter as divulged by Mr. Keely himself: "There is a triple sympathetic order of vibration diverting the positive and negative currents to one general polarized centre; this rotary action is continuous when sympathetically associated with the polar stream."

The Edison Electrical Exhibition in aid of the Women's Exchange was brought to a very successful close last week. It is understood that several thousand dollars will be netted. A bit of interesting news is that the exhibit will be transferred bodily to the Great Northwestern Exposition at Minneapolis, where the old effects will be reproduced on a larger scale and many new ones added.

The application of the Brooklyn City Railroad Company for permission to substitute electric motors for the horses now used on its cars means a great deal more than appears on the surface, and is probably the first step towards the adoption of that system of locomotion by every surface road in town. The City company is the largest horse-car concern in this country. It controls over 600 miles of tracks and has a transfer system which connects all parts of the city. When electricity is finally introduced this transfer system is to be still further enlarged, and the time occupied in traveling about town will be very materially reduced. President Lewis, who has been urging the substitution of electricity for horses for a long time, is very enthusiastic over the prospect of getting it on his roads. "It is the coming power," he said the other day, "and we propose to utilize it. In all probability we shall have two power stations, so that we shall not be inconvenienced if one blows up. I am very strongly in favor of supplying power from one central station to all the roads that will use electric motors. That would reduce the cost to a minimum." In view of the interest in the subject, the Brooklyn Institute invited Mr. T. C. Martin to lecture before the Institute last week, and accordingly, Saturday evening was devoted to "The Electric Railway in its Social and Scientific Aspects," when a large audience gathered. Mr. James Hamblet presided. The lecturer based his address chiefly on the paper recently read by him before the New York Electrical Society. A large number of views were exhibited by lantern, showing the arrangement of the motors, the methods of line construction, etc. A number of new views never before shown were also exhibited of roads and cars of the Sprague, Thomson-Houston, Daft, Julien, Rae, Short and other systems.

NEW YORK, May 19, 1890.

BOSTON.

Grand Jury Acquit Sizer—Lecture by F. S. Pearson—Electric Legislation—Elevated Railroad Bills all Tabled—West End Increase—Meeting of the American Institute of Electrical Engineers in Boston—Complimentary Dinner to the Members by the Boston Electric Club.

IN the report of the Grand Jury no bill was found against D. W. Sizer, the driver of the West End Car, which hit the horse on which the late Mr. G. H. Bradford was riding, when the latter was thrown and killed. The Grand Jury has had the matter of indicting Sizer under consideration for the past two months.

Mr. F. S. Pearson, electrician of the West End Street Railway, gave an interesting talk this week before the Parker Memorial Science Class, his subject being Electricity and Electric Cars. Mr. Pearson's explained by diagrams the construction of electric generators and motors, and explained the single and double trolley system. He claimed that the 500 volt current generally used for railway purposes was entirely harmless and could not possibly kill anyone.

The committee on manufactures reported "ought to pass," with amendments, on the bill to permit the consolidation of gas and electric light companies. One amendment is that the agreement for consolidation shall be executed by the presidents of the constitutent companies only after it has been approved by vote of two-thirds in number and interest of the stockholders of each corporation, at a special meeting. Instead of "majority of the appraisers" fixing the capital of the new corporation, the "appraisers" may do it.

The committee on mercantile affairs has been given some very interesting hearings on legislation growing out of the conflict between the two electric light companies at Middleboro. The trouble there is alleged to have resulted from the course of the gas commissioners in encouraging both companies to go ahead. The bill which the committee has under consideration provides that in any city or town in which a company is engaged or organized for the purpose of the manufacture and sale of electric light and power, and in which, with such company, the city or town has made a contract to light its streets, and has given its consent to such company to lay, erect or maintain wires over or under the streets, lanes and highways, and such company has laid, erected and maintained such wires, the consent heretofore given for the purposes aforesaid is thereby confirmed; and such company is authorized to lay, erect and maintain such wires; provided, however, that this act shall not exempt such company from any duty required by the general laws in relation to the manufacture and sale of electric light and power. In Middleboro, the local authorities support the local gas company, which also furnishes electric light, while the commissioners licensed another company finally. For this reason a general law is desired.

A bill has been reported to authorize the Nantucket Electric Street Railway Company to do business as a common carrier.

The elevated railroad bills all received attention this week, and at one time it looked extremely probable that the West End bill would go through, all the other bills having been tabled. The street railway committee actually did report a bill allowing the West End company to construct and equip an elevated railroad. The latest report, however, from the State House, states that the bill has been tabled along with the others, and it is not likely to come up again for some time.

The selectmen of Brookline gave a public hearing on the petition of the West End Street Railway Company for leave to construct, maintain and use a double track on Chestnut Hill ave., beginning at the dividing line between Boston and Brookline on and running southerly on Chestnut Hill ave., with curves into a proposed car house about to be erected by the company; also for leave to operate the company's cars on the proposed tracks by the overhead single trolley electric system of motive power, and to make the underground and surface alterations of the street, and to erect, maintain and use poles, wires and electrical appliances necessary for that purpose.

The American Institute of Electrical Engineers will hold its general meeting at the new building of the Massachusetts Institute of Technology, Boston, on Wednesday, May 21st, at 10 o'clock, when some very important papers will be read on various electrical topics, by some of the brightest men in the electrical profession. On Wednesday evening, the members of the Institute will be the guests of the Boston Electric Club at a dinner, to be served at the Parker House, at 6.30 o'clock. A paper will be read under the auspices of the Club, by S. E. Barton, of Boston; on "The Relation between Fire Insurance and Electric Interests, from the Underwriter's Standpoint."

The headquarters of the Club are at 7 Park Street, where members will be welcome during their visit to the city.

On Thursday there will be parties organized to visit the electrical factories in the vicinity, and members and friends should avail themselves of the opportunity.

BOSTON, May 17, 1890.

CHICAGO.

The Sprague Electric Road.—To Avoid Manhole Explosions.—Speed in Milwaukee.

THE electric street railway on the west side, which is being built by the Sprague company, is now being rapidly pushed ahead, and work on the power house which is located on Lake street, between Ridgeland and Austin avenues—is going forward as fast as possible. The line starts at 40th street, and runs west on Madison street to Oak Park, then across to Lake street and back east, joining the starting point again. There are about nine miles of road to be equipped of which eight are double track. The road is expected to be in operation by October 1st, and will add greatly to the rapid transit facilities of Chicago.

Improbable as it may seem, things are going too swiftly in Milwaukee, and an ordinance to correct the evil will shortly be presented to the common council. The city never had the reputation of being any too rapid, and the street cars there were supposed to be only a trifle slower than the Supreme Court. But it is the street cars that are too swift now. When the ordinances under which the new electric street railway companies now operate were passed, there never was any idea that street cars could go too fast. It was anything to be faster than the mule teams on the bob-tail cars. The result was the passage of ordinances allowing electric street railway cars to run as fast as possible—the faster the better was the general sentiment when the ordinances were passed. The result is that electric cars are now tearing through the city like a wild steer in a corn field and an ordinance will shortly be introduced which will regulate the speed of the cars, particularly in the business section. Mayor Peck favors such an ordinance and will do all in his power to have the electric cars placed under a control compatible with the safety of passengers and pedestrians.

Commissioner of Public Works Purdy has sent to all underground wire companies in Chicago, a communication requesting them to take the necessary precautions to prevent explosions in man-holes. Mr. Purdy suggests that the companies consult Prof. Barrett, who has devised a means of preventing such explosions.

CHICAGO, May 16, 1890.

ST. LOUIS

Electric Railway Work.—New Western Union Office.—St. Louis Conduit Company.

THE Missouri Railroad Co. and the Forest Park, Laclede and Fourth Street Railroad Co. have jointly closed a contract with the Thomson-Houston Electric Co. for the equipment of 15 miles of road and 36 motor cars. The Market street line of the Missouri Co. will be extended from Tower Grove station on the Missouri-Pacific Railway to Shaw's Botanical Garden and Tower Grove Park. The Missouri Railroad Co. have increased their capital stock from $900,000 to $2,400,000.

The Southern Railroad Co. have contracted with the Thomson-Houston Electric Co. for 24 motor cars. Relaying and wiring of track is now going on from both ends of the road, and poles are being erected on the up-town end. The road has a mileage of eight miles of double track extending from Market street to Carondelet. A bill has been introduced before the Municipal Assembly authoring this company to operate its road north of Market street by electric power.

The new power station of the St. Louis Electric Power Co. started up last Friday, the 5th. The station is located on Morgan street, between 2d and 3d, and consists of a substantial brick building, one story in height, covering a ground space 63 x 108. The boiler room 63 x 48, contains two tubular boilers 66 x 16, aggregating 250 h. p. The dynamo room contains one Westinghouse engine of 125 h. p., and one Russell engine 150 h. p., one 80,000 watt and four 30,000 watt Edison dynamos.

The Western Union Telegraph Co. have taken a 25 year lease on the Lucas Building, at a rental of $4,500 per annum. The telegraph company are to expend $20,000 on the building. The building is four stories high, has a frontage of 40 feet on Pine street and a depth of 140 feet, with a city alley on one side and a private alley on the other side.

The St. Louis Conduit Co. has been incorporated with a capital stock of $250,000. The incorporators are John M. Sellers, Jacob C. Ewald and Henry W. Bond.

ST. LOUIS, May 14, 1890.

PITTSBURGH.

Police and Fire Bureau Wires.—Lighting the City of Allegheny.—Stanley-Slattery Litigation.—Electric Mining in West Virginia.

THE wires of the police and fire bureau are to be changed in this city. Supt. Mead, of the department of electricity, has just been allowed to spend $3,000 in making the change. He says that the large number of electric railway wires in the city has greatly interfered with the telephone system and something had to be done to prevent their entire uselessness. Mr. Mead intends to substitute two twisted wires, where one is now used, and he hopes to thus obviate any further trouble.

The Westinghouse electric light plant in the city of Allegheny, is rapidly nearing completion. All the towers, and there are to be 52 of them, are almost put up, as well as the mast arms for the arc lights and it is expected that the plant will be in active operation July 1.

Judges Bates, Clark and Stocking rendered their decision a few days ago in the Stanley-Slattery litigation case regarding a patent on alternate current system of electrical distribution. Mr. Stanley's patent belongs to the Westinghouse Electric Co. and Mr. Slattery is the electrician of the Fort Wayne Electric Co. In their decision, the judges stated that they believed Mr. Stanley to have conceived of the invention and brought it into commercial utility before Mr. Slattery reduced it to practice. This confirms the decision rendered some time ago by Commissioners Johnson and Morris.

The first electric mining plant in the state of West Virginia, was put up a few days ago at Thurmond, Fayette county.

PITTSBURGH, May 17, 1890.

THE NATIONAL ELECTRICAL MANUFACTURING CO., the successors to the electrical department of the New Haven Clock Co., moved to their new quarters, 14 and 16 Vesey street, on May 12.

LITERATURE.

Electrical Engineering for Electric Light Artizans and Students: By W. Slingo and A. Brooker. London and New York. Longmans, Green & Co., 1890. 307 illustrations, 631 pages. 4⅛ x 7⅛. Price, $3.50.

THE Admirable Crichton of the electrical field is rapidly becoming as extinct as the dodo. There was a time, and not long ago, when a man might fairly claim with an easy conscience and a cheek of ordinary hue that he was familiar with the whole round of electrical science and invention. To-day work as he will, and even though he possess the memory of a Macaulay or the assimilative powers of a Webster, or the quick grasp of fundamental principles of a Faraday, he must admit that in some departments of the vast field of electrical knowledge his training and expertness are superficial. In fact the whole drift of his work, if he aims at success, will be distinctly towards specialization.

Nevertheless, and because of this state of affairs, the need grows for comprehensive treatises on electricity, of a kind that an intelligent student may readily master, so that even if he does not come in actual contact with the apparatus and appliances described, or does not have occasion to employ in their most perfect outworkings the principles enunciated, he has a tolerable familiarity with the subject, and is able to follow with appreciation all the work that is being done.

The present work is a highly creditable example of the modern electrical compendium and encyclopædia in brief, and may be given to any student or workman with confidence as to the good results it will produce. It ranges over the whole field and no subject is touched upon that is not rendered intelligible and interesting. No one can read this book through with mind intent and desirious of learning, who will not be able thereafter to think and speak intelligently of well nigh every branch of heavy electrical engineering recognized to-day. It does not, however, include telegraphy or telephony. There is warrant for this, but we think that these two fields of work have some claim to recognition under the generic title of the book.

In view of the variety of subjects touched upon, the work is remarkably free from mistakes. We must take exception, however, to the statement on page 546, that the Edison lamp is rarely used now. As every body knows, there are hundreds of thousands in use in America, the number growing yearly. Even if the statement were meant to apply to England it would not be true, because such lamps as are made there are virtually all made under Edison patents to a greater or less degree. With regard to electric railway work, the book is also a little deficient and inexact. While the enormous development in America is hardly noticed, Holroyd Smith's work, and that at Northfleet comes in for extended description. Now it is quite right to give Holroyd Smith and Northfleet their due, but the work done in America is of vastly greater importance.

These are details, however, and are more than offset by many excellences, not the least of which is the careful enunciation of principles and fundamental ideas, and a trustworthy exposition of the latest teaching on moot points. The book is beautifully printed, and has an index that will stand testing.

SOCIETY AND CLUB NOTES.

NEW YORK ELECTRICAL SOCIETY.

THE annual meeting of the New York Electrical Society was held at Columbia College on May 15, when the secretary, Mr. G. H. Guy read his annual report, and officers were elected. The report is as follows:

The work of the Society has been steadily progressing during the past year. The number of members now on the roll is 250. During the year 40 new members have been elected, and there have been four resignations, so that the net gain in membership is 36.

The Society has been able to provide an excellent course of lectures, which have not only been received with appreciation by the members and their friends, but have secured from the press a recognition which is gratifying and encouraging.

A recapitulation of the subjects treated of at the various meetings will enable you to judge of the manner in which the Society has endeavored to carry out its work.

Mr. W. J. Jenks gave a paper on the "Practical Working of the Edison Three-wire System;" Mr. A. A. Knudson spoke on "Electrical Exhibitions," and Mr. Joseph Wetzler told of what they are doing in electricity in Europe. Our worthy president lectured on "How to Test Electrical Motors;" Mr. S. Dana Greene gave us "The Development of Electric Street Car Traction;" Mr. Joseph Wetzler ushered in 1890 with his lecture on "The Electrical Progress of the Year," which has now become a recognized feature in the Society's programme. Mr. Herbert Laws Webb broke new ground in his paper on "The Construction and Laying of Submarine Cables," and a very full house attended the "Phonograph Evening." Mr. T. C. Martin read a paper on

"The Social Side of the Electric Railway." In consequence of the number of inquiries about this paper, the society has been induced to publish it, and several thousand copies have been sold at cost, to the leading electric railway companies in the country, for missionary purposes. By way of giving a practical exposition of the alternating current, a subject that is now attracting such universal attention, the Society called its members together one evening at the Equitable Building, and the Westinghouse company made them welcome at its exhibition plant there. The last meeting was held at the Lenox Lyceum, to inspect the fine collection of Edison inventions and apparatus, and a large number availed themselves of the opportunity of seeing the beautiful electrical exhibition there.

For the next season the executive committee has in contemplation plans which it is hoped will more than maintain the prestige and influence which the Society has so honorably gained during its many years of existence as the oldest body of the kind in the country. In the course of lectures that will be provided, the Society will engage the subject of electricity on its popular and educational side. There is now a great popular demand in this city for information on everything that pertains to electricity, and the Society stands between the electrical inventor and engineer, and the public, helping alike the student who knows something of electricity, and the citizen who knows nothing at all, and feels helpless in his ignorance.

There is a wide educational field open, and in this field the Society proposes to largely increase its work.

I cannot close this report without a reference to Columbia College, in whose hall we meet to-night. It is gratifying to see that this seat of learning is discharging its duty to the fullest degree when, in addition to following out the developments of higher education it places itself in touch and closest intimacy with such a Society as this, which seeks to make the latest researches of the scientist and the investigator common property and a benefaction to all

The Society feels deeply grateful to Columbia College for the hearty encouragement and support given to it, and trusts that the ties thus formed may increase and be strengthened.

Prof. F. B. Crocker was re-elected as president. Messrs. J. Wetzler, Francis Forbes, Dr. O. A. Moses, T. C. Martin, G. H. Stockbridge and E. L. Bradley, were elected vice-presidents, the first three being re-elected. Secretary G. H. Guy and treasurer H. A. Sinclair were re-elected. Messrs. C. O. Mailloux, J. Wetzler and F. B. Crocker were elected as trustees.

After this business had been dispatched, Mr. J. J. Carty, electrician of the Metropolitan Telephone and Telegraph Company, read a most interesting paper on "Telephone Engineering," which will be found elsewhere in our columns. It elicited an instructive and lively discussion, in which Messrs. Wintringham, Hammer, Pupin, Moses, Mailloux, Wetzler and several others participated.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued May 13, 1890.

Alarms and Signals:—*Fire-Alarm Regulator*, C. J. Spike and H. V. McLeod 427,711. *Electric Signal*, J. Haas, Jr., 427,762.

Clocks:—*Electro-Pneumatic Clock System*, C. A. Mayrhofer, 427,781.

Conductors, Conduits and Insulators:—*Electrical Conductor for the Transmission of Power*, W. J. Cordley, 427,746. *Terminal for Electric Cables*, J. A. Hanagin. 428,046. *Manufacture of Telegraph Cables*, W. R. Patterson, 428,055.

Distribution: *System of Electrical Distribution*, L. Bell, 427,541. *Alternating Current Apparatus*, E. & F. W. Heymann, 427,571. *Electrical Converter*, S. Z. de Ferranti, 427,751.

Dynamos and Motors:—*Carbon Brush for Motors*, L. Daft, 427,674. *Alternating Current Motor*, M. Von Dolivo-Dobrowolsky, 427,978. *Commutator-Brush*, E. H. Bowen, 428,038.

Lamps and Appurtenances:—*Incandescent Electric-Light Bulb*, T. B. Atterbury, 427,951. *Lantern for Electric Arc Lights*, J. W. Gwinn, 427,986. *Arc Lamp*, P. Lange, 428,008.

Measurement:—*Electric Meter*, S. C. C. Currie, 427,748. *Method of Measuring and Registering Electric Energy*, S. C. C. Currie, 427,749.

Metal-Working:—*Method of Electric Welding*, C. L. Coffin, 427,971.

Miscellaneous:—*Lightning Arrester*, L. Bell, 427,540. *Fuse-Block*, C. F. Brush, 427,548. *Electric Prod-Pole*, J. M. Burton, 427,549. *Electric Heater*, B. C. Howard, 427,574. *Electro-Magnet*, F. J. Patten, 427,606. *Electro-Matrix Machine*, G. A. Goodson, 427,681. *Automatic Electric Cut-Out*, E. M. Bentley, 427,724. *Fuse-Plug*, W. A. Anthony, 427,823. *Automatic Lightning Arrester*, C. M. Griffin, 427,984. *Method of Producing Alternating Electric Currents*, M. S. Conly, 428,042. *Ground Detector*, C. H. Macloskie, 428,050. *Pyro-Magnetic Electric Generator*, N. Tesla, 428,057.

Railways and Appliances:—*Trolley Arm for Electric Cars*, W. F. Harriman, 427,569. *Guide for Trolley-Wheels*, H. A. Marks, 427,589. *Trolley or Collecting Wheel for Electric Railways*, S. H. Short, 427,628. *Electric Railway*, E. M. Bentley, 427,725. *Contact Device for Electric Railways*, E. M. Bentley, 427,726. *Electric Circuit Closer for Railway-Signals*, F. E Morgan and F. A. Lane, 427,783. *Electric Train-Signaling Apparatus for Railways*, E. J. J. de Baillehache, 427,958. *Motor-Car*, G. M. & J. A. Brill, 427,966. *Track-Instrument for Railroad-Signals*, M. S. Conly, 428,041.

Secondary Batteries:—*Composition for Supports for Secondary Battery Electrodes*, W. F. Smith, 427,710. *Secondary Battery Electrode*, J. F. McLaughlin, 427,785. *Secondary Battery*, T. F. Nevins, 427,789.

Telegraphs:—*Telegraph Key*, J. S. Kaylor, 427,876.

Telephones and Apparatus:—*Multiple Switch-Board Test System*, C. E. Scribner, 427,621. *Switch-Board*, C. E. Scribner, 427,622. *Test-Circuit for Multiple Switch-Boards*, C. E. Scribner, 427,623. *Multiple Switch-Board Test-Circuit*, C. E. Scribner, 427,624. *Telephone Exchange Apparatus*, J. J. Carty, 427,742. *Multiple Switch-Board*, C. E. Scribner, 427,917. *Means for Effecting Communication in Telephone Systems*, L. J. Crossley and W. Emmott, 427,974.

PATENT NOTES.

PROF. FORBES' CARBON BRUSH.

THE issuance of a patent on the carbon brush as employed so extensively for dynamos and motors at the present time has created considerable interest. The patent which was granted to PROF. GEORGE FORBES, of London, describes a brush composed of carbon electro-plated with copper and strengthened by a backing of copper. The patent, entitled "Electrical Collecting Device" No. 427,259, was issued on May 6,1890, and its claims are as follows:

1. A contact maker or brush for establishing electrical connection with parts in rapid relative motion—such as the collectors of dynamo-machines—consisting of a plate of carbon, substantially as described.
2. A contact maker or brush for establishing electrical connection with a rapidly-moving contact-surface of metal, consisting of a carbon plate.
3. A contact maker or brush for establishing electrical connection with a rapidly-moving contact-surface, consisting of a plate of carbon backed with metal, substantially as described.
4. In combination with the commutator or collector of an electric machine, a contact-brush consisting of a plate of carbon and a metallic coating electro-plated thereon.
5. A commutator-brush for a dynamo-machine or electric motor, consisting of a plate of carbon and a metallic coating electro-plated on said plate, substantially as described.
6. A commutator-brush for a dynamo-machine or electric motor, consisting of a plate of carbon, a metallic coating electro-plated thereon, and a metallic plate fastened to such electro-plated coating.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

COOLING THE STAR THEATRE, N. Y., WITH CROCKER-WHEELER MOTORS.

MR. THEODORE MOSS, proprietor of the Star Theatre, corner of Broadway and Thirteenth street, after considering various plans for cooling the auditorium of the theatre during the performances in the summer months, has adopted the plan submitted by The Crocker-Wheeler Electric Motor Co., of Fourteenth and Washington streets, through Mr. McCoubray, their secretary and general sales agent. A trial of the apparatus on Monday, May 12th, in the presence of Mr. Moss and his staff, demonstrated the complete success of the plant, and the patrons of the theatre during the warm weather will find the temperature as pleasant as may be found at Newport, no matter what the temperature may be on the outside.

The plant consists of a large Crocker-Wheeler electric motor and an immense pressure blower—an ice-chamber of tremendous proportions—various ducts leading to the auditorium, and numerous registers for controlling the flow of air. One of the peculiarities of the system is the construction of the ice-chamber, which is so arranged that the drippings of the water from the ice are utilized to cool the air before it comes in contact with the ice itself.

The system is an assured success, and will keep the atmosphere of the theatre in a delightful condition, even without the use of ice. It is proposed to use ice, only when necessary, in extremely hot weather.

When it is considered that a volume of 25,000 cubic feet of air per minute at a temperature much lower than the outside air, is forced into the auditorium, we are constrained to believe that we can take our pleasure at home instead of being forced to the sea-shore.

It is believed, too, that this is but the foundation of a system by which cool air will be delivered into houses throughout cities and towns as we now receive our water, our light, our gas, and our heat. When the several small electric fan motors ordered by Mr. Moss (and which are a part of the system) are placed in position, the plant will be complete as designed by Mr. McCoubray.

THE COMPLETE ELECTRIC CONSTRUCTION COMPANY.

This company has been driven by the growth and pressure of its business to take larger quarters, and has moved into 24 Cortlandt street, where it has engaged the whole first floor, stretching clear through to Dey street upon which it also has an entrance. The floor is being divided off into departments. Mr. Seely and Mr. Taylor have their office and clerical force in front, overlooking Cortlandt street. The book-keeping force is at the Dey street end, and the underground department has quarters midway between. Racks are provided for plans, etc. of all the work done or in hand, and all classes of supplies are conveniently placed in bins and lockers. The company has been doing an enormous business and considers it nothing unusual to have as many as 300 men occupied at once on its various installations. The Seely & Taylor Manufacturing Co. is also located at No. 24, and is getting ready to meet the inevitable big demand for its rubber molding and other ingenious and patented specialties.

H. E. & C. BAXTER.

THE above well known firm, of 18 Fulton street, Brooklyn, manufacturers of electrical goods, have just issued a new and very tasteful catalogue and price list of their annunciators, bells, electro-magnets, push buttons, batteries, zincs, name plates, letter boxes, burglar alarm window springs, &c. Their iron box bells are well illustrated and described, and merit the notice of all buyers of this line of supplies. It will be remembered that in the Baxter hotel annunciators, of which cuts are shown, the gravity drop is used, for which many advantages are claimed on account of the absence of springs and the simplicity of construction. The goods of the firm are noted for their handsome design and excellence of workmanship, and there can be no doubt that this catalogue will help to stimulate the demand for them.

NEW WESTINGHOUSE PLANTS.

LOS ANGELES, California, the beautiful "City of the Angels," is to have a new electric lighting plant, and the Company use the Westinghouse alternate current system. The initial capacity of this plant will be fifteen hundred 16 c. p. lamps, and the work of construction is to begin immediately. Los Angeles is in many respects a paradise, but of course is not exempt from the darkness which visits every corner of the globe for a portion of each day. The capitalists of the city are wise to invest their money in furnishing electric illumination and their enterprise will certainly be appreciated.

LAS VEGAS, New Mexico, might be called an out of the way town. But evidently it would be unjust to charge the citizens of the place with lack of enterprise. A company has been formed there to go into the electric lighting business and a representative of The Westinghouse Electric Company recently sold to it a five hundred light incandescent machine of this company's manufacture together with one of the new alternate current arc lighting dynamos of forty lights capacity.

YOUNGSTOWN, Ohio, is to adopt the alternating current incandescent system. The Westinghouse Electric Company recently sold to a newly formed corporation in that thriving young manufacturing city a twenty-two hundred and fifty light plant. It is the intention to push the work of installation to completion with the least possible delay.

THE VENEZUELA & ELECTRICAL APPLIANCES COMPANY.

THE Venezuela & Electrical Appliances Company (limited) is bringing out its securities in London. It is the purchaser of the franchise, etc., of the Intercontinental Company of Boston, as lately stated. The Venezuela company has a capital of £70,000, £1 shares, which it issues, with £70,000 5 per cent, first mortgage bonds, the latter at 85 per cent. It pays the Intercontinental company, according to the prospectus, £55,000 of the bonds and £60,000 of the shares or the proceeds thereof.

ALTERNATING ARC LIGHTS.

THE Westinghouse Electric Company has issued a very handsome and complete illustrated pamphlet on its new alternating arc lighting system. The descriptive matter is excellent, and the cuts are of the first order of merit. The cover is handsomely embossed and silvered.

THE TROPICAL AMERICAN TELEPHONE COMPANY.

THE Tropical American Telephone Company has closed a contract with the governor-general of Cuba for 100 sets of instruments and a large lot of supplies, the Cuban government having taken over the telephone business formerly operated by the Compania Electrica de Cuba. An order for 500 complete sets has also been received from Rio de Janeiro.

The Tropical company have just issued a very important pamphlet on "Telephone Rights," and a careful perusal of this is recommended to all exporters of telephonic apparatus. It will be seen that the Tropical company have the *exclusive* right to sell genuine Bell telephones in Central America, South America and the West India Islands, and all companies exporting instruments to these countries have "got to buy" their apparatus from the Tropical company whatever reports may be made to the contrary. The American Bell Telephone Company continue to supply the Tropical American Telephone Company *exclusively* with instruments for the above countries, as it did the Continental company originally.

THE NEW YORK INSULATED WIRE COMPANY.

AFTER a trip of unusual length, and corresponding success, Mr. J. W. Godfrey, the general manager of the above company, has returned home to headquarters at 649 & 651 Broadway, this city. He reports an excellent condition of trade through the west, and has done much in the way of establishing the new agencies necessary to handle and distribute the large amount of wire, cable, tape &c. now called for. The list of selling agents now comprises the following: Southwestern Electrical Supply Co., Kansas City Mo.; Knapp Electrical Works, Chicago, Ill.; St. Louis Electrical Supply Co., St. Louis, Mo.; the Central Thomson-Houston Co., Cincinnati, O.; Kendal & Slade, Boston, Mass.; Fisher Electric Co., Detroit, Mich.; Dayton, Hall & Avery, Portland, Oregon; Thos. F. Day & Co., San Francisco, Cal.; North-west Thomson-Houston Co., St. Paul, Minn.; Southern Electrical Mfg. & Supply Co., New Orleans, La.; Bagnall & Hillas, Yokohama, Japan.

THE ELEKTRON MANUFACTURING COMPANY.

THE above company, of Washington street, Brooklyn, are enjoying a great run of business, and in order to keep pace with the demand for their motors and dynamos have been compelled to enlarge their factory and increase their facilities for production. Their motors are being used to-day upon work of the utmost variety and the testimonials as to their merit are neither few in number nor ambiguous in tone. Mr. E. H. Cutler, the treasurer and manager, has in hand a very interesting pamphlet on their Perret motor and its uses in connection with primary and secondary batteries or with dynamo current. The company's slow running dynamos have also won hearty approval as generators for light and power, and a specialty is now being made of isolated plants for incandescent lighting. Mr. Perret, the electrician of the company, is engaged upon a number of interesting improvements and developments, all of which will mature in time.

THE NATIONAL ELECTRIC TRACTION SYSTEM.

THE Detroit Electrical Works have been extremely busy equipping roads with the National Electric Traction System worked out by Mr. F. B. Rae, who is well known as one of the pioneer electric railway builders of this country. They have already equipped roads as follows:

Fort Worth, Texas, Land & Street Railway Co., 15 cars, four 50,000 watt generators.

Saginaw, Mich., Union Street Railway Co., East Saginaw, 25 cars, four 65,000 watt generators.

Adrian, Mich., Electric Street Railway Co., four cars, two 35,000 watt generators.

Citizens' Electric Street Railway Co., Elkhart, Ind., five cars, two 35,000 watt generators.

Decatur, Ill., Electric Street Railway Co., 4 cars, two 65,000 watt machines.

They are also equipping the Sault Ste. Marie, Mich., Street Railway with 4 cars and one 65,000 watt generator; the East Detroit & Grosse Point Railway with 6 cars and two 65,000 watt generators; and the Highland Park Railway, Detroit, with four cars and two 65,000 watt generators.

In all the above, the plant has been made large with a view of increasing the car equipment. Mr. Rae is using in nearly every instance a single motor of 30 h. p. geared direct to both axles, and he is satisfied that his method is the most economical as regards first cost and maintenance and in avoidance of friction loss, when compared with any of the double motor arrangements.

P. A. DOWD & CO.

MESSRS. P. A. Dowd and G. W. LaRue, at present associated under the firm name of P. A. Dowd & Co., the well known agents of the Sprague Electric Railway and Motor Co., have mutually agreed to dissolve partnership, to date from June 5.

THE GREAT WESTERN ELECTRIC SUPPLY CO.

Mr. Geo. Cutter has now definitely located his new quarters at 190—192 Fifth ave., Chicago The building which he has leased and which will be filled with general supplies of all kinds "right away," is 42 x 90 feet and comprises five floors and basement and is very desirably situated for the immense business which Mr. Cutter intends doing. One smallitem of three carloads of Simplex wire is already on its way, and Mr. Cutter expects to move in early next week.

Important developments will be immediately made and the business pushed to its fullest extent. Arrangements have been made with a large syndicate which will be named The Great Western Electric Supply Co., to open branches in several important cities, and supplies of the finest class will be carried in stock in large quantities enabling all orders to be executed with the utmost promptitude. We wish Mr. Cutter well deserved success in his new departure, which will be one of the largest ever carried out in the supply business and we are confident that by reason of his large business experience, and executive ability together with his widely known qualities as a "hustler" all over the country, an enormous success awaits him.

THE EASTERN ELECTRIC CABLE COMPANY.

The Eastern Electric Cable Company of Boston have issued a neat little price list of their far famed Clark wires. One of the special features about the Clark insulation is that it is chemically prepared in such a manner that it is perculiarly able to resist all oxidizing. In the price list they call attention for the first time to their latest production, the "Hub" line wire. This wire is designed for use among trees, and wherever a superior line wire is required. The wire is covered with a thin layer of the ordinary Clark compound, and protected by two heavy braids, coated on the outside with a special waterproof solution, which makes it very hard and durable, and capable of withstanding a large amount of abrasion. Modesty has prevented the Eastern Electric Cable Company from appending numerous testimonials, and the pamphlet is entirely devoted to price lists, and a few useful formulae.

TESTED SAFETY FUSES.

With the view of determining the "safety" of the fuses and fuse wires now on the market, the Massachusetts Electrical Engineering Co. have made a series of elaborate tests on them. The results of one series of these tests and the conclusions reached were published in this paper last week.

The company now places on the market, through its supply department, a fuse which, it claims, fills the requirements of a safety fuse. That is, its fusing point is independent of the surrounding temperature, or of its position (open air or closed box). The disadvantages which it has been the aim of the designers of this fuse to overcome are the variation of fusing-point with length, position, and temperature of surrounding air, as well as the violent spluttering and throwing of melted metal. These new fuses are called the "American Safety Fuses." They are made of a strip of an alloy foil, mounted on asbestos, and coated through the centre on the foil side with an asbestos compound.

The exposed portion of the foil is thus surrounded by asbestos, which prevents any loss of heat by radiation when heated by an undue increase in current. The centre of the foil becomes the hottest, and the foil breaks without injuring the binding posts or even breaking the asbestos support.

These fuses are packed in boxes of 100 each, of various lengths and grades. They are carefully tested and the boxes marked with the results of the tests. At present the company are not making these foil fuses in the larger carrying capacities, but are supplying in all sizes a superior grade of tested fuse wire. Each spool of this wire is tested at several points, and a certificate accompanies each coil or spool sold, giving the following data:

Advisable carrying capacity:—
 Fusing point in open air of a 1 inch piece.
 Fusing point in open air of a 2 inch piece.
 Fusing point in closed box of a 1 inch piece.
 Fusing point in closed box of a 2 inch piece.

THE EVANS FRICTION CONE.

The Evans Friction Cone Company continue to receive the warmest testimonials of their friction system of driving dynamos direct from engines. In a letter recently received from the Hutchinson Light and Power Company, of Hutchinson, Kans., where they are using the Evans system, the manager writes that he is more than satisfied with the result, and he points out several important features. He can use two dynamos on one engine, and yet shut down any one dynamo, without interfering with the other. A dynamo can be stopped more simply than by clutches; there is no lost motion even under full load, and the pressure on the bearings is even less than if belts were used. Mr. L. A. Beebe of the Morgan Engineering Company, of Alliance, O., who has been using the Evans system for some time on a few of their dynamos, writes that he now intends to use it on all. The new station of the Attleboro Electric Light Company, Attleboro, Mass., using the Evans system, has now been started up, and the writer had the pleasure of seeing the system in use a few days ago. Besides running electric light dynamos, the two generators for the electric railway are also driven by the Evans system, and Mr. H. M. Daggett, Jr., states that he is entirely satisfied with it.

NEW ENGLAND TRADE NOTES.

J. A. Grant & Company, of Boston, have sold a 500 h. p. McIntosh & Seymour engine for the St. John Electric Railway Company, St. John, N. B. The railway system is being changed from horses to electric power, though the system has not yet been fully decided. The McIntosh & Seymour engine is meeting with great success in New England as an economical and reliable machine, and Messrs. Grant & Company are finding a large field for them among the numerous electrical enterprises.

The West End Street Railway Company have given permission to Mr. W. D. Swart to put in on their system one of his automatic electric switches, a model of which is to be seen in the office of the Wheeler Reflector Company of Boston. The action of the switch depends upon an electro-magnet under the surface of the street, operated by powerful electro-magnets carried on the car.

The Connecticut River Railroad are running a train lighted throughout by electricity. The Barrett system of storage battery is used, and Jordan train couplers connect the different cars.

The Standard Electric Company of Vermont has sold a 200 light dynamo for use on board the S. S. "Winthrop," a steamer running between Bar Harbor and New York.

Brown Electric Protector Company.—Mr. W. H. Smith of this company has just filed patent papers for a new and improved device to be applied to the Brown protector when used on metallic circuits. By means of the device, should a wire between any two instruments which are protected become crossed with an electric light or power wire, it is immediately cut out, and a ground circuit is used in its place between the two instruments, thus enabling the circuit at all times to be serviceable.

Beacon Vacuum Pump and Electrical Company has been organized in Boston with a capital of $1,000,000, with Mr. Jacob Heilborn, president, and Mr. Lewis E. Whicher, secretary and treasurer, and a strong board of directors. The company has been formed for the purpose of developing the Berrenberg vacuum pump, recently described in The Electrical Engineer, which is attracting a great amount of attention from all manufacturers of incandescent lamps. The company are now making arrangements for a factory for the manufacture of these pumps.

Mr. L. H. Rogers, New England agent of the Brush Electric Company, has sold a 30-light Brush dynamo with lamps of 2,000 c. p. to the Burlington Gas Light Company, of Burlington, Vt. There are now eight Brush dynamos in all in this station.

WESTERN TRADE NOTES.

Shay, Stephens & Co., 134 Van Buren street, manufacturers of insulators and battery jars, are doing a large amount of business with the electrical trade. Their insulators are of a special grade of glass and give a very high insulation and are also remarkably durable. They propose to push this branch of their business with the utmost vigor, which will be easy we opine from the fine class of goods which they are making and which have given such excellent satisfaction heretofore.

Noyes Bros., 85 Fifth avenue, Chicago, are turning out some very handsome electroliers which show remarkable taste and beauty in their designing. Their fixtures are in large demand and have been used in a large number of plants.

Mr. W. H. McKinlock, president of the Central Electric Co., has gone East on a short business trip. He will not return without numerous orders for his company's specialties which are now so well known in all parts of the country.

Mr P. C. Burns, the treasurer of the Findlay Glass and Carbon Co., of St. Louis, was in town last week looking after the interests of the company. He made his headquarters at Mr. C. H. Cone's office on Adams street, the well-known representative of the company in this city.

The Knapp Electrical Works, 54 Franklin street, were visited last week by fire which occured about 2 o'clock in the early morning of the 13th and burned out the second floor of their fine building. The machinery located there was badly damaged. It is understood that the damage is fully covered by insurance. The extent of the loss is not yet known.

Mr. George Kelly, 211 Randolph street, manufacturer of the World's Fair wire link belt, which is meeting with good success, and is especially adapted for work in very hot places, has moved his offices to more commodious quarters on the second floor. He also makes a specialty of wire link matting, and his floor is carpeted with handsome and fanciful designs in mats. These mats are remarkable for their durability.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. IX. NEW YORK, MAY 28, 1890. No. 108

Study science with earnestness—search into nature—elicit the truth—reason on it, and reject all which will not stand the closest investigation.—Faraday.

THE BOSTON MEETING OF THE ELECTRICAL ENGINEERS.

SINCE its inaugural out of town meeting, held in Philadelphia in 1884, the American Institute of Electrical Engineers has held its sessions in this city; but in recognition of the national character of the organization, the managers very wisely determined to inaugurate the seventh year's work of the Institute by following the practice of the other representative engineering societies of the country and arranging a meeting away from home. The large New England membership of the Institute made the selection of Boston for the meeting place an eminently proper one, and the success which attended the meeting is evidence of the felicity of the choice. In regard both to the excellence of the papers presented and the attendance, the Boston meeting compares favorably with any ever held by the Institute. But when to this we add the opportunities offered by the second day devoted to excursions, following after the other courtesies extended, we have no hesitation in saying that the Boston meeting was the most successful of any thus far to the credit of the Institute. The members of the electrical fraternity of Boston vied with one another in their attempts to make the visitors feel at home. The Boston Electric Club is especially entitled to the kind remembrance of the visiting members and its hospitable entertainment was one of the most pleasant features of the meeting. The West End Street Railway Co. and the Thomson-Houston Electric Co. also deserve the warmest thanks of the Institute for the opportunities offered for the inspection of the largest electric railway system in the world and one of the largest electrical manufacturing establishments in existence. When we add to this the courtesies extended by the Massachusetts Institute of Technology, it will be admitted that the Institute's choice of Boston was no mistake. Now that the practice of holding migratory meetings has been so happily tried again, it is to be hoped and expected that they will be continued at stated intervals, so that as many of the members as possible may be brought together to discuss plans and exchange experiences, and make new acquaintanceships.

STEAM AND ELECTRICITY ON RAILROADS.

Now that the economy of electric street railways may be said to be definitely settled, the electrical engineer already looks forward to the time when he will be called upon to attack the problem of converting our great trunk railways into electric transportation lines. This consummation has indeed long been a favorite theme for speculation, and though its accomplishment has in a general way been admitted to be possible, it was obvious to the engineer that the conditions of the competition, as it were, are quite different from those which the electric motor encountered in its contest against the horse or mule. In the latter case the result was but a repetition of the defeat of animal power by specially designed machinery with steam as the source of power. But when we come to consider the case of the supplanting of the independent steam locomotive by electricity we encounter the change from one type of steam engine to another, but with the addition of intermediary conversions of power into current and vice versa. Evidently then these conditions are quite different from those which electricity has already successfully overcome, and the recognition of this fact will go far towards the prevention of mistakes which are the result of enthusiasm unchecked by the sober contemplation of the conditions involved. The exact nature of the conditions, though hinted at in a general way, had not up to the present time been reduced to that definiteness which would entitle them to be considered as engineering data, and it is therefore a matter for congratulation that to the engineering profession at large a thorough discussion of this subject is made accessible by one whose previous training and work in this field at once gives his results the stamp of reliability as based on present practice. We refer to the admirable paper presented by Mr. O. T. Crosby before the American Institute of Electrical Engineers, in Boston, in which the subject under discussion is treated in its various practical bearings. The all-important question of the possibility of taking off the current from the conductors at high speeds having been successfully settled, Mr. Crosby enters into the discussion of the main questions as to the relative cost of power and operating expenses, generally, under various assumed conditions of practice, in which some very interesting relations are brought out as to the cost of power, in which, as was to be expected, the efficiency of the electric system plays a prominent part. The conclusions at which Mr. Crosby arrives are of the most encouraging nature and would seem to show that there is as great a future for the electric locomotive on the trunk line railway as there is on the street railway. With the experience gained in the latter work, that of the heavier, to come, will be greatly facilitated, and the attachment of the armature directly to the axle, which seems imperative for economy, will at once remove a fruitful source of trouble. Looked at it in its entirety, there appears to be nothing involved in the problem of general railway transportation by electricity which cannot be successfully met and solved, in the light of past experience, and success will therefore depend only on the application of correct engineering and right economic principles such as those so graphically brought out by Mr. Crosby.

ARC LIGHT CARBON TESTS.

More than ten years have now elapsed since arc lighting took its place among the recognized modern industries, but the changes and improvements which it has undergone have been few as compared with those in the incandescent lamp industry. The fact is apparent, however, that arc lighting is again attracting some of the attention which it formerly engaged almost exclusively. We have but recently had occasion to refer to a striking example of modern arc dynamo design, and are now reminded of the good work that can still be profitably bestowed on that most important element of an arc light system, the carbon pencil. The full importance of this item is aptly shown in the admirable Institute paper of Mr. L. B. Marks. Treating the subject from every standpoint involving economy in practical operation, he has shown in what manner and to what extent the character of the carbon, and especially its method of manufacture, influences its life and efficiency. It would lead us too far to enter into a detailed enumeration of the many points brought out by Mr. Marks, but we fancy that every arc light station superintendent will be stimulated to undertake for himself the determination of the carbon best suited for his circuits. Such a determination in one notable instance cited, resulted in the saving of considerable power and money. While the tests of Mr. Marks seem to fix very clearly the relative positions as to economy under varying conditions of use of the molded and forced carbons as made at the present day, it will probably be some time before the facts brought out will become generally recognized and action be based thereon. It is to be regretted that fuller details as to the exact ingredients of the carbons tested were not forthcoming. This, it seems probable, would have shed additional light on the differences noticed, both in quality, as regards resistance and texture, and in the action of the arc. This lack of information, however, was evidently not due to any oversight of the author, but must be assigned to the natural unwillingness of manufacturers to divulge what may be regarded as valuable trade secrets. Considering the fact, however, that the largest part of the carbons produced in this country at the present time are made from petroleum coke or some residue of petroleum distillation combined with some cementing material, the results obtained may probably be taken as due to carbons of fairly uniform composition. A survey of the literature on this subject stamps Mr. Marks' paper as one of originality and well directed research, which cannot fail to have its effect on this important branch of the arc lighting industry.

THE GLUE POT RISK.

In a paper read before the North Carolina State Firemen's Association last week, Mr. A. R. Foote took occasion to give that body some useful elementary information in a popular form as to the nature of electricity and of the dangers to firemen from electric light wires in buildings. The opportunity was a good one to clear electricity from the obloquy heaped upon it by a sensational press and by interested persons, and Mr. Foote in his wonted neat and epigrammatic manner brushed away the misstatements and misconceptions that have been so readily circulated or accepted.

A week or two ago in this city, for example, a committee of the National Board of Underwriters undertook to present as authentic a number of figures on the origin of fires, and went so far as to assert that "electricity was a most prolific source of danger, and its introduction has cost the insurance companies more than any method of lighting heretofore in use."

This report has since been scattered broadcast accompanied by proof sheets of fire tables, including a highly colored pyramid whose object is to present graphically the dangers of electric lighting. Mr. Foote analyzes the figures and shows that one single fire due to a glue pot did more damage than all that were attributed to electricity, even admitting that the charges against the wires were all well founded. In other words, and stated plainly, the assertions made by the committee were quite without foundation and the gaudy pyramid was a bald piece of deception.

The figures referred to by Mr. Foote will be found in the paper read by Mr. S. E. Barton last week in Boston at the dinner given by the Electric Club to the American Institute of Electrical Engineers. As Mr. Barton shows, the statement made by the committee in question, which by the way, seems to have consisted of one man, was a deliberate misrepresentation. His characterization of it that "it is shamefully unfair because it is untrue," stamps it as it deserves; and his careful review of figures from the same source proves that electricity instead of being the worst, is the best risk element that the underwriters have to deal with. Why cannot we be entertained with some breezy newspaper talk about the "deadly glue pot," if only for a change?

Electric Lighting In The Tropics.

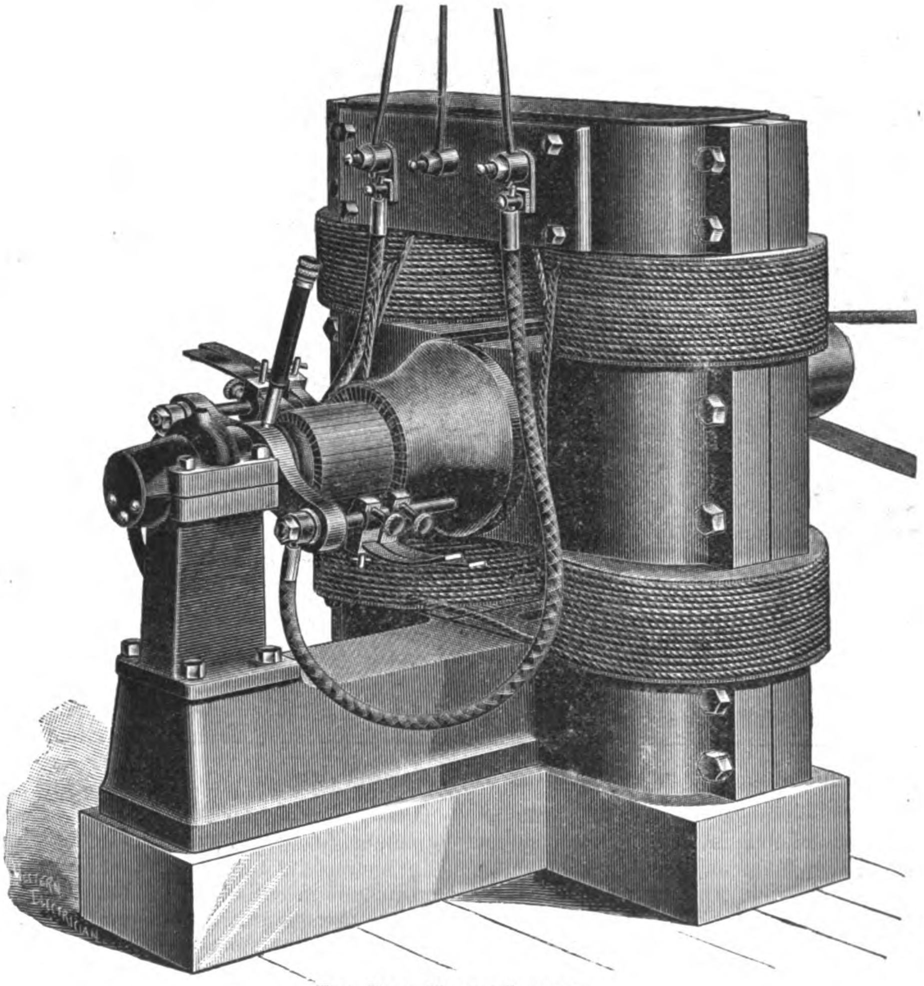
The paper on the above topic, read by Mr. W. H. Fleming before the American Institute of Electrical Engineers, gave in a chatty form no small amount of hard won experience.

They who have been engaged, like Mr. Fleming, in the tropics, know how difficult it is to keep a mechanical or electrical plant up to the right point of efficiency. One of the troubles is the securing of trustworthy help, and perhaps not the least among the others is that of fighting off the lassitude caused by the everlasting heat, which tempts to the habit of letting things go their own way. Still the rewards of electrical work in the tropics should not be small. The light is peculiarly adapted to hot climates and fair prices can generally be obtained. We believe that in the near future the electric motor will also come extensively into demand there, for stationary power purposes and for the operation of street railways.

THE BAIN MOTOR-DYNAMO.

Mr. Foree Bain, of Chicago, has recently designed and put on the market the motor-dynamo which we illustrate herewith. The cut is made from a 7 h. p. motor recently installed in the water-house of the Chicago Paper Co. The motor is used to operate a large freight elevator and a paper cutting machine, and it should be entirely satisfactory to the purchasers, a recent test showing, it is said, an efficiency of 95¼ per cent. The field magnets consist of two shafts of Norway annealed iron, one on either side of the armature, equal in length to the total height of the motor. They are clamped at either end by the double yoke pieces and midway between by very heavy pole pieces. This secures a maximum contact between the pieces; the field is of the "consequent pole" type, with two magnetic circuits.

The pole pieces are of equal size and weight, and consequently of equal magnetic density; therefore, the armature is not pulled harder against one side of the bearing than another, but it "floats" in a field in which the magnetic lines are equal and properly distributed. The double magnetic circuits are extremely short. The coils are wound on spools and slipped over the cores. The spools are only three inches long on this size of motor. There is absolutely no loss of magnetism due to false poles, usually produced by bad contacts in field magnet joints. The bearings are self-oiling.



THE BAIN MOTOR-DYNAMO.

The armature produces 1.4 volts per foot of active wire, with inductor velocity of 48 feet per second. The field is maintained with less than one-half an ampere, or 1¾ per cent. of the total current, and a density of about 600 amperes per square inch. The conductors on the armature are figured at a density of 2,700 amperes per square inch. The field resistance is nearly 1,300 times higher resistance than the armature. The motor runs quietly and very near constant speed with variable load.

Mr. Bain calls this type of machine his "motor-dynamo," not that it is a separate motor and dynamo combined in one machine, but that it may be used as either a motor or a dynamo. His machines show equal efficiency when they are used as dynamos. He builds this type of machine in sizes from 5 to 100 horse-power. The larger sizes have a peculiar compound, one of his late inventions, which is not yet quite ready for introduction.

THE PALMER HOUSE STORAGE BATTERY PLANT.

We are indebted to Mr. E. V. Baillard, electrician for the Electrical Accumulator Co., of this city, for some very interesting details of the storage battery plant recently placed by their Western agent, Mr. W. Hood, in the well-known Palmer House, in Chicago.

The plant comprises 120 cells of the 15 h. type, arranged in 3 series of 40 cells each. These give a capacity of 1,000 ampere hours at a normal rate of discharge of about 100 amperes. The cells are charged from a United States (Weston) dynamo, giving 225 amperes at 70 volts, driven by a Westinghouse engine. This plant takes care of 385 lights, scattered about in various places in the hotel, on a number of circuits.

The dynamo is started at noon time and run to supply lights and charge the battery at the same time. When the load of lamps is equal to the capacity of the dynamo, the battery is cut out. As the load increases and becomes more than the capacity of the dynamo, the battery discharges and helps the dynamo, acting as an auxiliary. When the load decreases towards the latter part of the evening to less than the capacity of the dynamo, the battery is charged with the surplus. At midnight the dynamo is shut down, and the battery substituted to take care of the lights until noon next day. In this manner the lights are available for 24 hours, while the dynamo is run only 12 hours. The capacity of the dynamo is, as will be seen, increased to an available output of 325 amperes, or 100 more than its actual output when running. By putting the current not needed for the lights in the battery, the dynamo and engine can be worked at a point near their maximum output, thereby obtaining the highest efficiency.

The switchboard, which is very handy and convenient, is made up mainly of round and flat copper bars taped and painted with P. & B. compound, all held in place by porcelain insulators. Each cell is placed on a tray supported on porcelain insulators and carried by battery stands of special construction, enabling each and every cell to be frequently and easily inspected. Hence the insulation of the plant is very high.

All the circuits, the dynamos and batteries, terminate at the switchboard, where any combination can be made without budging an inch. A voltmeter is arranged so that the pressure can be measured between the various points of the system, also the E. M. F. of the battery. Each series of accumulators is provided with a switch by which the number of cells in series and the E. M. F. can be adjusted as desired; also a variable resistance so that the current can be varied as desired. An ammeter and a two-way switch are also in each series, thus making each series independent of the other. The dynamo has an ammeter and a two-way switch, which enables running the dynamo direct, or to charge battery and supply lights. There is a pressure equalizer in the main lamp circuit. Between the dynamo and battery is an automatic break-switch which breaks current from the dynamo whenever, through any accident, the dynamo is incapacitated.

All these switches can be quickly and easily handled, and any combination made without in any way interfering with the steadiness of continuity of the lights.

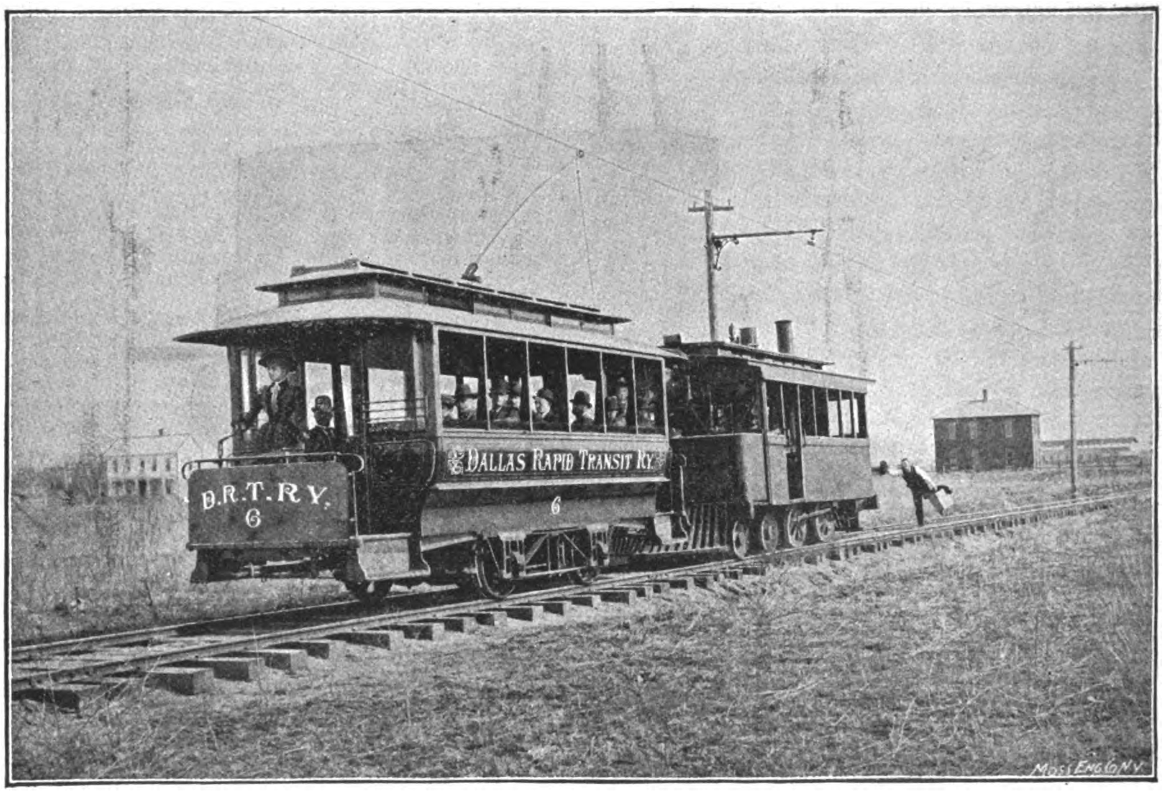
It is fairly to be expected that we shall see many such plants as this in the near future, as they allow a dynamo to be run at its full capacity and highest efficiency, and enable the owner of a building or the superintendent of a moderate sized station to bridge over the hours when the lightness of load would forbid operation at all, or when the plant would be taxed beyond its actual ability.

ELECTRICITY SUPPLANTING STEAM ON THE DALLAS, TEX., RAPID TRANSIT RAILWAY.

The subject of electric railroading has received a great deal of attention in the southwest, and that part of the country is fully awake to the advantages of electric power for car propulsion. The State of Texas has now two electric railways in operation on the Sprague electric system, and others are in course of construction. One of the roads in operation is the Dallas Rapid Transit Railway, a view of which is shown on this page. The motive power for operating the cars on this railway was formerly furnished by a steam dummy, which has now been abandoned for the more modern power.

Our view shows one of the electric cars drawing the old steam dummy. The engraving was made from an instantaneous photograph, and shows the ex-engineer of the steam engine trying in vain to catch the train, which is going so rapidly that he is left behind. An interesting circumstance in connection with this view which shows very clearly the easy manipulation of the electric car, is the fact that the motor car is being operated by a young lady who is in charge of the controlling switch, while another young lady is acting as conductor. By way of comparison it might be mentioned that the steam dummy required an engineer and fireman to run it besides a train conductor on the train.

The electric road has proved very popular in Dallas, and has carried a large number of passengers since its installation. The method of overhead construction used is the single bracket, as shown in the illustration.



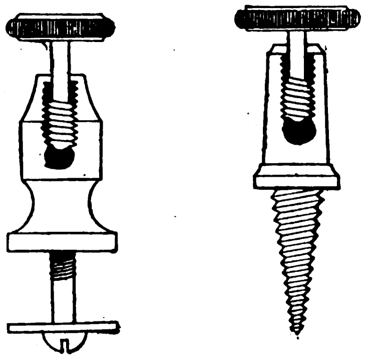
A Trip on the Dallas, Tex., Rapid Transit Railway.

The district messenger boys of New York city have amused themselves during the past week by indulging in a strike, which is said to have come to an early end, but of which reports are still current.

THE DELANY SECURITY BINDING POST.

We illustrate herewith another of the many ingenious novelties that Mr. P. B. Delany amuses himself with producing at his leisure "'tween whiles." Mr. Delany has found occupation for his inventive genius not only in broad methods of telegraph operation but in the countless minor details of familiar apparatus and appliances that are in use every day; and it is to be hoped that he may go on seeking for improvements of this kind.

The article in question, just brought out by The E. S. Greeley & Co., of this city, who have the exclusive rights of manufacture and sale, is the Delany security binding post. It is safe to say that imperfect binding posts have offered as much resistance to the current and as many obstacles to the extended use of electrical appliances as any other single imperfect detail that could be named. The screws have just as great a knack of disappearing as a man's shirt stud has when he is in a hurry to dress. They work loose, jam tight, get lost in transit, shake out, invite the attention of the mischievous; and are often not less a means of torture to the working electrician than the binding post of old was to the unrecanting saints on Scottish sands, or the thumb screws once were to the reserved people who declined to be interviewed.



The Delany Security Binding Post.

A great feature with the new binding post of Mr. Delany is that the screw cannot come out, simply backing far enough to clear the hole, but no further. The thread of the screw is on a shoulder larger than the stem, and as the neck of the cup is turned over tight up to the stem, the screw part cannot pass. The operation is plain and perfect. The binding posts are made in all sizes and shapes. They look just like the ordinary binding posts. It will be strange, indeed, if they do not come into general use, not only for telegraph and telephone instruments and switches, but for all kinds of electrical machinery, including dynamos and electric motors. One great advantage of the new post is that when wiring has to be done in dark and difficult places it can be known with certainty that the wire hole is clear when the screw is withdrawn to the limit. They who have juggled painfully with a set of cells in the recesses of a dark sub-basement or have spent several weary hours in a small cupboard under the office wash bowl, with a one-inch candle as their only companion and consolation, will hail Mr. Delany as a benefactor.

KEMMLER-CASE DELAYS.

It is stated that when the habeas corpus proceedings brought to delay the execution of Kemmler by electricity reach an end (the one still to be acted on raises the question whether the Warden of the prison or the Sheriff of Erie County must be the executioner), the lawyers interested will ask for an injunction on the ground that the particular dynamo that has been set up in Auburn State Prison was sold with a proviso that it was to be used in some other county.

ANNUAL MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The annual meeting of the institute was held at the house of the American Society of Civil Engineers, in this city, on May 20, at 8 p. m., with Vice-President F. R. Upton in the chair. There was a large attendance.

Secretary Pope presented his report showing a prosperous state of affairs. The Institute has now made arrangements to occupy quarters jointly with the Mechanical Engineers in the Academy of Medicine building at 12, West Thirty First street, this city, the Mechanical Engineers having bought that house. There it will enjoy large offices, a fine auditorium and ample space for library purposes. The membership now is 427, comprising 2 honorary, 145 members, and 280 associate members. The secretary's balance showed total receipts of $5,846, and a surplus of $64, the actual balance in the treasury, however, being $249. The report of the treasurer confirmed these figures, showing also $350 on hand for building fund.

The chair then appointed Messrs. T. C. Martin, C. G. Curtis and N. Tesla as a nominating committee, to name officers to be elected for 1890-1. Mr. G. Wilkes then read a paper on "Electricity in the Navy," printed elsewhere in this issue.

The nominating committee then reported that they had received a nomination of F. R. Upton as president, but that Mr. Upton absolutely refused to allow the use of his name. They submitted the following "ticket:" For president: Prof. W. A. Anthony; for vice-presidents, Prof. F. B. Crocker, J. Wetzler and F. J. Sprague for managers, H. Ward Leonard, J. C. Chamberlain. H. A. Foster. P. B. Delany; for treasurer, G. M. Phelps; for secretary, R. W. Pope; These were unanimously elected, making the full Council for 1890 as follows; *President*, Prof. W. A. Anthony; *Vice-Presidents*, Edward Weston, Prof. Edward L. Nichols, Prof. F. B. Crocker, J. Wetzler and F. J. Sprague; *Managers*, Charles Cuttriss, George B. Prescott, Jr., Thomas D. Lockwood, William Maver, Jr., Dr. F. Benedict Herzog, Prof. Wm. E. Geyer, H. C. Townsend, H. Ward Leonard, J. C. Chamberlain, H. A. Foster and P. B. Delany; *Treasurer*, George M. Phelps; *Secretary*, Ralph W. Pope. This leaves a vice-presidency and a managership to be filled by council, the vacancies being caused by the death of Major O. E. Michaelis and the resignation of Henry Van Hoevenbergh.

After a discussion on the advisability of having the elections take place wherever the general meeting might be held, and not necessarily, as now, in New York, the meeting adjourned.

The following is a list of members and guests who attended the Boston Sessions of the American Institute of Electrical Engineers, May 21st, 1890.

W. A. Anthony, Manchester, Ct.
G. L. Austen, Boston, Mass.
S. E. Barton, Boston.
R. N. Bayles, New York.
Dr. Louis Bell, New York.
W. H. Blood, Jr., Lynn, Mass.
Geo. W. Blodgett, Auburndale, Mass.
Charles L. Bradley, Yonkers, N. Y.
Edw. C. Caldwell, Boston, Mass.
Geo. F. Curtiss, Lynn, Mass.
John S. Cobb, New York City.
Henry B. Cram, Boston, Mass.
Francis B. Crocker, New York City.
O. T. Crosby, New York.
Chas. R. Cross. Boston, Mass.
A. Floyd Delafield, Noroton, Conn.
A. A. Dion. Moncton, N. B.
A. E. Dolbear, College Hill, Mass.
L. S. Dumoulin, Boston. Mass.
Richard N. Dyer, New York City.
Herbert H. Eustis. Boston, Mass.
M. J. Francisco, Rutland, Vt.
George G. Grower, Ansonia, Conn.
Caryl D. Haskins, Lynn, Mass.
Geo. A. Hamilton, New York City.
Edwin H. Hall, Cambridge, Mass.
Wm. J. Hammer, Newark, N. J.
J. W. Howell, Newark, N. J.
W. L. Hooper, College Hill, Mass.
D. C. Jackson, New York City.
F. E. Jackson, Newark, N. J.
S. Katogi, Japan.
A. A. Knudson, New York, N. Y.
H. Lemp, Jr., Lynn, Mass.
Geo. W. Mansfield, Boston.
Louis B. Marks, Ithaca, N. Y.
J. A. Miller, Providence, R. I.
E. W. Mix, Lynn, Mass.
Edw. L. Nichols, Ithaca, N. Y.
C. Wellman Parks, Troy, N. Y.
F. A. C. Perrine, Trenton, N. J.
Geo. M. Phelps, New York City.

Ralph W. Pope, Elizabeth, N. J.
F. L. Pope, Elizabeth, N. J.
Robert J. Pratt, Greenbush, N. Y.
Geo. B. Prescott, Jr., New York City.
Michael I. Pupin, New York.
E. W. Rice, Jr., Lynn, Mass.
L. H. Rogers, Boston, Mass.
A. L. Rohrer, Lynn, Mass
R. F. Ross, Boston, Mass.
R. W. Ryan, New York City.
W. H. Sawyer, Providence, R. I.
A. C. Shaw.
C. J. Spike, Halifax, N. S.
Kenneth R. Stewart, London, Eng.
O. K. Stuart, Boston, Mass.
John Tregoning, Lynn, Mass.
Elihu Thomson, Swampscott, Mass.
Wm. S. Turner, New York City.
Joseph Wetzler, New York City.
J. P. Wintringham, Brooklyn, N. Y.
Charles Wirt, New York.
Alex. P. Wright, Boston Mass.

The meeting of the Institute was called to order on Wednesday morning in one of the large lecture halls of the Massachusetts Institute of Technology by the Secretary, Mr. R. W. Pope, who introduced Gen. Francis A. Walker, President of the Institute, who, with a few well chosen remarks, welcomed the American Institute of Electrical Engineers to Boston and to the Massachusetts Institute of Technology. He referred to the work which the Institute had been doing in the past and was now engaged in training young men for the profession of electrical engineering, and referred to the fact that the positions already occupied by many of them showed the advantages which a thorough training gives to those who are about to undertake the battle of the world.

The chair was then taken by the retiring President, Professor Elihu Thomson, amid great applause.

DISCUSSION.

Morning Session.—In the discussion of Mr. Fleming's paper on "Electric Lighting in the Tropics," Prof. Elihu Thomson drew attention to the fact that American electrical engineers whose work has been almost entirely confined to temperate climates, have no conception of the effect upon all kinds of electrical apparatus exposed to atmospheric influences in the tropics. He remarked that frequently instances had come under his observation in which well insulated overhead lines in tropical countries had been attacked by the salt spray together with the rotting vegetation, which had entirely destroyed the insulation and converted the copper into a green mass of very little conductivity. It therefore became necessary to take extreme precautions in protecting all exposed work in the best manner possible.

In referring to the results contained in the paper by Mr. L. B. Marks on "Arc Light Carbons," Mr. G. W. Blodgett disagreed with the author and stated, as the result of his experience, that soft carbons were better than hard ones for high tension currents.

Prof. Thomson also referred to the results of a large number of experiments made by him on the subject in determining the best type of carbon to use, and agreed in substance with the results obtained by Mr. Marks. Prof. Thomson pointed out that hissing was mostly met with in carbons having a coarse grain and explained this as due to the vaporization of the positive pole, which becomes so vigorous that the carbon particles explode; but if sufficient time to vaporize is afforded and with small carbon particles this does not take place and no hissing is observed. He instanced an analogy in citing the sublimation of sal ammoniac, which, if carried on slowly, is effected without violent disturbance, but on the contrary may result explosively if carried on too fast. He also cited the case of the Carré carbons, which were of an exceedingly hard nature, but of very uniform composition, and which, while burning, emitted a musical, whistling note due to the uniform explosions which took place. The results of experiments made by Prof. Thomson in 1881 and 1882, seemed to point to the fact that the forced carbon was unsatisfactory at that time, and on examining both kinds the difference in structure pointed out by Mr. Marks was noted; the forced carbon had a glistening aspect from the side and a dull one when looked at from the end, while the molded carbon showed the reverse. His experience had proved to him conclusively that the best form of carbon to-day is the molded carbon, confirming the results of his early experiments. Prof. Thomson pointed out how a long arc blunts the end of the crater and causes the arc to flame and run up the side. This he considered due to the decreased counter electromotive force under those circumstances and he pointed out some of the methods which had been proposed for avoiding the disturbances noted. Among others, he referred to the use of one negative and a series of positive carbons, one arrangement of this kind being due to Dr. Fleming. Prof. Thomson pointed to the special difficulty of making arc lamps of high candle-power, such as are used in arc projectors, operate silently. These lamps give warning when they are going to hiss. This generally consists in the negative carbon sending out striæ of various colors, and in one instance by the use of 150 amperes in an arc having a crater $\frac{9}{16}$ inch in diameter, these striæ were shot out for a distance of eight inches. The introduction of the soft-cored carbons which confined the arc to the centre, Prof. Thomson considered to be a great improvement.

Mr. L. B. Marks referred to the fact that an attempt had been made by him to confine the arc to the centre of the carbon by a magnetic coil, but he had not carried out his experiments to any great extent. Prof. Thomson remarked that he had some time ago also worked in that direction.

Mr. O. T. Crosby drew attention to the fact that the results obtained by Mr. Marks were based on runs of but one hour in each case and suggested that longer runs might have the effect of modifying some of the results obtained. In reply, Prof. Thomson remarked that in his opinion it would be safe to predict the results with accuracy on one hour runs, provided, that the carbons operated upon all came from the same batch; where this was not the case, however, the results obtained might vary. Mr. Marks corroborated the latter statement and showed that one set of carbons obtained by him and subjected to mechanical tests, broke with a strain of 43 pounds, while another required 48 pounds breaking strain.

Prof. Anthony referred to the personal equation in the photometric test in arc lighting and pointed out that due allowance ought to be made for this in estimating illuminating properties of an arc lamp. Mr. Frank L. Pope inquired whether Mr. Marks had determined or taken into consideration, the nature of the raw materials upon which the carbons operated upon by him had been made. In answer, Mr. Marks stated that the companies manufacturing carbons were generally very reticent. One of them, however, he stated, made their carbons of the product of the second distillation of petroleum, to which is added ¼ its weight of pitch; in another case ⅓ its weight of pitch was added.

Prof. Thomson referred to the almost total abandonment of gas retort carbon as a material for arc carbons. He pointed out that it was hard to grind and contained impurities such as iron, ash, etc., which resulted in an unsteady arc, and which it was practically impossible to eliminate. He also remarked that they had completely abandoned the use of forced carbons for high tension arc lamps.

Mr. Frank L. Pope suggested that some one ought to do for the battery carbons what Mr. Marks had done for arc light carbons and subject them to a thorough test in order to determine the relative value of the various types now made. He pointed out that a carbon made of sea weed had shown very good results for battery purposes, and Prof. Thomson remarked that a similar carbon had been submitted to him for arc light purposes, but that its nature was not such as to warrant its adoption for such purposes.

In the discussion of Mr. Parshall's paper on the "Magnetic Data of the Sprague Street Car Motor," Dr. Louis Bell gave the results of some tests made by him on an old type Sprague street car motor, in which he showed that the ratio of magnetic strength of field to armature was as 1 to 1.65, but he pointed out the fact that this ratio was not constant and was liable to vary, particularly when, in consequence of repairs, the motor was taken apart and put together again, owing to the fact that the joints were not so carefully made as when the motor was first put together.

Afternoon Session.—The afternoon session was opened with the new president, Prof. W. A. Anthony in the chair, who thanked the Institute for the honor conferred upon him and expressed the hope that it would continue to prosper under his presidency as it had so signally during that of his predecessor.

The first paper read was that of Mr. Oscar T. Crosby on "The Limitations of Steam and Electric Transportation." In the discussion which followed, Dr. Louis Bell remarked that in the carrying out of long distance high speed railway traffic, nearly all the difficulties met with in street car work disappeared. Principal among these was the avoidance of all gearing by the direct application of the armature to the motor axle and the ease with which the motor could be protected from dirt and dust, etc.

In discussing the paper of Dr. Michael I. Pupin, on "The Practical Aspects of Alternate Current Theory," Mr. Crosby inquired whether in the experience of those practically engaged in such work more difficulty had been met in designing alternating current machines than with the continuous. Prof. Thomson in reply stated that in his experience such was not the case and that the difficulties met with in the one case were, as a rule, absent in the other, so that it might be said that no greater difficulties are met with in the alternating current machines than in those designed for continuous current. Further discussion of this paper was postponed for lack of time.

After reading his paper on "Automatic Electric Welding Machines," Mr. Hermann Lemp, Jr., gave an experimental demonstration with the machines which had been placed on the platform. Welds between various metals were made, the time consumed in each being but a small fraction of a minute and the tests of the welds showed them to be perfect. There was also shown an ingenious device for stripping the wire of the burr made by the weld, so that the diameter was reduced to the same as that of the original wire and leaving the surface smooth for a continuous winding. Several of the members present, after witnessing the operation, were able to make perfect welds, owing to the remarkable simplicity and automatic qualities of the machine.

Between the morning and afternoon sessions a group picture of the members of the Institute was taken on the steps of the Brunswick House opposite the Institute. Invitations were read by the Secretary from the Boston Society of Civil Engineers inviting the members to inspect various points of interest about the city. The Union Car Company also invited the members to an inspection of their storage car road operating between Beverly and Danvers. On Thursday morning the members of the Institute assembled at the Massachusetts Institute of Technology at nine o'clock and inspected the electrical and physical laboratories, all of which were thrown open. The facilities offered for thorough work in the electrical laboratories especially were evident. A complete electrical plant, embracing various types of dynamos, both continuous and alternating, motors, converters, etc., is provided, together with a complete installation of measuring instruments for testing, together with a photometric room.

After devoting an hour to the laboratories, the members entered carriages which had been provided by the West End Railway Co., of Boston, and were driven to the large power station now in course of erection. The work has thus far progressed only to the erection of the foundations, which alone are well worthy of a visit. The station is designed for 18,000 horse-power and must undoubtedly be considered one of the finest engineering enterprises undertaken in this country. The present temporary station, equipped for 1,500 horse-power, is itself a model in its way, and thorough arrangements for controlling and supervising circuits and apparatus are everywhere manifest. The members were conducted about by Mr. Dumoulin, the assistant engineer of the company, and Mr. Pearson, the chief engineer of the company. Numerous detail drawings which were explained to the members showed the plan which it is proposed to carry out in the construction of the station. The mechanical engineer in charge of construction is Mr. C. Hirt. From this point the members again entered carriages and were driven to Park Square, where a number of special cars in waiting took them over the Chestnut Hill Branch of the Boston electric railway system. This branch, covering a distance of between four and five miles, ends at the Chestnut Hill Reservoir and passes through one of the most fashionable suburbs of Boston. The road is everywhere built with the greatest care and for the largest part of the way runs in the centre of a magnificent boulevard. For a large part of the way the tracks run through a green sward, so that at a distance the rails are almost completely hidden from view. The quality of the work which has been done here can best be estimated by the fact that the speed on this part of the road, being outside of the city limits, frequently reaches 15 and 18 miles an hour. The road has been largely instrumental in building up this suburb, and the large number of houses noticed in the course of erection gives unmistakable evidence of the value which electric railroads add to suburban property. Upon the return of the members they were entertained at luncheon by the West End Company at the Parker House, where a vote of thanks was unanimously carried.

At two o'clock the members started on the journey to Lynn as the guests of the Thomson-Houston Company. On their arrival they were conveyed to the factories of the company and started on a tour of inspection of the shops in squads under the leadership of guides provided for that purpose. It would take many columns to describe the variety and interesting character of the work being carried on here, and we must content ourselves with merely stating that hardly a nook or cranny was left unvisited by the visitors. While the various processes of dynamo, motor and lamp construction were greatly admired and enjoyed by the visitors, the operations going on in the welding factory elicited unbounded enthusiasm. In order to show the visitors a large variety of work and the ease with which it could be accomplished, machines welding metals from the smallest sized wire to bars an inch and a half in diameter, pipes, steel cables, etc., were exhibited to them. As one of the members upon leaving remarked to Prof. Thomson (who accompanied the party throughout the day), the visit to the factories was a liberal education in itself. Considerable interest was also shown in the new wattmeter of Prof. Thomson, which is designed to operate equally well on both continuous and alternating circuits. After a thorough inspection, the members departed, with cheers for Prof. Thomson and the Thomson-Houston Company.

The Boston meeting will long be remembered as one of the most interesting which has thus far been held by the Institute, and the success attained was largely due to the untiring efforts and courtesy of the members of the Boston Electric Club, the West End Railroad and the Thomson-Houston Electric Company, whose only aim seemed to be to make the visiting members thoroughly at home, in which effort they may be said to have succeeded in the most eminent degree.

THE RELATION BETWEEN FIRE INSURANCE AND ELECTRIC INTERESTS FROM THE UNDERWRITERS' STANDPOINT.[1]

BY S. E. BARTON.

At the annual meeting of the National Board of Fire Underwriters in New York on the 8th of this month, several very interesting papers upon important topics affecting the welfare or ill-fare of the business were presented.

An extract from the newspaper reports of that meeting reads as follows: "The most interesting report came from the committee on lighting and heating, read by Chairman John H. Washburn. 'The great problem before us to-day,' he said, 'is the management of the various systems of electric lighting, which is not the harmless thing we had imagined, but a most prolific source of danger. It has come to stay, however, and in time it will probably be as safe as any light in use.' With the report a graphic diagram was handed in, which showed that while electric wires and lights were responsible for losses of only $480,000 in 1886, the value of property injured by fire which could be traced to the same source in 1889 was $5,533,000."

Such a report coming from a body representing, as its name implies, the fire underwriters of the nation, conveys to the public the idea that "the relation between fire insurance and electric interests from the underwriters' standpoint" is a very gloomy one for the former.

I was sorry to see such a bald statement go forth without any explanation as to how it was arrived at, or what it indicated. If it was intended to indicate, as it certainly does to every person not acquainted with the facts, that the danger of fire from electrical causes had grown to be twelve times greater in 1889 than it was in 1886, it is shamefully unfair, because it is untrue.

As the figures given are identical with those contained in the "Chronicle Fire Tables," published by the Chronicle Company of New York, I presume they came from that publication, and therefore it is fair for me to draw from the same source to show how unfair the report really is.

Those tables show that in 1886 there were 29 fires from "electric wires and lights," causing a loss of $450,000; in 1887, 66 fires and $881,000 loss; in 1888, 91 fires with $1,587,000 loss; and in 1889, 74 fires with $5,533,000 loss. The yearly increase in the *number* of fires reported is nowhere near the percentage of increase in the use of electric lights and wires, and therefore the number of fires was not used to show the comparative hazard by years. It looked much more startling to use the amount of loss, and for that reason I presume it was used; I can see no other reason for using it. But where did the great increase in amount of loss come from? Why! from the Boston fire of last Thanksgiving day, which "everybody says was caused by the electric wires," but which *nobody* has proved. The fire marshal in his investigation exhausted his energies and all means at his disposal, and certainly the bulk of the testimony taken would naturally lean towards fixing it upon the electric wires. The Massachusetts Insurance Commissioner, in his 1889 report, just issued, says "the preponderance of the testimony seems in favor of the theory that it was caused by the electric wires;" therefore, in his opinion (which is good enough for me), it is a "theory" that confronts us and not a condition nor a fact. That loss amounted to about three millions and a half. It was injected into the destruction account of "electric wires and lights," making the account four times as large as in 1888, and yet, admitting the right to charge the fire to that account at all, it only increased the number of accidents by one. Supposing the fire had got still further beyond the control of the firemen, and had destroyed one hundred millions instead of three and a half, of course it would have proved (according to the logic of the report of the National Board) that electricity is twenty-two times as hazardous as the report makes it out to be.

The official return of the big fire at Lynn says it was caused "by a draft from an open door blowing the blaze from an oil stove down around the burner, causing the stove to explode." The loss by that fire was about four and one-half millions, and I presume it should be charged in equal proportion to open doors, drafts and oil stoves.

Two fires were reported in Massachusetts last year as caused by "reflected rays of the sun." If they had destroyed five and a half millions of property the combination of the sun and a reflecting surface might fairly be regarded as "a most prolific source of danger."

In the language of the report which I have referred to I am compelled to say that the committee that made it "is not the harmless thing we had imagined, but a most prolific source of" misrepresentation. Let me bore you with a few figures from the Massachusetts insurance report referred to, as to the causes of fires. They are the official returns from all the towns in the state, and cover the period of 1884 to 1889, inclusive.

---

[1] A paper read at the dinner given by the Boston Electric Club to the American Institute of Electrical Engineers, May 21, 1890.

Broken and exploded kerosene oil lamps and lanterns:—	
Number of fires in 1884	136
Number of fires in 1889	217
Increase of 1889 over 1884, 59⅛ per cent.	
Explosions of gas:—	
Number of fires in 1884	4
Number of fires in 1889	8
Increase of 1889 over 1884, 100 per cent.	
Careless use of matches:—	
Number of fires in 1884	45
Number of fires in 1889	90
Increase of 1889 over 1884, 100 per cent.	
Children playing with matches:—	
Number of fires in 1884	78
Number of fires in 1889	116
Increase of 1889 over 1884, 49 per cent.	
Ignition of curtains and goods by gas and candles:—	
Number of fires in 1884	42
Number of fires in 1889	38
Decrease in 1889 from 1884, 10 per cent.:	

and this decrease is doubtless due to the fact that the incandescent lamp is rapidly replacing the gas jet and candle in windows and stores.

In 1884 "electric wires" caused 6 fires, and in 1889, 7; increase of 1889 over 1884, 16 per cent.

Total number of fires for the whole six years from each cause is as follows:

Broken and exploded lamps and lanterns	947
Explosions of gas	28
Ignition of curtains and goods by gas and candles	233
Careless use of matches	447
Children playing with matches	473
Electric wires	42

Besides these, during the same period, 25 fires came from gas and candles near wood-work, and 1884, 1885 and 1887 are not included, as they were not reported.

Lightning caused 208 fires; plumbers' pots, 27; thawing water pipes, 89; tramps, 54. There appear to be none charged to the much despised "tramp wire," unless he was the means of conducting the subtle fluid in some of the 42 cases against electric wires.

Cigar stubs in wooden spittoons caused 41 (1884 and 1885 not reported).

Smoking caused 233 fires, to say nothing of the 3,024 marked as "unknown," many of which were doubtless due to this "most prolific cause;" and yet "the management of the various systems" of smoking is not regarded as "the great problem" before the fire underwriter of to-day. He smokes day in and day out, perhaps causing his own share of fires, and yet he looks with increasing alarm upon a system of distributing light and power for the benefit of mankind, that has only been charged with causing 42 fires in Massachusetts in five years, as against 233 from smoking.

Let me step outside the confines of my little native state and give you a few comparative figures for the whole country, taken from the Chronicle Fire Tables for the year 1888. (I have used 1888 instead of 1889 because I happened to have them more handy.) I have selected a few classes of risks in which electric lights and wires are probably more generally used than in others.

In clothing stores the whole number of fires reported is, for the year, 1,072, 28 of which came from gas jets, 21 from lamps exploding, 9 from lamp accidents, 3 from gas explosions, 13 from matches—in all 74, as against 6 from electric lights and 9 from electric wires.

In country and general merchandise stores 4,847 fires are reported, of which 39 came from lamp explosions, 8 from lamp accidents, 3 from gas jets, 20 from matches—in all 70, as against 1 from electric wires.

In crockery and glassware stores 179 fires are reported, of which 8 came from lamp explosions, 7 from lamp accidents, 3 from gas jets, 4 from matches—in all 22, as against 1 from electric wires.

In dry goods stores 1,858 fires are reported, 123 of which came from gas jets, 34 from lamp explosions, 6 from lamp accidents, 7 from gas explosions, 19 from matches—in all 197, as against 10 from electric wires and 3 from electric lights.

In fancy goods stores 519 fires are reported, 28 of which came from lamp explosions, 7 from lamp accidents, 27 from gas jets, 9 from matches, 2 from candles—in all 73, as against 4 from electric wires.

In the United States in 1888 the whole number of fires from the above named causes is reported as follows: Lamp and lantern explosions, 528; lamp and lantern accidents, 190; gas jets, 179; gas explosions, 63; matches, 592—in all 1,552, as against 49 from electric lights and wires.

There were 53 from stationary engines and boilers, and that number, though small, can be reduced just as fast as the electric motor takes the place of the boiler and stationary engine.

In the matter of insurance upon electric generating stations, the "great problem" is practically settled; and it has been settled by the establishment of an Electric Mutual Insurance Company, organized for the prime purpose of improving and insuring such risks. There is no trouble whatever to-day in procuring ample insurance in the strongest of stock or mutual companies, provided the Electric Mutual carries a part of the risk; and I predict that within one year companies that have heretofore frowned upon an offer of insurance upon the best of such risks, or have charged excessive rates, will be competing for the business. The one truth contained in the extract of the National Board report, namely, that the "business has come to stay," together with the fact that the owners of stations are willing to take their own risks by insuring in a company of their own, has inspired many of the underwriters with courage who were previously possessed of fear and doubts.

Of the 31 fires that were reported in electric light stations in 1888, 11 were from exposure to other risks, 4 were from unknown causes, 5 were from causes not reported, 1 each from engine, furnace, spontaneous combustion, lightning and explosion, while 6 came from "electric wires;" showing that after all it is not the mysterious electric current nor the pranky wire that are responsible for the havoc, but that the ordinary causes that pertain to other risks, such as improper location, contiguous to bad neighbors, and carelessness of various kinds, are the chief sources of danger.

In seven years previous to and including 1888, 80 fires are reported in electric light stations, about 11 per year on the average.

On the whole, I don't know what the relation between the interests is, from the underwriter's standpoint. What are his views to-day may not be to-morrow. There is no hazard that underwriters, as a rule, have made so little effort to understand, and consequently they are too largely guided by the caprice of popular prejudices and beliefs, neglecting to carefully study their tables of experience and be guided by the logic of events. There is also no hazard around which they have ever thrown so many restrictions. Those of us who know what peculiar and improbable conditions must exist in order for the "electric wires" to cause fire, can only look on and hope. Enlightenment comes slowly but surely, and the day is not far distant when the large majority of fire underwriters, forgetting their present ideas, will say "I always maintained it was the safest kind of light and power." In the meantime the present rapid development will go on regardless of the underwriter's standpoint. A few years ago his favor or opposition meant easy or slow progress for the electrical pioneer, because the first question asked was, "how will your wires and lights affect my insurance?" But the business has "come to stay," and that question is less frequently asked.

The same difference however exists to-day that always did exist between good and poor installation, and therefore it should be the aim of the electrical men to seek the co-operation of the underwriters in securing the observance of safe fundamental rules.

ELECTRIC LIGHTING BY GAS COMPANIES.

The following table is a summary of the list of gas companies operating electric lights given in "Brown's Gas Directory for 1890." Compared with the figures of a year ago the showing is:

SYSTEM.	ARC.	INC.
Thomson-Houston	16,927	45,055
Brush	6,090	4,259
Westinghouse	321	49,967
Edison	....	13,858
American	1,537	175
United States	632	6,141
Schuyler	1,066	....
Ball	962	6
Western Electric	788	....
Fort Wayne	1,756	8,005
Van Depoele	450	....
Waterhouse	287	....

ELECTRIC LIGHTING IN THE TROPICS.[1]

BY WILFRID H. FLEMING.

ONE of the chief difficulties that an engineer experiences who is called upon to install a plant of any considerable size in tropical countries is the trouble of procuring any kind of skilled labor for this particular class of work. Another difficulty is that he is so far from his base of operations—the factory—which will often lead him to depend upon himself in overcoming obstacles that arise from time to time as the work progresses. Language and the heat, as well as fevers, are minor affairs.

Electric lighting has already gained many warm adherents both in the East and West Indies, more especially in the former where plants of considerable capacity have been in active operation for the past eight years. It is especially adapted for use in houses in warm climates, such as that of India, where the old-fashioned "punkah" is in daily and nightly use for cooling the rooms, accompanied with its attendant noise as the "punkah wallah," a servant, pulls it backward and forward causing the continual flickering of the lamps or gas. That system will, in time, I hope, give place to the noiseless motor fans and steady incandescents, thus enabling the Anglo-Indian to read and rest in comfort.

A central station plant that the writer was engaged upon lately in one of the chief cities of the West Indies, would compare favorably in size and equipment with one situated in a city of a corresponding number of inhabitants in the United States. Alternating current dynamo of a capacity of 4,500 16 c. p. lamps were employed for lighting the chief stores, theatres and private houses, and 600 arc lights of 1,200 c. p. each lighted up the main streets and parks.

It was at first intended to run a small plant in connection with the existing gas works, more as an experiment than with a view to actual financial success, but in the space of six months the station was more than trebled from its original capacity.

The people took to it from the start, paying cheerfully the prices that were demanded To an indolent race it was a great boon. Money to them, it would appear, was of less account than the trouble and work called upon to go around and light up the different oil and gas lamps, since all the lights were switched on the different circuits at sunset. In the tropics, as is well known, there is no twilight. Darkness comes on within 10 minutes of sundown and the whole plant practically goes into operation at once.

The construction work on this particular plant was necessarily somewhat slow, as men unaccustomed to erect a 30 or 45-foot pole took their time to do so, in which operation they received the appreciation of the usual army of idlers. Poles suitable for carrying a number of circuits had to be imported from the United States, as well as the ornamental wooden columns for supporting the lamps in the parks and public squares. Poles of native growth could not be found straight enough and, even if of sufficient length, were weak. Some poles could have been had from a tree called the iron wood tree. This wood, however, is of so close a grain and so very heavy that it was out of the question to use it. Many of the business streets were not more than from 20 to 30 feet across, including the sidewalks. Moreover, as curtains or awnings are stretched overhead from side to side by the owners of the stores to shelter and protect their goods from the sun's rays, it was impossible to erect a pole line down these streets, I found it better to run a two-inch iron piping up the side of the houses every 150 feet to a point 6 feet above the coping stone, and then attach to the top of this pipe a T, inserting in this T wooden cross arms to which the insulators were attached in the usual manner. It must be borne in mind that the houses are not of very great height. Where this arrangement was impracticable owing to the varying heights of the houses, I inserted strong iron brackets in the buildings set in with cement and well painted with rust-proof paint.

In India considerable care has to be exercised in putting up a pole line. If you want your work to stand any length of time, the base of the poles for one sixth of their length must be thoroughly well creosoted to resist as far as possible the ravages of an insect called the white ant or "termite." These insects live on wood. They attack even the wood-work of the houses and soon reduce the thickest timber to a mere shell. They live in trees and construct nests of great size like small sugar casks made of particles of gnawed wood and cemented by a kind of gluten. They are so strongly attached to the branches that they cannot be shaken down even by violent storms. It is a good plan to paint the poles eight feet above the surface of the ground with good gas tar if obtainable. In these climates special attention should be given to protecting the working parts of arc lamps, owing to the fact that rain occurs only for about three months of the year, and to make up for this loss the humidity of the atmosphere is remarkable. It is not at all infrequent to find early in the morning the bottom carbon holders full of water, unless provision is made for draining this off. During the hot season, a breeze springs up between 9 and 10 o'clock in the morning, and the ground being dry, the dust is terrific. Insects of a large size—much more so than those found in the northern climates—bats and small birds attracted by the glare are found either in the globes or lying at the base of the lamp posts in large quantities every morning; and the wholesale slaughter that takes place nightly seems to have no effect in diminishing these pests.

It was found better, therefore, on the arc service to give a man about 25 lamps to trim and clean per day, and the native entrusted with this work was held responsible, and if the lamps were found in a dirty condition he was fined, which usually had a good effect.

In the construction of station buildings one is guided much by the facilities for procuring stone, brick or other suitable material in that particular locality. Galvanized iron is sometimes used for roofing, but more frequently roofs are constructed of a sun-baked clay tile, provision being made as is usual for an ordinary wire tower for distributing the various circuits. A point to be noted is that the engineer should construct his rain gutters for taking off the storm water at least double the size that is ordinarily allowed for temperate climates. Roofs and the outsides of the buildings are white-washed.

To give an idea of the heat from the sun, I may mention that I had to replace considerable quantities of insulated wire after it had been up only a short time, the insulation in places sagging right away from the copper wire and finally dropping off. During the rainy season prevailing in the West Indies in the months of June, July and August, and in the East Indies, known by the name of the southwest monsoon, and prevailing from May to the latter part of August, electrical storms occur almost daily. They are often exceptional in violence, and much trouble and anxiety arises from possible damage to line, lamps and dynamos, even though provided by good lightning arresters.

While a heavy storm was in progress one night last summer in the West Indies, I noticed when in the station a curious effect of a flash that fused the lead strips on an ordinary saw-tooth arrester connected with one of the incandescent circuits. The strips were entirely destroyed or volatilized and what was before a polished plate of brass was now tarnished with a film of the lead vapor, and there was distinctly marked, as if photographed on the plate, a zig-zag streak, in all appearance like a photograph that had been taken of lightning. Engineers, during the prevailing season of storms, should take particular pains that their lines and machines are thoroughly well protected and that the arresters have good earth connections.

A sad case came under my notice that happened at a temporary installation for illuminating a camp in Poonah, in the Bombay Presidency, with arc lamps, in honor of a visit of an influential Rajah. Whilst the festivities were taking place in the evening, a heavy storm occurred. Lightning entered on the line, no provision had been made for diverting its course, and it destroyed the dynamo besides killing the native oiler who just at that moment was engaged in filling up the oil cups on the bearings. He was either thrown or fell across the commutator end of the dynamo, as he was found in that position, his hands much burnt, as well as his feet.

In the year 1877 the first commercial arc lamp was in use at the offices of the Bombay *Times*, and if I remember correctly it was the first light shown in the Indian Empire. From that date on, the demand for lighting has been on the increase; but pretty nearly all the work has been confined to isolated work and small central stations, cotton mills, sugar and indigo plantations, government buildings and large private dwelling houses. Places of business and offices do not require lighting, as business is conducted by the merchants only from 7 o'clock in the morning till 4 in the afternoon. The inhabitants of hot climates necessarily spend much of their time out of doors and are fond of social gaiety. They have been famous for centuries for skill in illuminating, and this fact has added much to the popularity of arc and incandescent lamps, which as is well known, particularly lend themselves to artistic illuminating purposes. From this knowledge, in the early part of the year 1885, I imagined that it would be a financial success to get together a travelling portable electric light plant, consisting of a vertical boiler, engine and two dynamos, one an 8 arc light machine and the other a 100 light incandescent, both mounted on a stout frame which rested on a pair of bisel trucks. This work was carried out, and I was kept actively employed for many months in going round to different large Indian estates and native palaces for the fetes that attend the various religious and family ceremonies that the wealthy natives are fond of indulging in. Large sums of money are spent and the festivities often last for a week or longer. It turned out to be as I surmised it would, a regular "bonanza," until on one occasion in bringing the unwieldy contrivance down a steep hill on one side of which was a ravine, it fell over; and it is needless to relate that the whole apparatus was seriously damaged. I found it would not pay to patch it up again, so, after stripping everything that was portable I left the remainder to lie and rust in the tropical vegetation.

Owing to the high price of coal, which is a costly article in the tropics, ranging from $8 to $50 per ton delivered, it is well to employ the most efficient and economical engine for motive power, more especially for central station work. In the station previously referred to, we were running with high speed compound condensing engines with satisfactory results.

---

[1] A paper read before the General Meeting of the American Institute of Electrical Engineers, Boston, Mass., May 21st, 1890.

In many sugar plantations in the West Indies where the installations are of a comparatively small size, economy in this direction is not practiced as the amount of steam used is not missed, the boiler capacity on estates ranging from 100 H. P. to one at Cienfuegos, Cuba, of 2,500 H. P. It behooves the engineer, however, who has charge of a plant to exercise considerable care and watchfulness over his native firemen. The natives, as a rule, I have found, if treated with kindness and forbearance, show an aptitude in learning and taking hold that is often remarkable, more so than with some of their brethren of a lighter color who, because they have been taught how to start and stop a dynamo or trim an arc lamp, give themselves all the airs of an expert in electrical matters, and have got beyond that stage when they are willing to be instructed or to be obedient to orders, an unwillingness that sometimes leads to disastrous results.

The types of machines chiefly in use in the East Indies are those of English and French manufacturers, Siemens, Gramme, Silvertown and other well-known types. Those in use in the West Indies and South and Central America are generally of American make, and the market is not a small one. The great strides that both the foreign and home companies have made in the last two or three years in the supply and equipment of electrical plants for these distant lands are very evident signs that this particular business is receiving great attention at the hands of local merchants, planters and city or town officials and that they are more and more influenced by the many advantages to be gained by the use of electric lighting. Planters find now that it is much to their gain in a financial way. In former years, for example, the facilities of shipping their produce were restricted, and the work was done in daylight, and slowly. Now with weekly and almost daily sailings, it is an absolute necessity that they should get their produce ready with the quickest despatch possible, and this they do with the aid of the electric light. When an engineer is called upon to install or take charge of an electric light plant, it will be well for him to insist pretty closely not only that all the materials specified in the estimates have been shipped, but that every class of tool requisite for constructional work is included. Much time is lost and much trouble is made when you find that your outfit does not include "climbing spurs" or draw vises and other important articles. I have known engineers who have had expensive testing sets, Wheatstone bridges, reflecting galvanometers and other delicate instruments sent out with them, and then found that they had few or any tools to work with, and that the nearest hardware store was many miles away through a rough country, and even then the store, when reached, did not contain the requisite goods, there having been no stock kept because there was no demand made for them. Spare armatures, complete sets of arc lamp apparatus as well as duplicate parts of dynamos, spare brasses and gear for engines and tubes for boilers should always be included and it should be seen that they are shipped.

Apart from the vicissitudes incidental to life in the tropics, there is, I think, always a satisfaction and pleasure in the successful completion of an installation, knowing as one does that it is a potent factor in the greater civilization of those countries, demonstrating to the inhabitants, who have heretofore depended on artificial illumination of the same primitive character and manner as their forefathers used through ages past, what science, aided by her lieutenants, "pluck and energy," can accomplish.

THE INDUSTRIAL UTILIZATION OF THE COUNTER-ELECTROMOTIVE FORCE OF SELF INDUCTION.[1]

BY THOMAS D. LOCKWOOD.

It may as well be confessed at the outset that although my production has cost me considerable thought, it does not claim to advance any original ideas. Its claims to attention are based solely upon its merits as a chronicle. There seems to be among the modern race of electricans not a few who regard that species of counter-electromotive force which is the subject of this paper, as being the only species in the genus. While of course this view is erroneous, it is easily accounted for by the notorious fact that the American electrician as a class has little time to study. The fact, however, while it is indeed as I have termed it, "notorious," is still to be deplored; for it is certain that were electricans fully informed not only of the researches which took place before their own, together with the results of the said researches, whether these results took the form of success or failure, there would be much less valuable time wasted in supposed original research; there would be far fewer valueless inventions produced; and there would be a much smaller amount of subsequent vexations and useless litigation.

While counter-electromotive force, generally speaking, is a genus, the counter-electromotive force of self-induction is a species, and while an illustration of this statement will no doubt to most of us be an operation something in the nature of carrying coals to Newcastle, or water to the Mississippi valley, I cannot believe that it will be a waste of time, since doubtless we have many members who have not fully considered the subject.

Consider for a moment a definition of electromotive force. What shall we say it is? It certainly is not a natural force like gravitation, and I do not think we can do better than concede that we call it a force, simply because it is convenient so to do; and define it as any agency tending to set up that form of motion or vibration which we call electricity; or, if you please, any agency tending to the manifestation of electricity.

We are constantly hearing that a current of electricity is the result of a difference of potential between two points connected by a conductor; but though this statement through constant repetition has come to be as it were "human nature's daily food," I am inclined to consider it as being after all but a mathematical way of saying that a current of electricity is the necessary result of an electromotive force provided with a closed conducting circuit. For it is the electromotive force which first determines the difference of potential, which therefore may be considered as being a kind of initial result. Following out this train of thought, it appears then that electromotive force is a function of the source or instrumentality which develops the current, and expresses the totality of difference of potential in the entire circuit; and while we may properly speak of the difference of potential, or fall of potential between any two points on the circuit, I think we can not with equal propriety speak of the E. M. F. in any other way than as something pertaining to the source.

And further consideration of the same idea, shows the incorrectness of the popular phrase often used of late years, even by many eminent and able electricians, "a *current* of so many *volts*," the electromotive force being in no sense, near or remote, an attribute of the current.

To run counter to anything, is to run against it, to run in opposition to, to act opposedly; and so a "counter-electromotive force" may be defined as any agency tending to develop a current of electricity in a circuit, opposite in direction to that of the current excited therein by the initial electromotive force.

A familiar instance is that of connecting up in an electric circuit a certain number of cells in opposition to a number of other cells. This constitutes a primary counter-electromotive force and its inclusion in the circuit reduces the current in two ways; first by reducing the acting electromotive force to a value equal only to the algebraic sum of two opposing forces; and secondly, by adding internal resistance of the value of the cells added in opposition.

Another familiar illustration is found in that ingenious class of dynamo regulator, which acts by causing the opposing brushes to creep around the commutator and, according to the work which is being done in the external circuit, to include in the circuit (by increasing or decreasing the lead of the brushes) a greater or less number of armature coil sections exerting an electromotive force in opposition to the electromotive force which is developing the working current.

In these cases a utilization is made of counter-electromotive forces deliberately organized for the purpose, but they are not counter-electromotive forces due to self-induction.

At a very early period in the history of voltaic electricity it was discovered that there was some deteriorating force at work in every voltaic battery which depreciated the current to a much greater extent than exhaustion of the liquids or consumption of the solid elements could account for; and in 1801, Gautherot found[2] in this phenomenon which has foolishly been called "polarization," the germ of the secondary cell. He discovered that wires of platinum or of silver which had been used to decompose salt water acquired a power of themselves yielding a current when placed in acidulated water, and could cause muscular contractions of a frog's leg and produce the galvanic test. And subsequently it was ascertained that the operation of a voltaic battery tended to coat the negative plate with hydrogen which tended to set up a counter-electromotive force between the hydrogen and the surface of said plate, which thus reduced the available energy of the battery, and that this action could be transferred to the electrodes of the same battery if placed in a separate decomposing cell, and there tended to form electrically opposed surfaces which could themselves be used to develop a current in a direction opposite to that of the original current. As we all know, this operation, long regarded only as an unmitigated evil, is now utilized in the formation and operation of cells adapted for the electrical storage of energy.

The counter-electromotive force of self-induction distinct from the foregoing, is that discovered by Professor Henry; and its most important use is that which has been mainly brought out in association with the employment of alternating or other currents for the purpose of regulation. By reason of the fact that *this* utilization has proved to be overwhelmingly important, the electrical fraternity has partially lost sight of many earlier and contemporary instances of the useful employment of self-inductive electromotive force; which is indeed a close analogue in its character, mode of generation, and capabilities of use in regulation, to that developed and utilized in the operation of electro-motors.

---

[1] A paper read before the General Meeting of the American Institute of Electrical Engineers, Boston, Mass., May 21st, 1890.

[2] See Izarn's Manuel du Galvanisme, Paris, 1804, and Phil. Mag., 1806, Vol. xxiv., p. 185.

First—I desire to point out that though Henry was the first to study and discuss self-induction, he was not the first to notice its effects.

Until quite recently I, together with nearly everyone else, had supposed that the earliest published notice of this phenomenon was Henry's account[3] of his observation, published in 1832; but I have in my researches on the subject, dug out the fact that this is not so. I find that an experimentalist, Vassali-Eandi by name, records that[4] with a pile of fifty pairs he found that the fluid passed along a copper wire plated with silver, 1,151 feet in length, in a time incommensurable; the shock in this case was three times as strong as that experienced by immediately touching the two extremities of the pile.

The above isolated statement of facts stands as I believe alone, and there is no record that it led to further research.

Henry on the contrary perseveringly pursued, and made himself master of the subject; and the record of his original observation, brief though it is, details the appearance of a vivid spark on the breaking of a battery circuit, if a wire thirty or forty feet in length be included in that circuit; he shows that the effect is increased by coiling the insulated wire into a helix; and that the effect depends in some measure on the length and thickness of the wire. The note concludes with these remarkable words: "I can account for these phenomena only by supposing the long wire to become charged with electricity which by its reaction on itself projects a spark when the connection is broken."

This, though brief, is then the first analytical notice of the electromotive force of self induction, so long erroneously denominated after its result, the "extra current."

It is unfortunate that Prof. Henry did not for some time pursue the subject, and we do not hear from him again until March, 1835.

Meanwhile his great contemporary, Faraday, had taken it up pursuant to an observation of one William Jenkin, and showed self-induction to be a corollary of his former masterly experimental researches in magneto-electro induction.

Faraday notes[5] the following points: Self-induction exists in simple helices as well as in electro-magnets, though not to the same degree.

Helices are superior in developing induction to straight wires, and long wires to short ones.

Self-induction practically disappears when the conductor is permitted to inductively act upon a neighboring closed circuit.

The amount of self-induction depends upon the length of wire exposed to inductive action.

An iron core within helices, much exalts the action of self-induction.

The self-inductive effect depends not "upon a permanent state of the core, but on a change of state."

Henry now again takes up the matter and in a consecutive series of papers, practically runs it to earth.

[6] In a paper of March, 1835, he gives more in detail some of the conditions of the development of self-induction. A long wire is better than a short one; a helix better than a straight wire of equal length. He also describes a shocking coil, and also a deflagration coil of but one wire in which self-induction is involved.

[7] A little later he elucidates the origin and properties of self induction and records that some additional energy appeared when iron was used as a core, but not much, because his coils were flat and not elongated helices. He ascribes all of these effects to dynamical induction, and shows that in a coil of a number of convolutions the convolutions act inductively on each other, and inferentially that the energy of the self-induction is the sum of that of the different coils.

[8] In a third paper further experiments in self-induction or with the extra current, as it was then called, are discussed. We learn that the electromotive force of any self-induction coil within certain limits is dependent upon the length of the coil.

That the form of the coil has considerable influence on the intensity of the action. In the experiments of Dr. Faraday, a long cylindrical coil of thick copper wire inclosing a rod of soft iron was used.

This form produces the greatest effect when magnetic reaction is employed.

The "extra current" of self-induction developed in a coil, is controllable by the presence of an immediately adjacent independent coil. It is energetic when the circuit of the adjacent coil is open but absent when the adjacent circuit is closed."

Of course it is impossible in this paper even to indicate the many good things which are spread before the reader of the researches of both Faraday and Henry. They are well worth study, and in fact they laid a solid foundation for the work which is being done now.

Both discovery and invention are displayed in their work, much of which has only found its sphere of action within the last four years; for it is emphatically true as has been said by Mr. W. H. Preece, "that though we are accustomed to hear that necessity is the mother of invention, the child is as a matter of fact often born before its parent.

As is frequently the case with electrical discovery, self-induction was long recognized, that is for the most part and by the generality of electricians, only as an unwelcome guest whose parting was to be speeded.

It was manifested mainly by an undesirable spark appearing upon the break of electric circuits in telegraphic, scientific and medical apparatus, and tending to burn away or oxidize contact points; while in the case of the two wire induction coils its effect was to reduce the spark passing between the terminals of the secondary; and many have been the expedients, wise and otherwise, which were devised for its banishment. Many of these were patented; more were not, inasmuch as the fever for patenting everything from a solar system to a thought had not then come into fashion.

Examples of this class of expedient are, respectively:

British Patent, No. 12,772, September 20, 1849, granted to those old heroes of electric lighting history, Staite and Petrie, which has for its 18th clause, a mode of "preventing the spark when breaking contact in galvanic circuits. A thin platinum wire may still convey some portion of the current after the main circuit is broken, or a series of sufficiently long conductors may break contact one after the other." The preferred way, in plain English, was to connect a fine wire as a shunt round the break, and thus to furnish a closed circuit in which the self-induction circulated its current of breaking.

United States Patent, No. 33,269, granted to J. E. Smith, September 10, 1861, for a means of preventing the spark between the local points of a relay on breaking the circuit; shunting the break by a wire having two terminals dipping into a bottle of water.

Moreover, as is well known in the ordinary induction coil, the action is emphasized by shunting the primary break by a condenser as first suggested by Fizeau.[9]

This, as I shall point out later, is a real instance of the industrial utilization of self-induction.

Other early investigators in this line reduced the spark of breaking the circuit, by wire shunts also.

Although, as I have stated, the recognitions of self-induction were mostly recognitions of an adversary, there were one or two early instances where the enemy was subjugated, and made to expend his energy usefully. The most notable instances of this are the single wire spark coils of Page and Callan[10] which were made especially with a view to exalt the self-inductive effects, and with which metals were fused and electrolytes were decomposed.

These were the forerunners of the spark coils used at the present day in electric gas lighting and comprising a single long coil wound to a suitable length upon a long core of iron wires.

There can, however, be no doubt that the principal attempts to make useful the counter-electromotive force of self-induction, and likewise the principal successes achieved, have been in the line of controlling, regulating or modifying the original, initiatory, or primary currents from which they have been developed.

I have compared this to the transposition of a given number of battery cells.

This analogy is however imperfect, since in cells of battery we may for the sake of argument regard the E. M. F. as being practically constant. Certainly they will in no sense regulate themselves in accordance with conditions automatically, but the inductive resistance *will* do this. For it is dependent for its efficiency as a generator upon the strength of current flowing through it. Therefore, if the current through it, due to the impressed electromotive force, from any reason falls, the counter-electromotive force will also diminish and thus will permit a greater amount of the initial force to act; or, in other words, will permit the impressed energy to become more effective. Suppose we have in the main circuit of an alternating dynamo, supplying a number of incandescent lamps in bridges uniting its mains, an adjustable resistance; and suppose the inductive resistance, which we may also regard as a counter E. M. F. generator, to be initially adjusted, so that all of the lamps burn brightly; then within limits of considerable range the current will be kept steady even though the applied E. M. F. fall or rise, or though the external resistance of the circuit be varied by lighting or extinguishing lamps.

For if lamps be extinguished and their branch circuits be opened, the external resistance rises and the current falls. It is true that the reduced current has not now so many branches to divide through, and that therefore self-regulation even without counter E. M. F. might be expected, but in systems of considerable magnitude it is not found to act practically, as well as it theoretically should. But here the useful effect of our self-induction regulation comes into play; and since the current acting upon the regulator is lowered, it is caused to develop a counter E. M. F. of less value, and thus to oppose less energetically the applied E. M. F., which therefore is brought to a greater extent into action, to overcome the increased resistance, and to maintain the normal current for the remaining work. So, if the applied potential falls, the current in consequence falls with it, and the counter E. M. F. developed falls also, and enables more of the applied E. M. F. to come into action. And the converse is true, if the current in the circuit from any other cause rises. Such an appliance would be still more convenient in connection with an arrangement of arc lamps fed by alternating currents, and connected up in parallel circuit, since the resistance of arc lamps would constantly be changing,

[10] Sturgeon's Annals, Vol. i., pp. 290-302.

This has been so prominently brought before us by its most modern employment, namely by its well-nigh involuntary use in the distribution of electricity by means of alternating currents and transformers or converters having their primaries connected in parallel between the two mains of the source; and by the inductive resistance regulating device, patented by John Hopkinson, in England, August 3, 1881, No. 3,362, and in the United States, November 5, 1889, No. 414,541,—that many persons have actually been led to believe that such use is really a new thing.

The employment in the regulation of electrical distribution of counter-electromotive forces set up by the working currents themselves and proportioning themselves automatically to the work being done, is one of the most valuable and interesting features of modern electrical work; and, though such regulation requires to be supplemented by auxiliary arrangements, and though the belief of some that it could be attained absolutely without any waste has not been completely realized, still by availing ourselves of this feature we are enabled to control electricity with a facility and under conditions which otherwise would be unattainable.

The Hopkinson invention consisted in associating with an arc or glow electric light circuit employing alternating currents, a variable inductive resistance. This in one form was made by coiling a ribbon of thin sheet iron into a ring form, the different layers being separated by an insulating layer, and then by winding a number of coils of insulated wire on this ring, their adjacent ends being connected with plates between which contact plugs could be inserted, so that any number of the coils could be introduced or cut out from the circuit. Another form embodied the same principles, but had not a closed core. This form had a horse-shoe core made of an electromagnet formed of layers of sheet iron insulated from each other. The legs of the core are surrounded with the coils, and the said core has an armature also made of insulated layers of sheet iron. In this form the armature is clamped down; but the regulability of the appliance is attained by moving the magnet core further into, or withdrawing to a greater or less extent from, the surrounding coils. The form first described is in the British Patent shown as being included in circuit with the two mains of a dynamo; incandescent lamps being in cross bridges between the said mains; while in another figure arc lamps are in parallel circuit with the mains, an inductive resistance being included in each branch for each lamp and acting as an equalizer.

The iron core closed on itself to form a complete magnetic ring in which the lines of force are concentrated through the coil, and forced to cut all convolutions when exposed to reversals; the laminations at right angles to the currents, acting to facilitate magnetic change, to diminish hysteresis, and to prevent the circulation of eddy currents; and the insulation of the said laminations aiding in the latter function; all tend to show that this is a very highly organized appliance and is not only well adapted to produce a very high degree of self-induction, but combines most of the best arrangements tending to that end, and it is therefore not suprising that its invention and use made a strong impression upon the electrical mind, and caused a revival of the idea that regulation on these lines was capable of being accomplished, to use the words of the patent, "without wasting energy." Without materially wasting energy would perhaps be more strictly accurate, for by its use a small amount of actual resistance coil is enabled to do the work of a very much larger amount.

I have certainly no desire to detract from the great merit of this application, but an honest chronicler has no choice and must say what has been done, and it must therefore be stated that inductive resistances and other self-induction appliances had long been used both experimentally and commercially; no doubt often with but an imperfect conception of their mode of operation.

[11]Poggendorff's researches into the action of induction coils disclose a remarkable state of affairs for so early a date. These show that one induction coil was employed to send a current through the secondary helices of two others. The first coil thus acted as an alternating generator, and the two others as inductive resistances.

The primaries of two induction coils were connected in parallel and also in series at different times. Thus, to quote Poggendorff's own words, "two instruments (induction coils) A and B, were so combined that the current traversed the two primary coils one after the other; the induction coils (secondaries) however, were separated and A was allowed to give sparks, whilst B remained unclosed and without a soft iron core; the introduction of the latter into B, weakened the sparks of A, and the subsequent metallic closing of B reproduced their former strength "

The proper arrangement of induction coils is then discussed and whether the primaries should be connected in series or in parallel circuit. It is shown that the latter way is the proper one, and why. Then the paper goes on to say: "With respect to the cause of these phenomena it is no doubt to be sought in the extra or inner induction current. The outer induction current which is produced by breaking the inducing current has the same direction as the latter; whereas the extra current, which is at the same time excited in the induction wire, has a tendency to weaken the first induction current, and the more so the stronger the extra current, which latter is especially strengthened by the soft iron core.

"Consequently when the primary coils of A and B are connected one after the other, it is clear that the insertion of the soft iron core into that of B, will strengthen the extra current in that of A, and therefore weaken the induction current of the latter instrument.

"By connecting the instruments side by side a close circle is at once formed by them, and the extra current produced by the insertion of the soft iron core into B acts against that in A, and may therefore, when both are equal, completely neutralize it, when the outer induction current of A will necessarily be strengthened.

"Without the circle formed by this combination, *i. e.*, in the wire leading back to the voltaic battery, the two extra currents act, of course, in the same dir ction and strengthen one another, in consequence of which the sparks at the current breaker are still very active."

These considerations of Poggendorff show that even at this early period a great flash of light was thrown into the darkness which hitherto had obscured the reactions of self-induction, and though we have largely failed to use that light until quite recently, this is chiefly attributable to the same oft recurring reason, that there was really little call for it; hence it was soon hid under the bushel of the results of research on other subjects of more immediate interest.

The statement which I last quoted, brings me again to the application by Fizeau of the condenser as a shunt to the vibratory break, and to its operation.

[12]As shown by Lord Rayleigh, the condenser operates by producing electrical oscillations, and in its action the spark at the contact breaker is greatly decreased and the spark between the secondary terminals greatly magnified, because at the break the condenser is virtually an inductive reservoir, being an electrostatic shunt. And being an electrostatic shunt, the energy it momentarily absorbs is returned reversely to the primary circuit, just as in the discharge of a secondary cell, and increases the inductive variation in the secondary circuit during the brief period of time immediately after the break. And as the electromotive force in the secondary is thus exalted it is not difficult to see why the condenser increases the sparking distance.

As early as December 6, 1862, a patent for cable working, No. 3,453, was taken out by C. F. Varley, which describes the use of a self-induction resistance. This patent says: "A second circuit from the cable to the earth, independent of the receiving instrument is formed, by means of a resistance coil with a large iron core. It may be advisable to connect the cable to earth through an induction coil consisting of a large bundle of iron wire, surrounded by a long length of fine wire, the action of which is as follows: On reversing the battery connections the induction plates (condenser) and battery combined, send a short impulse into the cable, which divides; one portion into the cable, the other through the induction coil to the earth. At the first moment, the iron of the core opposes the passage of the current; consequently, during the first instant of time nearly the whole force of the current is applied to the cable. As the iron becomes magnetized to its maximum, this opposition ceases, but the plates have been charged in the opposite direction, and there is no longer any current passing from them into the cable to maintain the magnetization of the iron, the demagnetization of which, induces a current in the coil, and discharges the cable. In this way each impulse is followed by a short impulse in the opposite direction One of the figures of the patent shows that the wires of the core are made long, and are turned back on all sides over the wire of the coil, so as to entirely encase it. This feature was in conformity with a previous British Patent, No. 3,059 of 1856. The arrangement however clearly shows a use of a self-induction coil as a current controller, and indicates the function of a large iron core.

[11] Poggendorff's Annalen, Vol. xciv., p. 2, and London and Edinburgh and Dublin, Phil. Magazine, 1855, Vol. 10, 4th series, p. p. 136-137.

[12] Phil. Mag., Vol. xxxix., p. 428, et seq.

We next find the counter E. M. F. of self-induction coming into use in connection with fast telegraph systems. Arrangements for its use are shown in the United States patents granted to Mr. Edison. These are respectively, No. 135,531 of February 4, 1873; No. 141,773 of August 12, 1873 and No. 147,313 of February 10, 1874.

The first and second disclose a shunt circuit, including an electro-magnet connected round the receiving instrument of a chemical telegraph. The first also shows a leak to earth from the line, which leak includes an electro-magnet. In both cases the object is to utilize the discharge current developed by the electro-magnet in the regulation of the operation and to produce sharp and clear signals.

The third describes the use of electro-magnets in shunt circuits round the transmitting and receiving instruments of an automatic telegraph system, and is said to be an improvement on the first. A number of electro-magnets are shown and by means of a switch one or more of these may be introduced. In other words the inductive resistance is here adjustable, and is operated by breaks, not by reversals.

British Patent No. 3,935, Nov. 14, 1874, to Alexander Melville Clark, for a chemical copying telegraph, uses induction and other coils to clear a line by the self-inductive counter E. M. F. By the decrement or cessation of the impulse, (as the patent states) the strongest depolarizing effects are produced, and the line is successfully cleared.

Next come four other patents to Thos. A. Edison. These are: U. S. Patent, No. 168,243, of Sept. 28, 1875, for an automatic telegraph. This, as in the previous cases, employs an electro-magnetic shunt.

U. S. Patent, No. 168,385, of October 5, 1875, Duplex Telegraph. This is an excellent example of self-inductive regulation. The counter E. M. F. is developed from electro-magnets in a changing electric circuit, and the coils have cores closed on themselves.

The next two, No. 173,718, of February 22, 1876, for Automatic Telegraphy; and No. 178,221, May 30, 1876, Duplex Telegraphy, involve no new principles and are like the preceding ones.

[13]Much information regarding the subject and further examples of its practical application can be found in a particularly able paper on "Shunts," read by William H. Preece, before the Society of Telegraph Engineers in 1887. The subject of the counter E. M. F. developed in electro-magnets is discussed, and the increase of the same, when the iron core is endless, is determined and pointed out; a good many instances of the practical uses of the self-induction shunt are described.

U. S. Patent, No. 207,724, of September 3, 1878, granted to Thos. A. Edison for a Duplex Telegraph, shows an electro-magnetic coil and closed magnetic circuit core placed in each branch of a Wheatstone bridge duplex telegraph, to counteract by its counter E. M. F. of self-induction the discharge of the electro-magnets in the bridge circuit. In Culley's "Handbook of Practical Telegraphy," London, 1878, p. p. 303 to 304, also p. p. 305 and 411, the regulation of currents by inductive resistances is considered.

In the first instance, the counter E. M. F. of an adjustable series of electro-magnetic coils is used to delay the discharge of a condenser in a duplex system. This is closely analogous to the function of the Hopkinson device, and is very suggestive. The reference on page 305 states that "static discharge can be entirely compensated for by the use of an induction coil, or a series of electro-magnets instead of a condenser."

U. S. Patent, No. 227,039, of April 27, 1880, to Muirhead and Winter, for a Quadruplex Telegraph, describes electro-magnetic shunts for reversing keys and relays, which are to counteract by their discharges electrostatic retardation. The specification says: "The electro-magnets may be of the well-known closed horse-shoe form, or they may consist of a single rod of soft iron with flanges of soft iron and a cylindrical casing of iron closing over the wire and connecting magnetically flange with flange."

U. S. Patent 231,904, September 7, 1880, to Joseph E. Fenn, Duplex Telegraph, shows an electro-magnetic generator of counter E. M. F. in the line circuit to counteract effects of discharge. It is made with a closed magnetic circuit, a separate coil being on each leg of a multiple pole core; several of these poles are made with yokes, and the combined yokes can be made magnetically continuous or discontinuous, at will, by means of iron plugs which can unite the different sections of core.

A book published in 1880, by Louis Schwendler, and entitled, "Instructions for Testing Telegraph Lines, and the Technical Arrangements of Circuits," Vol. 2, p. p. 144-147, gives a description of an electro-magnetic shunt and its operation. It is made like an ordinary electro-magnet, but has an adjustable wedge-shaped armature in contact with the cores. This of course operates by utilizing the counter E. M. F. of self-induction which developes currents that circulate through the shunt, and sharpen the signals.

In telephony also, as in other fast systems employing rhythmical currents, the counter E. M. F. has by no means been idle. As in telegraphy, our early acquaintance with it was an unpleasant one. Many of the earlier telephone lines were connected with a number of stations, and at each station there was of course an electro-magnet to operate the call. In some cases this was a telegraph relay, and in other cases a bell magnet. But in either case it was found, as indeed might have been anticipated, that the telephone currents had a decided repugnance to pass through the intervening electro-magnets on their way from one station to the other. To quote the graphic words of one of the patentees of devices intended as remedies for this trouble, it was found that electro-magnets were to a large extent "opaque to telephone currents."

Of course this is due to self-induction. The resistance of the line or the magnet coils had little or nothing to do with it. The convolutions however had, since it is clear that the electromotive force of the self-induction was proportional within certain limits to the number of convolutions.

The same difficulty appeared also in exchange work, where between any two connected lines was interposed an annunciator, to give from either end station a disconnecting signal. Several devices have been suggested for the removal of this difficulty and some of them have been patented.

Elisha Gray shunts the several interposed magnets by condensers; vide United States Patent, 203,264, of May 7, 1878.

F. W. Jones, attacking the same difficulty, shunts the interposed magnet by a non-inductive resistance controlled by the armature of the signaling magnet. See United States Patents, 238,399, of March 1, 1881, and 238,912, of March 15, 1881.

Other devices have also acted to shunt the bell or annunciator magnets in different ways; and still other suggestions have been, to surround the iron core with a brass sleeve, or with a closed circuit consisting of one layer of insulated wire; but these last, while certainly reducing the retardation, reduce also the magnetic power of the appliance. And there is no remedy so effectual as the absence of the interposed electro-magnet.

The service rendered by self-induction in telephony, and that which still may be expected, fortunately will probably outweigh the ills which it introduces. In many switchboard installations for metallic circuits, the supervising telephones are looped or bridged across between the two conducting links which unite one of the two metallic circuits with the other, and their self-induction prevents a material loss of current. Where from some condition of the service, such for example as the requirement of supervising both metallic and earth return circuits at the same switchboard, it sometimes becomes necessary in bridging the telephones to attach an earth branch to the connecting link on one side of the instruments; in this case it has also been found necessary in practice to place coils containing iron cores on the other side of the earth branch, so that not only the resistance but also the self-induction may be balanced.

It has also been ascertained that many telephones can at different stations be placed across from one wire to the other of a metallic circuit without any perceptible diminution of the effect at any one of them. This is one of the most important results of the self-regulating attribute of self-induction.

Perhaps, however, the most valuable instance of turning an electrical enemy into an electrical ally, is the way in which, by the proper use, construction and arrangement of electro-magnets, a plurality of either telephonic or partially telephonic and partly telegraphic messages may be transmitted over the same circuit at the same time.

The pioneer in this kind of work was C. F. Varley, who as early as 1870 took out a patent, No. 1,044, in England, for a combined simultaneous ordinary Morse and harmonic Morse transmission over the same wire; in this system the straight Morse was worked through electro-magnets, while the harmonic branches were led off from the main line from points outside of the electro-magnets.

Carrying on this line of invention, Mr. Van Rysselberghe, of Belgium, and Dr. Rosebrugh, of Toronto, Canada, have worked out systems whereby telegraphy and speaking telephony can be at the same time operated over the same circuit.

Since, however, there is enough in either system to fill up a paper devoted to them exclusively, and since this paper is already too long, I find it impossible here to describe them in detail, reserving this possibly for some future occasion.

Self-induction has also been caused to aid in eliminating the disturbing results of extraneous induction caused by parallel circuits, as in the United States Patent of Mr. Edison, No. 203,019, of April 30, 1878, where a telephone circuit is freed from external influences by combining it with an induction coil connected with the disturbing circuits in such a manner, that the direct disturbances received in virtue of the parallelism of the contiguous circuits is neutralized by an equal and opposite induction received also from them through the induction coil. This, however, is not a practical expedient.

Closely analogous to the self-inductive regulation of which I have been speaking, is that upon which the efficiency of an electro-motor depends. This was first observed by Jacobi[14] who says:

"Experimenting on the magnetic force of a bar of soft iron for which I could in no way account, I sometimes found considerable differences for which I could in no way account. I was curious to know if these differences proceeded from the nature of the iron, or from the weakening of the electric current produced by a voltaic pair of half a foot square of surface. For this reason, I placed in the circuit a galvanometer so distant as not to be affected by the direct magnetism of the bar. I was much astonished to see the needle recoil on placing the armature and advance on removing it, for it was the first time I had known the double quality of the connecting wire, viz., that of constructing the voltaic current, and at the same time representing an ordinary wire subject to the action of a magnet in motion. The spiral producing a magnet by the voltaic current is at the same time a magnetic electrical spiral in which a magnet is placed.

---

[13] Journal of Society of Teleg. Engineers, London, 1877, p. p. 40-69.

[14] Sturgeon's Annals of El'y, 1837, Vol. i., pp. 408-419.

"Hence the solution of the uniform velocity of the magnetic machine. For being, set in motion by the magnetizing power of a voltaic current, it represents simultaneously an apparatus composed of magnets in motion and capable of producing a magnetic electrical current in a direction opposite to that of the voltaic current."

Jacobi, in a subsequent paper, practically elucidated the principles of the operation of counter E. M. F. in electro-motors, even as now understood, although he possibly did not state them as we now would. But he clearly showed that a motor may be regarded as a dynamo acting to develop an electromotive force, opposite in direction to that acting upon it, E. That the resultant force was of course $E-e$, and that this together with the resistance of circuit determine the strength of the current. That the motor utilizes $C\,e$ of the electrical power supplied, $C\,E$; and he furthermore showed that the power developed by the motor $C\,e$, is at its maximum when e equals one-half E.

It may be thought by some that considering the title of the paper, the principal utilization to which I have referred, viz., the use in regulation of systems of alternating currents operating converters, should have been discussed. It does not seem to me that it is necessary; this has often been done, and will again often be done by others much more competent than myself to handle the subject. But it does seem right that one should be found to give due credit for those who in the same line of thought are "not lost, but gone before," and I am glad that I am in a position so to do.

There seems little need for me to cite any more instances, showing that like nearly all new arts, the art of regulation by means of self-induction and of otherwise usefully employing the counter E. M. F. due thereto, is not *quite* new, and that while we can congratulate ourselves upon the achievements of the present, we should not fail to respect the foundation layers of the past, for of a truth, there were giants in those days.

ELECTRICITY IN THE NAVY.[1]

BY GILBERT WILKES, U. S. NAVY.

I HAVE taken as my title "Electricity in the Navy," and shall give in my paper the general conclusions derived from five years' more or less intimate connection with the application of electricity in our naval service.

The electrical engineer has little to do with the placing of the dynamo room, which is of necessity governed by the arrangement of the ship as a fighting machine. I shall, therefore, merely consider the power and apparatus of the plant, commencing with the engines.

Both in this country and abroad compound condensing engines have been used, some having separate condensers, some exhausting into the main condensers of the ship; but the preference seems to be in favor of simple double acting, high speed engines, the reason being that the power used for electrical purposes is so small in proportion to that of the main engines of the ship (only about an average of one per cent.) that the saving does not pay for the additional complication and cost. However, with a given plant, the engine should be constructed to allow little variation of speed under large changes of steam pressure, in order to take advantage of the main condenser when possible.

In our service both horizontal and vertical engines are now in use, the preference in some cases being the result of the shape of the available space. No data has yet been obtained as to the most economical type, but both are doing good service, the mishaps having been due to accidents. Of late years all of the engines put in for electric lighting have been high speed, the largest of about twenty-five horse-power and running at 400 revolutions.

The important points in the consideration of a marine dynamo are:

FIRST. It should be direct driven. The reasons are obvious, as not only is the space taken up by the belting valuable, but in a sea way the danger of running belts must be considered, especially when it is taken into account that naval vessels are fighting machines and the possibility of accidents must be reduced to a minimum.

SECOND. It should be compact. This is a natural extension of the above. Even now it is difficult to find room for all the machinery, stores and ammunition, besides providing room for berthing the crew on a modern man-of-war.

THIRD. It should be free from liability to injury by salt water, and not too subject to mechanical damages.

In this respect there remains room for considerable improvement, the latest dynamos now better filling this requirement than did the old "L" machine on the Trenton in 1883, the first dynamo afloat in our navy, and which ended its useful career in the great storm at Samoa last year, when it ran until the water had put out the fires under the boilers.

On board ship salt water and damp air get everywhere, and within the last year a number of cases of slight burn-out have occurred in armatures, which, when installed, measured high in the hundreds of thousands of ohms insulation. The dynamo should not be easily harmed. The dynamo room is now always low down in the ship, under the protective deck (if there is one), and when the light is not in use the room is very dark, rendering careful inspection difficult.

FOURTH. The dynamo should have small effect upon the compasses. This point has received little attention, though it is a matter of great importance, as the effect on many vessels is so large that, in order to work up the day's run, it is necessary to know the hours during which the dynamos have been in operation. Complete deviation tables are, therefore, necessary for the two cases. In different types of dynamos the effect with a twenty horse-power machine, at a distance of twelve feet, will vary from less than one-twentieth of the horizontal component of the earth's magnetism to several times the strength of the horizontal component. The latter is, unfortunately, rather the rule than the exception, and, in consequence, the position of the dynamo room has to be well borne in mind in locating the standard compass.

FIFTH. It should be easy in running and require but little attention. The machine should be non-sparking, under constant load and also be able to stand sudden large changes of load with little sparking. This is necessitated by the fact that the dynamos now supplied for incandescent lighting are also used for search light work, and the conditions are aggravated by most of the search lights having hand regulation only. Thus, with a 200 ampere machine, not only are from 50 to 100 amperes thrown suddenly on and off, but, at the moment that the operator at the projector brings the carbons together, the dynamo is suddenly called upon to deliver over three-fourths of its total capacity.

SIXTH. It should be efficient and run cool, the former in order to avoid the waste of energy and a corresponding amount of the coal supply, and also in order to avoid overheating. The dynamo rooms on ship board are, at best, warm, notwithstanding the motor fans, which are now usually supplied, and thus the safe limit of extra heating is reduced. At the same time consideration for the attendants requires that the cramped space be kept as cool as possible.

SEVENTH. The dynamo should maintain a constant potential at all loads. This is of course accomplished by compounding, and, as there is only about 3 per cent. drop, it is usual to compound exactly, or to only overcompound enough to allow for the decrease in the engine's speed with load.

EIGHTH. The dynamo should be light. The reasons are obvious, but it is considered last, because usually a careful study of the materials, and arrangement of the plant, can accomplish more towards reducing the total weight than the strict adherence to a specification of watts per pound of dynamo. Thus, consider the difference between the weight of a 40 horse-power ship plant on a five watts per pound specification and upon a four watts specification. Two 200 ampere, 80 volt dynamos, with their share of the bed plates, will only weigh about 7,500 pounds. Twenty per cent. of this will be 1,500 pounds, an amount a large portion of which can really be saved in some cases by more careful attention to the amount of wire and molding employed.

Naturally no one dynamo can best fill all of these conditions, and while the order in which they are above arranged will usually approximate to their relative importance, special cases arise which demand a re-arrangement. Thus, on torpedo boats, the most important quality is small size. With this in view, numerous devices have been placed upon the market and faithfully tried, but none have to my knowledge proved satisfactory. The requirements of high efficiency, low speed and low heating, all give way in this class of dynamo to the necessity of compactness and light weight. Good results were hoped for from the Parsons turbo-electric generator, but experience at Newport demonstrated that the turbine was so inefficient in its consumption of steam as to place its use out of the question. There is as yet no apparatus to satisfactorily fill this want.

Up to the present all of our ship plants contain two or more similar sets, each composed of an engine and one direct driven dynamo. The larger of these are of 200 amperes capacity; a very convenient unit, but one which can be doubled in capacity with advantage in ships which are not light below decks and which are likely to soon have extensive motor application; for example, vessels of the monitor type.

The voltage in use in the navy is 80 volts, this having been fixed upon as a mean between the most efficient pressure for the incandescent system and the voltage necessary for the search lights, to which current is supplied by the regular service machines. The incandescent lamps have given excellent results as to life from the very start, owing in great measure to the fact that low efficiency lamps are always used, nothing more economical than 4 watts per candle-power being usually required.

---

[1] A paper read before the American Institute of Electrical Engineers, New York, May 20th, 1890.

Search lights of 50 volts and from 50 amperes up are used, 2 or more being supplied, according to the size of the ship. Some of these are imported, others are made in this country.

The two wire system has always been used in the naval service, the ship never being allowed to form the return circuit. On account of the present beginning of motor work on board ship and the future developments confidently looked for, the direct current has always been used. Motors have thus far been used only in driving small fans up to one-half horse power, for hoists, and in one case a motor has been used for training one of the large guns—on the "Chicago." There are numerous small engines about a man-of-war, varying from 1 to 50 h. p. Some of the smaller ones might even now be replaced with advantage by electric motors, but it must be proved in each case, that the motor not only does the duty as well as the engine it replaces, but also that it and any increase necessary in the generating plant take up less room and weigh less than the engine and its piping. This, of course, will always be the case where very small engines are replaced, and as the tendency is to increase the capacity of the dynamo plant, it may not be long before motors may look for a larger field on board ship.

All circuits are water tight from dynamo to point of distribution, the cut-outs having stuffing boxes through which the lead covered wires enter. Even the switches and attachment plugs for portables are required, in certain places, to be water tight.

One electrical application that presents many advantages on board a man-of-war, especially when on a foreign station, is electrical welding. However, when it is introduced on ship board, the pressure of the generator should be reduced to 80 volts, in order that in case of emergency it might be used for lighting purposes, while the welders should have several sets of adjustable clamps. Welding machines have not yet been actually used on ship board, but it is to be hoped that their introduction is a development of the near future. They cannot supplant any of the existing dynamos, owing to the necessity of motors, but must come in to occupy a place of their own, to almost entirely supplant the ship's forge and add to the general useful equipment.

Thus the man-of-war is the proper field for nearly every form of application of electricity, and when the storage battery becomes more suited to the service there required, there is no doubt that it too will come in for its proper share of usefulness.

As to the naval work on shore in the electrical field, little need be said, as the practice at naval stations must be similar to that in ordinary commercial work. However, a navy yard is an ideal place for the erection of a central station for light and power. The streets must be lighted; closely grouped about the station are offices and large shops needing light in the dark afternoons, and power for motor work; then in an outer approximate semi-circle lie the officers' quarters; finally there are anchor chains to be welded, boiler tubes to be repaired, and numerous other similar operations which can be better accomplished by the welder than by any other known means. This in an ideal plant will call for arc lights, incandescent lights, constant potential motors, a welding generator and welders. The complete combination will probably not be realized at any one place within several years, but a good beginning has been made in the arc light plant recently installed for outside and shop lighting at the Washington Navy Yard[2] and the progressive plan adopted by the Department leads us to hope that the shore stations will rapidly receive the benefits already enjoyed on ship board. Owing to the usually close grouping of the buildings and to the demand for motors, it is probable that only in exceptional cases will the alternating current be used extensively. Good use is already being made of small motors for drilling purposes at the New York Navy Yard, where several are in constant operation, having driven out the portable steam engine, countershafting and belting.

The applications of electricity in the navy have always been on the increase, and any one who has served one cruise with oil lamps and one with electric lights and motors will understand the favor in which the increasing use of electricity is held by the naval man.

New Bedford, Mass. Charles W. Clifford, counsel for the Southern Massachusetts Telephone Co., has served papers on President Hart of the New Bedford Street Railway Co. notifying him that the telephone company will hold the street railway company liable for any damage which might result to the telephone system through operating the road by electricity, and Walter Clifford, counsel for the street railway company, has served a notice on the telephone company that it would be held liable for any damage which might result from the telephone wires falling upon the electric railroad wires.

[2] See The Electrical Engineer for full illustrated description May, 21, 1890.

THE LIMITATIONS OF STEAM AND ELECTRICITY IN TRANSPORTATION.[1]

BY O. T. CROSBY.

"Do you expect electric engines entirely to displace steam locomotives on all railroads?" That is a question which has doubtless been propounded to many electrical engineers. Its answer has doubtless been made, in general, by wise reference to the boundless possibilities of direct production of electrical energy from heat, and to Bellamy's "Looking Backward" storage batteries.

To make some study of the boundary line dividing the province of steam locomotion from that of electric locomotion—under existing conditions of producing electric energy—is the object of this paper.

In the light of present achievements I may state, without argument, the following propositions:

First—It is possible to construct motors capable of doing the maximum work required to-day in transportation.

Second—It is possible continuously to generate electric energy equal to the capacity of any number of such motors.

Third—At any desired loss and over any desired distance it is possible to supply by the running contact method, the necessary current, at considerable pressure, for the working of such motors.

Should there still be question in the minds of any, as to the value of the running contact method at speeds much higher than those commonly used, I may state that I have seen 75 amperes at 500 volts thus continuously supplied to a car moving at more than 110 miles an hour.

These premises being established, further discussion divides itself into three parts.

First, as to the mere possibility, without reference to the economy, of steam and electric propulsion under given conditions.

Second, as to the relative cost of exerting, in a locomotive, any unit of power by electric, as compared with direct steam motors.

Third, as to the relative amount of power required by the two agents to transport a given paying load under given conditions.

In using the word steam, as above, I have in mind only the direct application of steam power on the tracks. The case of cable propulsion is not here compared, as that has, within its restricted field of application, already been compared with horse, steam and electric power.

The limiting possibilities of locomotion may be understood by considering a prolongation of the lines of present practice in the direction, first, of loads handled; second, grades climbed; third, speeds attained; fourth, length of continuous runs.

Since the effect of grade, as compared with line, is simply to increase the tractive effort required for a given load and speed, it need not be separately treated, except that there has been some question of increase of adhesion, in the ground return method, which in extreme cases might appear as an advantage for electric propulsion. The matter is not of great importance, and I will refer to it only so far as to say that interpreting my own general experience and some special tests, the adhesion coefficient seems not increased in any practical degree by the mere passage of the current from wheel to rail.

The capacity of an electric engine, like that of a steam engine, to haul any given load, will be measured by the tractive effort possible to be produced and the relation between weight and adhesion for given track conditions. The ready multiplication of cylinders in the one case and armatures in the other, while maintaining mechanical unity as to drawbar division and the ready coupling of distinct locomotive units, renders the whole question of capacity to exert a given horizontal effort, without regard to the time element, unimportant and indefinite.[2] It goes without saying that, if desired, a single armature may be constructed capable of exerting as great a drawbar strain as any locomotive now in use.

As to limiting speeds, it is not easy to-day to make "an educated guess" either for steam or electric propulsion. The high figures for steam that have been recently presented, both from England and America, are higher than the limiting figures as they would have been given by many competent authorities only a few years ago. Eighty-six miles per hour in England, on the Northeastern Railway, eighty-seven miles per hour in this country on the Reading Railway, have both been reported since Jan. 1, 1890. These runs are noteworthy, not only for the fact of unusual

---

[1] A paper read before the General Meeting of the American Institute of Electrical Engineers, Boston, Mass., May 20, 1890.

[2] As an interesting example of an unusual load in steam service, I may refer to one consisting of 156 loaded cars and two cabooses, hauled over the Mississippi Valley Railway, December, 1885. The load consisted of—

	Pounds.
Cotton weighing.	3,226,000
Cars weighing	3,239,000
Engine and tender weighing	147,000
	6,612,000

Speed was about 10 miles per hour.

speed, but because, as shown by indicator cards in the English case, and as may be deduced from the consideration of the maximum cylinder power in the American case, the train resistances are far below the values that would have been predicted by even the most liberal of the received formulæ on the subject. The total resistance per ton, as per indicator card in the 86-mile run, was only 13.4 pounds. According to Searles' formula, adopted by Wellington, it should be 69 pounds, engine and tender being taken at 50 tons. The load of 347 tons was carried at 86 miles per hour by an expenditure of 1,068 h. p.—this on a level. The engine was compound.

Would it be possible to attain a speed twice as great, or say 150 miles per hour?

A driver 24 feet in circumference would require to revolve 550 times per minute in order to travel 13,200 feet per minute, or 150 miles per hour—this without slip. Since in the case considered the revolutions per minute reached 309, and since in the Reading case a much higher rate must have been reached, the drivers being smaller, and since on stationary engines a speed much above 550 revolutions per minute has been attained, it seems beyond question that from this point of view the supposed case is quite possible.

Considering the matter of steam supply, we are again brought to consider the whole matter of train resistances at all speeds.

Total resistance to motion should be sharply divided into two classes: the resistance due to motion through air, and that due to friction and blows between vehicle and track, and to friction and blows between parts of the vehicle.

For the most part those who constructed the formulæ now found in text-books, worked on roadbeds far inferior to the best work of to-day, at speeds much less than those now attained and with wrong values for at least one of the species of resistance, the atmospheric. On this point I have recently been able to present as the results of experiments at high velocities, made by Mr. Benj. J. Dashiell, Jr., and myself, a formula showing the pressure to be a function of the first, instead of the second, power of the velocity as ordinarily assumed. A convenient datum point may be given stating that at 100 miles per hour the pressure on one square foot, normal to the direction of motion, is 13 pounds, while proper shaping of the front may reduce this 6.5 pounds.

The absolute values given, while corresponding quite closely with those of received formulæ in the neighborhood of the velocities heretofore experimentally attained, depart widely from those assumed for velocities higher than 30 miles per hour, and calculated by the quadratic relation between velocity and pressure. Using the more trustworthy values, I have been able to separate more nearly than has heretofore been possible the atmospheric from all other resistances met at high velocities. Some inaccuracy still remains, by reason of the difficulty of obtaining exact measure of the resisting areas in a train, but I have been able by study of careful tests made by others on the N. Y. Central and on English roads, to find that over the range from about 40 up to 80 miles per hour the tonnage coefficient seems practically constant at 8 pounds. This, of course, applies only to first-class roadbed and rolling-stock. Whether this coefficient remains constant at higher speeds we do not know. There is no reason to assume, as has often been done, that it increases with the square of the velocity, and on the other hand it will not be safe to assume constancy. From experiments made with a single 2.5 tons car at about 100 miles per hour, the tonnage resistance at that speed seems to be about 20 pounds per ton. Though this value seems quite high as compared with the eight pounds at 80 miles per hour, the difference is in large part to be explained by the poor condition of the track used for the experiment and a constant curvature which would call for about four pounds per ton. Until better evidence can be had it will be safe, at least, to assume a value of 20 pounds per ton, on a first-class track, with good rolling-stock, at 125–150 miles per hour.

Having made this necessary digression, we may return to the matter of steam supply, and state that by reducing weight and area, both to something less than one-half the original values in the 86 mile run, the same effort would produce the speed 150, instead of 86. The area cannot be thus reduced, but by assuming a greater reduction in weight—say to 100 tons, or to little more than engine and tender—maintenance of the higher speed becomes possible, with nearly the same steam expenditure as in the recorded case.

To attain that speed, from rest, might require such original weight of fuel and such length of favorable track as to make the feat practically impossible with steam. This leads us to inquire into the dead weight necessary for hauling, say, one ton at different speeds.

Table I. gives the horse-power required for exerting the tractive effort for one ton at various speeds, at various efficiencies, with various values of cross-section per ton, and with the two agents—steam and electricity:

Column 1 shows speed in miles per hour from 20 to 140; column 2, corresponding tonnage coefficient, or resistance, in pounds per ton, inclusive of atmospheric resistance. Columns 3 to 8 inclusive show horizontal effort needed for overcoming atmospheric resistance under various assumptions as to area exposed per ton, from 1 square foot to 0.1 square foot per ton. The former figure corresponds nearly to the case of a heavy locomotive propelling itself alone. As load is put on behind it, other ratios are formed. Oblique surfaces are supposed to be reduced to equivalent normal surfaces. Columns 9 to 14 inclusive show rate of work in horse power per ton, for the various cases of area exposed to atmospheric resistance, efficiency of locomotive being taken at 90 per cent. Columns 15 to 17 inclusive show h. p. per ton for the extremes and middle cases of exposed area, and for locomotive efficiency of 80 per cent. Columns 18 to 20 inclusive show same for efficiency of 60 per cent. Columns 21 to 26 inclusive show weight of coal and water per ton carried for one hour, assuming 5 lbs. of coal and 15 lbs. water per h. p. hour on a steam locomotive. The coal figure is very close to actual practice. The water figure is less, but makes allowance for scooping water at convenient intervals. Continuous scooping is not considered practical or economical. Columns 27 to 29 inclusive show weight of steam locomotive and tender required to generate the required h. p. per ton, under the assumption of 100 pounds per horse power and 90 per cent. efficiency. Only three cases of exposed area are taken; that is, one foot, one-half a foot, and one-tenth of a foot per ton. The weight of steam locomotives is not calculated for any other efficiency figure than 90 per cent., as this seems to be quite constantly attained or surpassed. The assumption of 100 pounds per horsepower is closely true for many good types of locomotive when working at speeds from 60 to 80 miles. At lower speeds this figure is too low, but it is assumed that for any ruling speed engines may be built of minimum weight for that speed. In passing through lower than ruling speeds, both electric and steam motors work at low output per pound of weight, hence the assumption of constant weight per horse-power will not introduce error materially affecting comparative results. At higher speeds than 80 miles existing engines would show less than 100 pounds per h. p.; but as their boiler capacity is reached at that speed, the necessary increase for any regular work would carry the weight figure to very nearly the figure given for the 60 to 80-mile running. Columns 30 to 32 show weight of steam locomotive and tender, plus weight of fuel and water, per ton hauled, also weight of load-freight and freight car that may be hauled; by such weight of motive power; the load figures being obtained by subtracting the motive power weights from 2,000 pounds. Columns 33 to 41 show corresponding figures for electric locomotives under the assumption of 60 pounds per h. p., and at the three efficiencies, 90, 80 and 60 per cent.

The 60 pounds per horse-power covers weight of containing car for motors. I cannot here go into detailed figures on this point, but believe that any investigation will find the figure safe, supposing always that the unit be, say, 25 h. p. or more. I also know of experimental work now progressing under most competent direction, which gives fair promise of leaving this figure much too high. Columns 42 to 53 inclusive show the horse-power required to be exerted for hauling one ton of *load, i. e.*, freight and freight car, the relation between these two being taken as the same for either steam or electric propulsion; hence not necessary to enter here. These columns apply to steam at 90 per cent., and to electricity at 90, 80 and 60 per cent., and for the three cases of exposed area. They are readily obtained from the previous columns by making allowance for the horse-power necessary to haul that part of every ton, total weight, which must go into motive power, machinery and fuel. Columns 54 to 62 inclusive show the ratios between horse-power required by the two agents for hauling a ton of *load* (frieght and freight car) at the different speeds, efficiencies and area relations.

It is plain that if we can now obtain the ratio of cost per horsepower hour, as given by the two agents, in the corresponding cases, we can easily determine the speeds at which the one or the other agent becomes the most economical.

Let us first obtain the cost in electric propulsion.

For this, form Table II., showing the elements in the cost of one horse-power hour in stations of various capacity—from 100 to 3,000 h. p. Engineers and dynamo-men are assumed to receive 40 cents per hour, and to superintend a maximum of 1,000 h. p. This would produce, in some cases, fractional engineers, as for a 1,500 h. p. plant, but such complication has been avoided by assuming a constant value per unit of power, in the pay-roll element in plants exceeding 1,000 h. p. Firemen and helpers are taken at 30 and 25 cents per hour, respectively. Superintendence, at 30 cents per hour, is apparently low, but is equivalent to 60 cents for daylight hours, since the plant is able to run 24 hours with the same general superintendence as for 12 hours. It is further supposed that the total of this item will not require increase until the capacity reaches 3,000 h. p., beyond which it remains constant per unit of power. As no other element of cost is supposed to vary beyond this point, the table shows here a minimum total cost per unit, and a constant cost beyond it.

Coal is assumed to cost $3.00 per ton, and to be consumed at the rate of 3.2 pounds per electric h. p. hour in the dynamo. A very slight error is made in taking the rate of consumption as constant while changing the capacity of the engines.

Cost of steam plant is taken to vary from $50 per h. p., in a small plant, to $20 in a plant of 1,500 h. p. This latter figure may

TABLE I.

seem too low to some, but I have recently seen the figures for an 800 h. p. plant, in a neighboring Massachusetts city, which cost, in place, at the rate of $22 per h. p.

Dynamo plant is taken to vary from $50 to $20 per h. p. in going from 100 to 1,500 h. p. I know that machinery of good design can be manufactured for these prices.

The cost of buildings is taken to vary from $25 to $10 per h. p. This is the most indefinite item. Interest, maintenance and taxes are roundly assumed at 10 per cent. per annum on the whole plant.

With Table II. as a basis, Table III. has been calculated, giving total cost per horse-power hour in stations of various capacities, working at various percentages of full capacity and for 24, 18 and 12 hours per day, respectively.

TABLE II.

Elements of the cost of one h. p. hour, electric, in cents.

A glance at the table shows that in a 100 h. p. plant the cost varies from 2.42 cents for a 24-hour run at full capacity, to 8.06 cents for a 30 per cent. output continued only 12 hours per day.

This extreme case would doubtless be ameliorated by dropping the superintendence and combining engineer and fireman—though to this the unions might object. This capacity is smaller than need be considered for any steam-line service.

The minimum cost given by the table is 0.816 cent; this for a 3,000 h. p. plant, working full capacity 24 hours per day.

The next element of cost—that of the conductors for the current—is obtained from Table IV. showing investment in dollars for the copper required to transmit one h. p a distance of one mile, at varying initial and final pressures. The constants for this table were thus obtained: Taking a well-known line wire, I find that from No. 4 to No. 000 B. W. G., the average weight-ratio of insulated to bare wire, per unit of length, equals 0.844. When bare copper sells at 15 cents, this insulated wire sells at 20 cents = 22.5 cents on the copper alone, when insulated. If, therefore, we take copper at 25 cents per pound we provide for a very good insulation. The cost of one mil-mile is thus found to be $0.004. Combining this with the familiar formula.

$$C\ M = \frac{16{,}600 \times \text{h. p. transmitted} \times \text{distance in feet.}}{\text{E. M. F. at motor} \times \text{volts lost on line} \times \text{motor efficiency,}}$$

the tabulated values have been determined from the resulting formula:

$$\text{Cost} = \frac{760{,}320}{(E - V)\,V}, \tag{1}$$

in which E = E. M. F. at station, V = volts lost on line; motor efficiency is taken at 90 per cent. and distance at 5,280 feet. The tabular figures give the investment. To reduce to actual cost per horse-power hour, rate of interest and depreciation, and ratio between power transmitted and power possible to be transmitted. For one year the possible horse-power hours = 365 × 24. Take annual interest and depreciation at $\frac{1}{16}$ the investment and ratio of actual to possible power transmitted per annum at 1.0, 0 8, 0.6, 0.4, 0.2, 0.1, 0.05, then the divisor of the tabular number becomes 140.160, 112,128, 84,096, 56,064, 28,032, 14,026 and 7,008 respectively.

It remains to obtain values for the distance of transmission.

Let n = number of miles of line supplied from one station.
h = horse-power required for unit locomotive.
K = maximum number locomotives per mile at any time.

nhK = total power to be transmitted at time of K.
A = percentage of dynamo power lost on line.
$\frac{nhK}{100-A}$ = maximum power to be generated.
$\frac{nhK}{100-A}\times\frac{A}{100}$ = " " lost on line.
b = cost in cents of generating one horse-power hour in station.
r = ratio of average power required to maximum power required.
L = interest and depreciation on supporting structure.

This last may be omitted from the calculation, determining division of line into sections, since it remains the same, whatever that division may be. Omitting this, the expression for cost of transmission becomes:

$$\text{Cost} = \frac{760{,}320\, n^3 h K r}{(E-V)\, V \times 140{,}160} + \frac{b\, n\, h\, K\, A}{r\,(100-A)\, 100}.$$

$$= \frac{5.42\, n^3 h K r}{(E-V)\, V} + \frac{b\, n\, h\, K\, A}{r\,(100-A)\, 100} \qquad (2)$$

Supposing that the time schedule of trains, h. p. required per train, and efficiency of motors be known, and that the initial E. M. F. be in all cases taken as high as the state of the art permits, the only variables remaining in this expression are n, b and A. This latter, the value for the drop on the line, will generally be determined by conditions other than those of strictest economy, as shown by getting a minimum value for cost of transmission We must have a reasonably uniform E. M. F. all along the line, in order that the motors may work satisfactorily. It will not be wide of the mark to assume 10 per cent. as a limiting variation of line potential. This is the figure generally assumed in calculating wire for street railways.

TABLE III.

Total cost of one h. p. hour, in cents.

Output in per cent. of capacity while working.	Hours of work per day.	Capacity of Station.							
		100	300	500	800	1,000	1,500	2,000	3,000

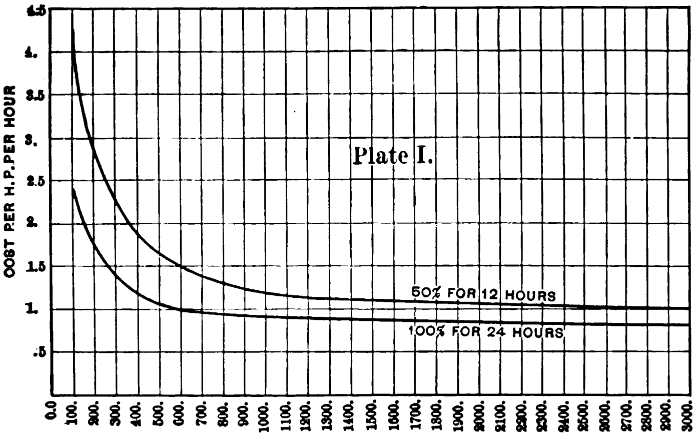

FIG. 1.

The cost of one h. p. hour b must vary with the capacity and conditions of working of the station; hence it is a function of n—*i. e.*, length of unit section, of A, and of that inexpressible variable—the conditions of the service. This stands in the way of obtaining any perfectly general definite expression for n, which, but for this, would result from placing the first differential coefficient of C, with respect to n, equal to zero, and solving to find the value of n, giving a minimum value for C. If trains be run at very short intervals, increase of n would be followed by proportional increase in capacity of station; but, as above shown, this need not go beyond 3,000 h. p. unless the service be so heavy as to require practically contiguous stations of that capacity. If we suppose a case of this short-interval service, so short that a change in n, will not be followed by any change at the station in the relation between maximum capacity and average output, or in the number of working hours, but only in the normal capacity, the relation between b and n for two cases of average output and working hours is shown by Fig. 1. The equation of the 50 per cent. curve from 200 to 1,000 h. p. seems to be very nearly

$$b = \frac{n^2 - 98n + 1{,}000}{12\,(n-100)}.$$

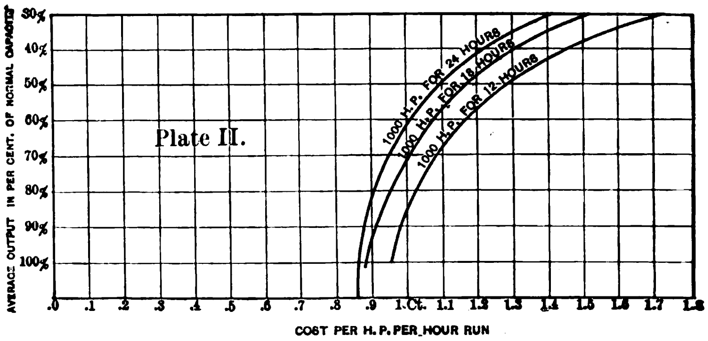

FIG. 2.

If the trains be run at very long intervals, we may require no greater station capacity for 20 than for 10-mile sections; but the relation of output to normal capacity will vary, and possibly the number of hours during which the working force would require to be kept on pay.

Taking the case of a change on average output only, for a 1,000 h. p. station, we have the curves in Fig. 2, for 24, 18 and 12 hours' work. Their equations are nearly of the same form, and are approximately the equations of arcs of circles referred to an origin outside the circle. But each would contain different constants, and would vary more or less from the exact formula for the circle.

If, in the application to a particular case, the algebraic expression for b, above given, or any other resulting from any of the possible progressions through Table III., be substituted in Eq. 2, we may, by differentiation, solve that particular case for the most economical value of n. If the relation between b and n cannot be algebraically expressed, then the proper value for n may be determined by a few trial values, the corresponding values of b being taken from the table.

For the present purposes of comparison, we will assume a case not more favorable than might often be met on busy steam lines, *i. e.*, a station of 2,000 h. p. normal capacity, working 18 hours per day at 40 per cent. of its normal output, the cost per horse-power being 1.25 cents.

To obtain the cost of the line, we will assume that the average distance of transmission is five miles. This would correspond to one station for every twenty miles of road. We will also assume 5,000 volts initial E. M. F. and 10 per cent. drop. From Table IV. the copper investment is found to be 34 cents for one mile. Then for five miles the investment equals $8.50. Making assumptions as to service corresponding to those for the station, we have cost of one horse-power equaling $8.50 ÷ 20,000 = 0.042 cent.

The structure for carrying the conductors may be built for $2,000 per mile. Interest and depreciation would then become $200 per annum. This total is almost wholly independent of the power transmitted, hence the cost per unit of power will vary directly with the number of units transmitted. Assuming a constant distribution of one 500 h. p. train for every 20 miles of line, we have the cost of this item for 1 h. p. hour:

$$20{,}000 \div 365 \times 24 \times 25 = 0.09 \text{ cent.}$$

Reaching the locomotive, we must add, supposing an average output of 500 h. p., 0.08 and 0.06 cent respectively for driver and his assistant. The latter is necessary only as a substitute for his principal in case of emergency, but as such he would doubtless always be placed on trains of considerable value.

Repair on electric locomotives is not as yet well defined. That the repair bill must be far less than in the case of steam locomotives follows almost necessarily from the great reduction in the number of parts, especially of moving parts.

From Mr. Arthur Wellington's very valuable work on railways, I take the figures showing percentage distribution of locomotive repairs, by parts.

Boiler, 20 per cent.; running gear, 20 per cent.; machinery, 30 per cent.; lagging and painting, 12 per cent.; smoke-box, etc., 5 per cent.; tender (running gear, 10 per cent.; body and tank, 3 per cent.) 13 per cent.; total, 100 per cent.

Of these items we may at once, and with certainty, strike out boiler, smoke-box, etc., and tender, thus dropping 38 per cent. of the total. Having no boiler to carry, the running gear will be less in quantity.

The wear will be less, due to the use of rotary instead of reciprocating effort. It will then be fair to reduce this item by half, making another saving of 10 per cent. So in the machinery item, there can be no question that with the rapid advance toward slow-speed motors, reducing gearing, and sounder insulation methods, the great advantage of having only *one moving part* in the motor itself must operate to very largely reduce the repair figure, probably to half its value in a steam locomotive, leaving it at 15 per cent. In lagging and painting, the omission of boiler and other parts must again effect a reduction, say to 6 per cent. The total reduction thus plainly indicated must be then very nearly 70 per cent.

TABLE IV. *For Double Metallic Circuits.*

COPPER INVESTMENT, IN DOLLARS, FOR TRANSMITTING ONE H. P. ONE MILE.

7.000														0.10	0.054	0.036
8.000															0.08	0.046
9.000																0.008

In using the table it will be convenient to draw curves of equal cost. They will be, roughly, arcs of circles convex toward the left.

The actual cost of repairs to-day on steam locomotives is, on the P. R. R. nearly 0.75 cent per h. p. hour, as will later appear. Reducing as above, this figure becomes 0.22 cent for electric traction. This refers to engines of considerable power; say from 400 to 1,000 h. p. capacity. The figure for both steam and electric motors would go up for smaller powers.

The interest charge results from considering the cost of an electric locomotive as $50 per h. p. and the duty as six hours per day full capacity. The average duty of steam locomotives is only about three hours. The higher figure results from a smaller number of repairs necessary, due to greater simplicity of parts. Then

$$\text{Interest for h. p. hour} = \frac{50.00 \times 0{\cdot}05}{365 \times 6} = 0{\cdot}11 \text{ cent.}$$

Before summarizing we must know something of the efficiency of the system. If the locomotive be of 90 per cent., or 80 per cent., or 60 per cent. efficiency, we must generate, respectively, 1.25, 1.4 and 1.85 h. p. hour in the station for every h. p. hour actually delivered to drivers, line loss being supposed constant at 10 per cent. We should then have in the station 1.56, 1.75 and 2.30 cents, respectively.

TABLE V.

Ratios of cost of motive power.

Efficiency of electric engine.	10 per cent.			20 per cent.			40 per cent.		
Tonnage and area relation.	2 & 3	2 & 5	2 & 8	2 & 3	2 & 5	2 & 8	2 & 3	2 & 5	2 & 8
Speed.									
20	1.15	1.16	1.16	0.92	0.85	0.85	0.56	0.56	0.55

60	1.25	1.24	1.19	1.00	1.00	0.95	0.58	0.58	0.56
80	1.33	1.32	1.22	1.07	1.03	0.94	0.50	0.59	0.57
100	1.58	1.42	1.32	1.23	1.20	1.05	0.66	0.65	0.59
120	2.57	1.94	1.47	1.66	1.49	1.13	0.80	0.78	0.64
140	10.03	3.82	1.87	7.35	2.83	1.46	2.72	1.36	0.72

Then, for total:

Station.	1.56	1.75	2.30
Conductor system.......	0.042	0.04	0.04
Structure for same......	0.09	0.09	0.09
Wages....................	0.14	0.14	0.14
Repairs..................	0.22	0.22	0.22
Interest..................	0.11	0.11	0.11
Total.......	2.16	2.35	2.80

Of the whole amount, it is to be noted that the station item is three-fourths. Taking the most favorable case shown by the table,—3,000 h. p. capacity, working for 24 hours at 100 per cent. of capacity—these figures become 1.5, 1.62 and 2.00 cents nearly, the reductions in the other items being still a little indefinite, without making another series of independent assumptions.

The cost of one h. p. hour, excited by steam locomotives, is to be obtained only by some circumlocution, the reports of cost being based on train-mile. As quoted by Wellington, the coal consumed per passenger train-mile on the Pennsylvania Railroad, is very closely 50 pounds, and an average performance will show 5 pounds coal per h. p. hour, while *under way*. This shows that one train-mile equals 10 h. p. hours. The coal consumption for a freight train-mile is much higher, but the divisor would also be higher, on account of the greater number of stops, or at least of backing and switching, and greater delays while on a trip, thus increasing waste of coal.

Again, the Pennsylvania Railroad reports show cost of fuel per train-mile of 5 cents. The cost of coal to that company, as nearly as I can learn, is about $1.50 per ton. Hence it would appear that 66 pounds per train-mile are consumed. As the terminal losses of fuel and delay (getting up steam and drawing fires, etc.), are known to be in the neighborhood of 25 per cent. of the total consumption, we have 6.6 (pounds) as the divisor, and the same ratio again appears.

The cost of one train-mile—as to motor power alone—is given by the Pennsylvania Railroad as 22 cents. And this is practically equal to the average for the United States. The itemized statement is very carefully made up, and seems to cover everything except interest on the engine investment.

Knowing the annual mileage per locomotive to be about 20,000 and the cost to be $10,000, interest charge per train-mile (not quite, but nearly, equivalent to engine mile) becomes 2.7 cents. Total cost becomes 24.7 cents, or 2.47 cents per h. p. hour, efficiency being constant at 100 per cent.

We may safely use this figure in the comparison to be made, since any positive error in the calculation of coal per h. p. hour, or negative error in h. p. hours per train-mile, will be offset by the difference in cost of coal per ton to the P. R. R. as compared with the value assumed in Table III.

At $3, instead of $1.50, the full item would be 10 cents and the total motive power 29.5 cents. Leaving the statistics of actual cost, we may reach, by the method of Table III., nearly the same figure, considering the locomotive as a 1,000 h. p. steam plant, of low first cost, burning 6 lbs. of coal per h. p. hour, and working at one-third capacity for about three hours per day. The result thus reached is about 10 per cent. higher, but the 2.47 cents seems most reliable.

These values multiplied into the corresponding values in the last nine columns of Table I., give the following values of:

$$\frac{\text{Power units, steam}}{\text{Power units, electric}} \times \frac{\text{cost per unit, steam.}}{\text{cost per unit, electric.}}$$

This value, Table V., being greater than unity indicates greater economy by electricity than by steam, and vice versa.

A glance at the table shows the dominating necessity of increasing the efficiency of the mechanism delivering energy from the electric line to the vehicle. We cannot count upon a higher efficiency than 90 per cent. for the motor. Hence, save in the case of putting the armature directly on the axle, we cannot hope to reduce the total loss to less than 20 per cent.—a case permitting one set (*i. e.*, two gears) of spur gearing between armature and axle. As the ordinary relation between tonnage and resisting area will lie between the second and third columns of each efficiency table, it appears that with a 20 per cent. loss electricity becomes cheaper than steam at about 70 miles per hour.

In the case of 40 per cent. loss our new agent betters the old only at 140 miles per hour. And yet this loss—40 per cent.—is about the best we do with our present systems of electric propulsion. This appears from the following tabulation of results obtained by me on the Brooklyn & Jamaica Electric Railway, Table VI.

Considering the very short life of the art, these results are excellent. Indeed, excellence is shown in the mere fact of success in competing with horses under conditions very trying for any mechanism not made of india-rubber or whit-leather. How great that success has been I need not here proclaim. But the steam locomotive is a foeman more worthy of our steel, or rather of our annealed soft iron, and 99 per cent. copper.

Consideration of all that precedes leads to the following general conclusions:

1. A slow-speed armature placed on the car axle would place the electric motor in the lead at all service speeds.

2. For speeds above 70 miles per hour an electric motor of 90 per cent. efficiency, working through gearing of 90 per cent. efficiency would prove more economical than the steam locomotive—save in cases of very infrequent service on very long lines.

3. On lines for heavy traffic steam would be more economical than electricity if motor and gearing have a combined efficiency as low as 60 per cent., up to 100 miles per hour.

4. At speeds of 100 miles per hour and upward, neither steam at 90 per cent. nor electric apparatus at 60 per cent. efficiency is commercially practicable.

5. Inasmuch as the saving of coal in stationary, as compared with locomotive engines, is one of the chief causes of the greater economy of electric propulsion, at any speed, this advantage will increase with that difference and also with the price of coal.

6. Any cause other than inefficiency of motor which increases the power required to haul a ton of freight, increases the advantages of electricity, since it enlarges the value of the coal difference and the dead-weight difference.

Thus bad roadways and large areas exposed to atmospheric resistance, as in street railway work, lower the speed at which electric motors of any efficiency become cheaper than steam.

7. In descending to small locomotive units, the electric motor loses less, relatively, of its advantage—another reason for success on street lines.

8. Multiplying the number of motors should be, as far as possible, avoided.

9. In special cases cleanliness and compactness of electric machinery may be of great value; in case of very frequent stops, the possibility of returning to the line the energy now wasted in brakes may be of considerable value. This, however, can be obtained only by sacrifice in the matter of dead-weight, as normal working is implied to be at comparatively low magnetization. Loss due to low efficiency in starting can scarcely be avoided either in steam or electric engines.

10. Other minor pros and cons may be enumerated, but I believe that in considering the general economic results of the two systems we reach more definite conclusions.

While only one condition of station working has been taken for final comparison, that case is an average one, and comparative results would be but slightly affected by ordinary variations. Extreme cases may be readily determined from the tables and formulas presented.

11. Some differences of opinion as to the proper values for the various constants are to be expected, but I believe these differences, taken all along the line, would nearly balance between positives and negatives, leaving the general results and the method unchanged.

THE NATIONAL WATER WORKS ASSOCIATION held their convention in Chicago at the Grand Pacific Hotel, May 20, 21, 22. The electric light companies subscribed very liberally to a fund for the entertainment of the association.

TABLE VI.

NOTE.—Voltmeter readings taken April 3, and 20, assumed same values May 2. Traction coefficient also taken from April 20, as track was in same condition. Losses in motors cannot be given with perfect accuracy, as they have not been determined for wide ranges of condition by shop tests. Values for hysteresis, etc., here taken correspond closely with several shop tests. Except $C^2 R$, motor loss does not vary largely with current flowing in practice, as with a low current, a very large armature induction is effected. The "R" in $C^2 R$ cannot be known accurately, as it constantly changes with change in position of switch. A fair average of switch position was obtained from observation. Total error in motor losses probably not greater than 10 per cent. Run No. 7 not introduced here for discussion of difference of action of motors "A" and "B:"

Average efficiency whole mechanism, two motors = 55.9 per cent.
" " " " one motor = 71.2 "
" " one motor alone............... = 83.6 "
" " two motors " .... = 77.6 "
" " two sets gears alone....... .. = 71.8 "
" " one set gears................... = 85.3 "

LIFE AND EFFICIENCY OF ARC LIGHT CARBONS.[1]

BY LOUIS B. MARKS, M. E.

From the experimental stage of arc lighting to the commercial application of the system to-day, little or no increase in the efficiency of the carbon points appears to have been made.

Now that our dynamos and lamps have reached such a state of perfection, the subject presents itself as pre-eminently important. The arc light pencil, considered as an individual part of the plant, is indeed a small thing, but in it undoubtedly lies the weak spot of the system.

It was with a view of studying the action of modern carbon pencils, that the investigations here to be described were undertaken. The carbons experimented upon were all of American manufacture, and were procured from five companies, (A, B, C, D and E)

While the greater part of the research was upon the life and efficiency of the pencils, observations were also made in other directions.

The subject will be treated under the following heads:—

1st. Structure of the carbons.
2d. Life tests.
3d. Efficiencies.
4th. Candle-power measurements.
5th. Observations of the arc and carbon points.

It is well known that the life and efficiency of a carbon depends upon the system in which the latter is burned. For instance, "the requirement of the low tension system seems to be a carbon that is hard, well plated and a good conductor, the latter being the most important."

"In the high tension system, on the contrary, hardness and conductivity seem to be of secondary importance. There is a tendency to 'flame' and burn unsteadily when a hard carbon is used in this system, and a softer one sometimes becomes necessary.[2]"

It is interesting to note the methods employed by carbon manufacturers to attain the conditions above mentioned. In one of our largest carbon works, "forced" carbons, or those made by "squirting" the plastic material through a die, are manufactured for both high and low tension systems of lighting, to the exclusion of molded pencils. On the other hand, another company makes no forced carbons, but claims that its molded pencils are superior for either system. From the classification given below, can be seen the types of carbons now upon the market for both systems.

One of the first things that suggested itself was the study of the structure of the various samples submitted.

Carbon.	High tension.	Low tension.
A	molded	forced
B	"	molded
C	"	"
D	forced	forced
E	molded forced	"

For this purpose, thin transverse sections of all the specimens were cut and mounted on glass slides, and a microscopical examination made.

The accompanying photographs (Figs. 1–12) show the appearance of the carbons under a magnifying power of about forty diameters in the case of groups A, B and C, and about eighty diameters in that of D and E. While the views cannot give either the color or lustre of the original, they are mainly useful in con-

Arc Light Carbons Under the Microscope.

---

[1] Read before the General Meeting of the American Institute of Electrical Engineers, Boston, May 21st, 1890.

[2] G. W. Parker: Proceedings National Elec. Light Assoc'n, Pittsburgh Convention, Feb., 1888, p. 455.

veying an idea of the texture of the surface.

Examining the photographs, we note that there is a marked difference between the structure of a molded and a forced carbon. In the high tension pencil of the brand A, (Fig. 1) the structure is a loose one, while the low tension rod of the same group is marked by a dense homogeneous structure; the size of the grains of carbon in the latter case is very much less than in the former, and as seen under the magnifying power of the microscope, the particles have a more metalloid lustre. Again there is probably considerable air space in Fig. 1.

Thus it appears that Fig. 1 has the qualifications of a high tension carbon, *i. e.* looseness of structure, hence comparative softness and high resistance; and Fig. 2 the requisites of a low tension pencil, *i. e.* density, hardness and low resistance. The resistance of the rod (Fig. 1) was measured and found equal to .199 ohm; that of Fig. 2 equalled .144 ohm. The resistance of the plated low tension carbon was .084 ohm.

The structure of the carbons in group B (Figs. 3 and 4) was found after close examination to be about the same. To secure the requisite low resistance of Fig. 4 the pencil was heavily copper-plated, the thickness of the coating being about 1-10 millimetre, while that of Fig. 3 was a little less than 1-20 millimetre.

A method different than either of those just described is used in the manufacture of carbons C, (Figs. 5 and 6.) As in the previous instance, molded carbons are made by this company for both high and low tension systems, but a much greater pressure is applied to the molds in manufacturing low tension pencils than in the case of high. This accounts for the difference in structure exhibited in the photographs; although a molded carbon, Fig. 6 thus approaches the structure of the forced pencil, Fig. 2.

Groups D and E are highly magnified. An attempt has been made to manufacture a carbon that will burn fairly well in either system. Fig. 8 shows this carbon. In structure it is a mean between Fig. 7 and Fig. 9. Besides a difference in pressure used in constructing pencils of group D, there is also a difference in the "mix" or composition of the carbon.

The dissimilarity in structure between carbon E, Fig. 11 and E, Fig. 12 is apparent, yet both pencils are used in high tension systems. The efficiency of these types, as well as of the others will be discussed later. Fig. 12, it will be noted, is very similar in structure to Fig. 9 (carbon D); in both cases the striations are marked and indicate that the carbon is built up of strata lying longitudinally, or in the same direction as the application of the pressure used in manufacturing the pencils. When examined with the microscope, carbon D, (Fig. 9) evinced more lustre than Fig. 12, showing that a greater quantity of pure carbon was used in the manufacture of the former.

LIFE TESTS.

If a carbon is burned with a small current its life will be long at a sacrifice of light-giving properties. If on the other hand a large current is used, there may be a gain in efficiency at a sacrifice of life. The question arises—what is the proper current to use? Of course circumstances determine to a large extent the answer and generally such a current is used as gives a fair mortality at a reasonable efficiency of the carbon.

The high tension carbons submitted for test were designed to be burned at about 10 amperes and the low tension at about 20. In the life tests a Thomson lamp was used for high tension runs, current being kept constant at 10 amperes and P. D. at 50 volts. For low tension carbons the Weston lamp was used. The pencils were accurately weighed before and after the runs, and the life calculated on the assumption that the carbons were homogeneous. Each set of pencils were burned an hour. The results of tests are given in Table 1.

TABLE 1.

Life Tests.

E forced low ten. (naked)....	.505	.2207	344.68	244.64	22.5	28	193.18	74.42	7.71[3]
E molded high ten. (naked)..	.533	.202	63.30	30.48	10.	50	6.09	3.04	10.39
E forced low ten. (naked)....	.522	.251	59.62	29.81	10.	50	5.91	3.52	10.09

It has been stated that "with carbons of the same *hardness* and length but having different diameters, the larger will undoubtedly outlive the smaller. Of carbons of the same *diameter* and length, but differing in hardness, the harder will outlive the softer."[4]

This statement presupposes that the conductivity of the carbon is directly dependent on the hardness or softness of the pencil.

In order to examine more fully the relation between diameter, resistance and mortality of a pencil, six sets of carbons of the brand B., varying in diameter from ½ to 1¼ inch were carefully weighed, their resistances measured by the Wheatstone bridge method and the pencils burned with a constant current of 10 amperes from a Gramme dynamo, the P. D. at the terminals of the lamp being kept at 50 volts. The diameters and resistances respectively of the upper and lower carbons were in each case practically the same. A mean of 10 micrometer measurements of the diameter, was taken as correct. The duration of each run was 60 minutes.

Following are the data:—

TABLE 2.

Mortality with Different Diameters.

CARBON.	Mean diameter; inches.	Resis. ohms.	Initial wt. + grms.	Loss wt. + grms.	Life 12 inch + carbon hours.
B molded high ten.	.453	.0805	44.70	4.20	10.64
" "	.505	.075	58.17	4.80	12.12
" "	.618	.0735	94.93	6.96	13.64
" "	.739	.0615	182.34	6.19	21.88
" "	.986	.061	282.20	8.88	26.15
" "	1.195	.059	339.57	10.14	33.49

From the results given in Table 2, it appears that the life of a carbon varies *directly* with its *diameter* and *inversely* with its *resistance*. This law holds only for homogeneous carbons of the same manufacture, type and structure, and as stated before, for constant current and voltage.

Let us take the ½ inch (.505") and 1 inch (.986") pencils as standards and from the relation above stated, calculate the mortality of the other carbons.

Table 3, gives a comparison of the actual and the calculated life of the various specimens tested.

TABLE 3.

CARBON.	Mean Diam. inches.	Standard ½" (505")	Standard 1" (.986")	Actual life hours.
		Calculated life hours.	Calculated life hours.	
B molded light.	.453	10.92	9.33	10.64
" "	.618	15.10	13.62	13.64
" "	.739	21.58	19.44	21.88
" "	1.195	36.40	33.04	33.49

Thus it appears that the calculated life throughout the series is larger than the actual when the ½" carbon is taken as a standard and smaller when the 1" pencil is made the basis of calculation.

The carbons of group B were not perfectly round, a variation of 3% being at times found, between the 10 measurements of the diameter of a pencil. In determining the resistance of the carbon rods, the tips of the latter were copper-plated when necessary and mercurial contacts used. The lamp was adjusted to burn at 50 volts potential difference for each set of pencils.

While every precaution was taken to avoid discrepancies, it is clear that from the nature of the substance experimented upon, and the extreme difficulty of maintaining constant conditions, errors are apt to creep into the work. But the results given in Table 3, as well as later determinations undoubtedly point to the existence of such a law as has been quoted.

The relation between diameter and life having been investigated, experiments were then made to determine the curve for current and mortality of the pencil, when the voltage is kept constant.

For this purpose a number of molded high tension carbons of the brand E were used. To secure uniformity in the plus and minus pencils, a 12 inch stick was broken in half, one portion being used as the upper, the other as the lower carbon. The length of each run was an hour. Current and potential were read every two minutes and the mean taken.

Table 4 gives the data from which the curve for current and mortality (Fig. 3) was plotted.

---

[3] These low tension runs were made with the Weston plant on the University Campus. Ten lamps were run in series. Time of test was 2¼ hours in the case of carbons B and E, and 2 hours and 25 min. in the case of C.

[4] G. W. Parker.

TABLE 4.

Life with Different Currents and Constant Potential.

CARBON.	Diam. mean inches.	Resis. ohms.	Initial wt.+ grms.	Initial wt.— grms.	C. amp.	P. D. volts.	Loss wt.+ grms.	Loss wt.— grms.	Life per inch. Carbon burned hours.	$\left\{\frac{\text{Life}-}{\text{Life}+}\right\}$
E molded high ten.	.518	.199	30 20	21.15	6.02	49.3	4.48	2.76	.6723	1.62
" "	"	"	25.72	18.38	7.04	49.7	4.87	3.19	.6047	1.54
" "	"	"	20.85	15.19	8.01	49.9	5.42	3.25	.5622	1.66
" "	"	"	37.56	24.16	8.99	49.9	5.81	3.63	.5450	1.60
" "	"	"	31.75	20.53	10.01	49.3	6.16	3.98	.5072	1.52
" "	"	"	30.52	21.72	11.00	50.2	6.67	4.18	.4910	1.60
" "	"	"	34.30	26.90	12.03	50.3	6.65	4.35	.4637	1.52
" "	"	"	37.78	26 33	13.00	50.1	7.[illegible]6	4.61	.4502	1.57

As will be seen the range of current was from 6 to 13 amperes. The greatest variation of the mean E. M. F. for the several runs was one volt.

TABLE 5.

Life with Different Potentials and Constant Current.

" "	.521	.517	.197	37.65	24.16	10	45	5.605	2.87	.6077	1.958
" "	.531	.522	.185	24.86	19.06	10	50	5.83	3.49	.5453	1.693
" "	.531	.522	.185	24.86	19.06	10	55	6.34	4.025	.4903	1.589
" "	.527	.530	.191	23.52	19.34	10	60	6.70	4.41	.4525	1.484

A series of tests was now made with constant current and varying voltage. The current in this case was maintained at ten amperes, and the range in tension was from forty to sixty volts. Carbons of the same type as in the last instance were used. In Table 5, are given the figures for these runs, and Fig. 14 shows the curve for voltage and mortality.

In the curves (Figs. 13 and 14) the ordinates represent the life of an inch of carbon in minutes. Reference is made not to the mortality of the plus pencil, but to the total amount of carbon burned in the lamp. The last two columns in Table 5, have been corrected for diameter and resistance of the pencil, the diameter and resistance respectively of the carbon that was burned at 10 amperes and 45 volts having been taken as a standard, and the life of the other pencils reduced to a common basis from this, according to the law previously stated.

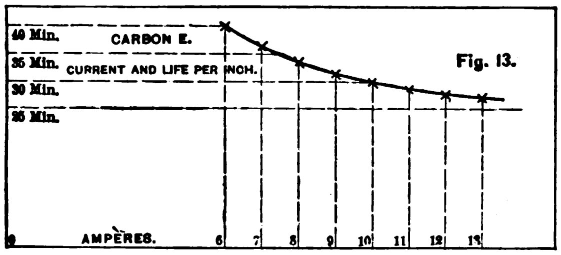

FIG. 13.

Very little has been published regarding the relative life of the plus and minus carbons. Those books in which the subject is alluded to, state as a rule that with direct currents, the life of the upper carbon is about half that of the lower, provided both have the same length originally. In a recent publication[5] the general statement is made that "with continuous currents the plus wastes twice as fast as the minus carbon. With alternating currents the upper wastes 8 per cent. faster than the lower if the carbons are vertical; but at the same rate if horizontal."

TABLE 6.

Relative Life of the Plus and Minus Carbons.

CARBON.	Initial wt.+ grms.	Initial wt.— grms.	C. ampere.	P.D. volts.	Length run; minutes.	Loss wt.+ grms.	Loss wt.— grms.	$\left\{\frac{\text{Life 1''}-}{\text{Life 1''}+}\right\}$
B molded high ten.......	48.38	25.22	10	50	60	5.28	4.40	1.20
B " low ten........	61.43	31.87	10	50	60	5.14	3.27	1.57
A " high ten.......	90.57	38.68	10	50	60	5.98	3.20	1 87
10 E forced low ten......	344.68	244.64	22½	28	150	193.18	74.42	2.59
10 B molded low ten. ..	367.80	259.50	22½	28	150	166.60	51.50	3.23
10 C " "	591.10	294 50	22½	28	145	151.00	41.00	3.68

No experiments were made upon arc-light carbons fed by alternating currents but an investigation of the relative loss of the plus and minus pencils with direct currents gave quite interesting results. Table 6 shows that the plus carbon may burn away about as fast as the minus, or may waste more than three and a half times as quickly.

Three sets of experiments were undertaken to determine the elements that effect this ratio.

FIRST. Effect of changing the diameter and resistance of the pencils with constant current and potential.

SECOND. Influence of change of current with constant potential.

THIRD. Change of potential with constant current.

For determining the influence of diameter and resistance upon the relative life of the plus and minus carbons, a number of molded high tention pencils of the brand A were used. The carbons were supposed to have been taken from the same "batch" and were burned with a current of 10 amperes and a P. D.=50 volts.

Examining Table 7, which gives the results of measurements we note that $\left\{\frac{\text{life}-}{\text{life}+}\right\}$ appears to become greater with increase of diameter of the carbon. It is probable that the inequality in the diameters of the + and — pencils respectively, as well as the difference in the resistances of the two carbons of a set explains to a large extent the cause of this increase in the ratio. For, assuming that under the conditions maintained, the life of a carbon varies directly with its diameter and inversely with its resistance, the data, (Table 7), indicate that if the diameters and resistances, respectively, of the + and — carbons were the same in each run, the ratio would be practically the same for all sizes of carbons. This is brought out in the last column of the table, which gives the corrected values of $\left\{\frac{\text{life}-}{\text{life}+}\right\}$.

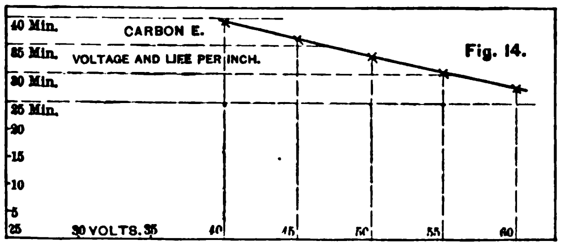

FIG. 14.

SECOND. Reference to the last column of Table 4 will show that a change in the current, other conditions remaining the same, probably has no effect on the ratio $\left\{\frac{\text{life}-}{\text{life}+}\right\}$. For when a current of 6 amperes was used, the ratio was equal to 1.62; at 7 amperes the ratio dropped to 1.54; it then alternately increased and decreased to thirteen amperes. Hence it may be said that if all errors of observation, as well as those due to irregularities in the carbons could be eliminated, the $\frac{\text{life}-\text{carbon}}{\text{life}+\text{carbon}}$ would be found to be constant.

TABLE 7.

Influence of Diameter and Resistance of the Carbon upon the Relative Life of the + and — Pencils.

CARBON.	Mean diam. inches. +	Mean diam. inches. —	Resis. ohms. +	Resis. ohms. —	Initial wt. +	Initial wt. —	Loss wt. +	Loss wt. —	$\left\{\frac{\text{Life 1''}-}{\text{Life 1''}+}\right\}$	$\frac{\text{Life 1''}-}{\text{Life 1''}+}$ corrected.
A, molded high ten.	.3964	.4 83	.255	.24	37.91	16.97	4 96	3.04	1.63	1.79
"	.4567	.4567	.225	.243	48.98	20.26	5.41	3.2	1.65	1.78
"	.5018	.5153	.199	.207	59.87	25.10	5.86	3.59	1.63	1.74
"	.5698	.5622	.178	.120	69.83	26.91	6.23	3.61	1.73	1.81
"	.6311	.6263	.152	.149	90.57	38.68	5.98	3.20	1.87	1 83

THIRD. The last column of Table 5 contains the data for $\frac{\text{life}-}{\text{life}+}$ with different P. D.'s and constant current. From these calculations it appears that the ratio depends on the P. D. and that the greater the P. D., the more nearly does the former approach unity. The curve plotted from the figures in Table 5, is given in Fig. 15, the abscissæ being volts, and the ordinates representing the ratio of the life of the minus to the life of the plus carbon.

---

[5] Munro & Jamieson's Electrical Rules and Tables, 1889.

Thus the causes that influence the relative life of pencils of the same diameter, lie chiefly in the difference in the resistance of the carbons and the variations of P. D.

Judging from existing theories of the arc, it was thought that blowing the latter with a magnet during the runs would relatively increase the life of the plus carbon. The experiment was tried and the reverse was found to take place, *i. e*, the ratio $\left\{\frac{\text{life}-}{\text{life}+}\right\}$ increased while the life of the minus pencil was not much affected.

EFFICIENCIES.

Two methods of determining the efficiency of each set of pencils were employed. The first was the method used by Mr. Merritt in obtaining the efficiency of the incandescent lamp[6] and subsequently by Mr. Nakano in his work on the efficiency of the arc-lamp[7]. The second dealt with candle-powers and will be referred to in the discussion of candle-power measurements.

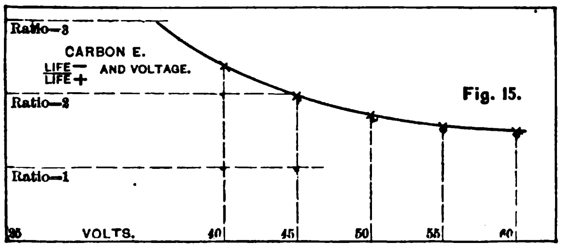

FIG. 15.

It may not be amiss to give here an outline of the first method employed. A Thomson lamp was mounted on a movable frame and the rays from the burning carbons allowed to fall on the face of a thermo-pile, the latter being in circuit with a sensitive Thomson galvanometer. The deflection of the galvanometer was taken as a measure of the energy of the total radiation which fell upon the face of the pile. A cell containing a solution of alum was then interposed between the light and the pile, and the reduced deflection of the galvanometer noted. On the supposition that the alum cell cut off all the "dark heat" and allowed only the rays of the visible spectrum to reach the face of the thermo-pile, the last measurement would give the true value of the luminous energy emitted by the lamp. But a small percentage of the longer wave lengths passes through the alum cell, and a large part of the luminous rays is cut off by its intervention. Corrections having been made for these factors, the true values of luminous radiation resulted.

A mechanism was provided by which measurements could be made at various angles below the horizontal plane without altering the distance between the center of the arc and the thermo-pile.

For the high tension runs, the lamp was fed by a current of 9 amperes, the potential difference between its terminals being kept at 45 volts. For low tension tests, current=21½ amperes, and P. D.=30 volts. Note that the amount of energy expended in the low tension lamp was 21½ × 30 = 645 watts, while the high tension required but 9 × 45 = 405 watts. Although normally the former requires from 520 to 560 watts, unsteadiness of the light when the lamp was run below 21½ amperes made accurate measurements impossible.

Tables 8—15 give the results of efficiency tests. In the column headed (L) are given the corrected values of deflections due to luminous radiation; the values of (T) refer to total radiation and the efficiency or luminous divided by total radiation $= \left\{\frac{L}{T}\right\}$.

These tables furnish the data from which the curves (Figs. 16-23 were plotted. The radii show the positions for which measurements were taken, and distances measured along these lines from the origin to the *dotted* curves give the intensity of luminous and total radiation, respectively in each position.

It will be seen that the distribution of total radiation differs considerably from that of luminous radiation, hence the efficency, which is expressed by $\left\{\frac{\text{luminous radiation}}{\text{total radiation}}\right\}$ depends upon the angle of measurement.

The full-line curves (Figs. 16-23) represent the efficiencies of the various carbons. In order to obtain the mean or hemispherical efficiency, the areas of the curves of luminous and of total radiation were found by means of the planimeter; now the ratio of the radii of two semi-circles whose areas are respectively equal to those of the curves of luminous and total radiation, is the value of the mean spherical efficiency. This value has been calculated for each set of pencils and the results are given in Table 16; also in Figs. 16-23.

A forced low ten.............	.500	.072	21.5	30	.0542	.1351	.1105	10.85	[illegible]
B molded low ten............	.498	.071	21.5	30	.0569	.1273	.0932	9.43	[illegible]

We notice that the horizontal efficiency is very small compared with the maximum; that relatively high efficiency in a *forced high tension* carbon is obtained only at the expense of life; that a *molded* carbon is, generally speaking, superior to a *forced* for high tension and vice versa for low tension.

In the case of the high tension carbon B and D, the diameters are smaller than those of the other pencils, hence we are to expect a relatively higher efficiency, since as was shown last year the efficiency varies inversely as the diameter."[8]

[6] E. G. Merritt: Some Determinations of the Energy of the Light from Incandescent Lamps. *Amer. Jour. Science.* Vol. 37. p. 167.

[7] H. Nakano: Efficiency of the Arc Lamp; Transactions Amer. Inst. Elec. Eng. Vol. VI, p. 308.

A point of interest brought out by these tests (Tables 10 and 11 and Figs. 18 and 19), is the fact that while the life of a copper-plated carbon is greater than that of an unplated carbon of the same diameter and type, the mean spherical efficiency appears to be the same for both.

Two sets of pencils of the brand (B), the one unplated and the other plated, were burned to ascertain this relation. The results show that the horizontal and the maximum efficiency of the copper-plated carbons were a little greater than those of the uncoated pencils respectively, and the mean spherical efficiency in the latter case was very slightly less than in the former. As can be seen from Table 16, the life of the "positive" plated pencil (12" long) was 10.64 hours, while that of the naked carbon was 9.16 hours, the current and P. D. having been the same for both cases.

MOLDED
HIGH TENSION
SPHER. EFFIC.
= 12.69%

No positive explanation of this phenomenon has yet been given, but it appears that the actual amount of *combustion* in both cases is the same, while the *disintegration* caused by the passage of the current is greater in the case of the unplated carbon.

CANDLE POWER MEASUREMENTS.

The candle-power measurements consisted chiefly in the determination of the hemispherical candle-power of the different pencils, and from this quantity the watts per spherical candle-power produced.

The runs were made under the same conditions as in the efficiency tests. For high tension carbons current = 9 amperes and P. D. = 45 volts. For low tension pencils, current = 21.5 amperes and P. D. = 30 volts.

To ascertain the candle-powers, the method of the Franklin Institute Committee was used.[9] The photometric apparatus was somewhat different in detail from that ordinarily used in measuring the candle-power of incandescent lamps and deserves a brief description.

The arc-lamp was suspended from an arm which could be rotated about an axis parallel to the photometer bar and vertically above it. By manipulating a rope connected with the arm, the latter could be raised until it was at right angles with the photometer-bar, or lowered until it was horizontal. The arm being horizontal, the lamp was hung from its extremity so that the arc was on a level with the center of the photometer-disc. It will be seen that when the arm was pulled up, the arc described a vertical circle, the axis of which was a line parallel to the photometer-bar and passing through the center of the disc. The centre of the vertical circle was at the point (800) of a scale graduated into (1,000) divisions, and the radius equal to the length of 200 scale divisions.

At the zero of the scale was placed a Weston incandescent lamp, and a circular mirror of silvered glass, the axis of which was horizontal and inclined 45° to the reflecting surface; it was mounted on the bar so that its centre coincided exactly with the 800th division of the scale. Thus the distance between the arc-lamp and the mirror was rendered constant for all elevations of the former, and when the mirror reflected the light of the lamp upon the disc, the angles of incidence and reflection were always equal to 45°. The virtual image of the arc under these circumstances was at the 1,000th division of the scale. The Weston lamp was used as a secondary standard and maintained by a storage battery throughout the runs at 115 volts; its candle-power was ascertained before and after the tests by comparing it with a standard Methven "Board of Trade" 2 c. p. slit.

Photometer readings were made as in the case of the efficiency tests, at 0° and at 10°, 20°, 30°, 40°, 50°, and 60°, below the horizontal, the mean of twenty observations being taken for each elevation. These measurements were multiplied by the candle-power of the secondary standard and corrected for absorption of light by the mirror.

Tables 17-23 give the corrected data, which form the basis of the candle-power curves (Figs. 24 and 25). Distance measured along the radii from the origin to each curve, give the candle-power for the various angles. The mean spherical candle power for any case is measured by the radius of a semi-circle whose arc is equal to the area of the c. p. curve.

Although great care was taken in ascertaining the candle-powers, the difference in color between the light emitted by the arc and that given by the standard was so marked that the setting of the photometer-carriage was to a large extent a matter of personal judgment; hence the measurements given cannot be considered as absolute, but rather as relative values.

The conclusions drawn from the efficiency curves hold generally, as will be seen by an examination of Table 24, for the candle-power curves. From the latter it appears that the efficiency of low tension carbons, and especially of *molded* low tension pencils, is comparatively small. While the efficiencies of molded high tension carbons are as high as .953 and .888 watt per spherical candle, or 783 and 840 candles per electrical horse-power expended in the lamp, the efficiencies of low tension pencils of nearly the same diameter as the high are as small as 1.255 and 1.612 watts per candle, or 594 and 502 candles per electrical horse-power.

This fact is not brought out in Table 16, for reference to the latter shows the low tension pencils to have a rather high efficiency, and in some cases considerably higher than the high tension carbons. However, when the energy expended in the lamp in the two cases respectively is taken into account, the explanation of the high values for carbons A and B (Table 16, low tension) is apparent.

Carbon B (molded high ten., Table 24), it will be noted has the highest efficiency of the group. This is due largely to the fact that its diameter is smaller than that of any of the others, for "the candle-power varies inversely as the diameter."[10]

Similarly the relatively high candle-power of carbon D is accounted for by the small diameter of the pencil. In Table 24 and the candle-power curves, we again note the comparatively small efficiency of *forced* high tension carbons.

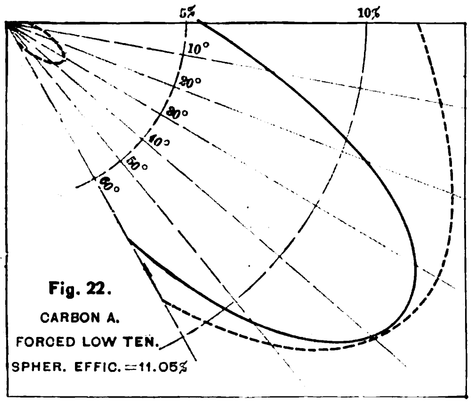

Fig. 22.
CARBON A.
FORCED LOW TEN.
SPHER. EFFIC.=11.05%

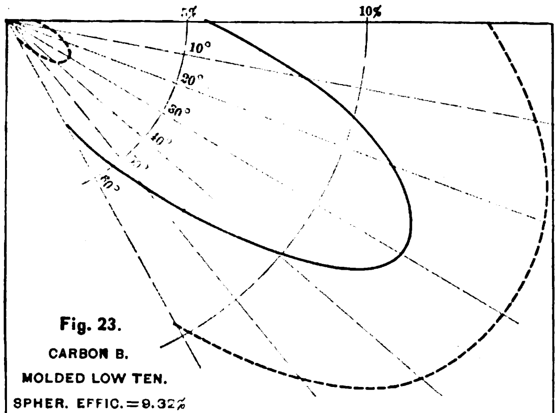

Fig. 23.
CARBON B.
MOLDED LOW TEN.
SPHER. EFFIC.=9.32%

The efficiency of carbon A (molded high tension, Table 16), as measured by $\left\{\frac{\text{luminous radiation}}{\text{total radiation}}\right\}$ is larger than that of carbon D; yet the mean spherical candle-power of the latter is greater than that of the former (Table 24). The explanation of this phenomenon (assuming the measurements to be correct) probably lies in the difference in the *quality* of the light emitted.[11]

In some instances it is desirable to ascertain the mean spherical candle-power of a lamp approximately, without taking the time to integrate the curve.

The formula given by M. Gérard, namely, "spherical c. p. = ½ horizontal c. p. + ¼ maximum c. p."[12] is of sufficient exactitude for practical purposes. Gérard gives the following table showing the observed and calculated spherical candle-powers for seven lamps.

" 6	586	2100	818	802
" 7	935	1150	755	707

Taking the whole number of lamps, the average error is only five per cent. "The angle of maximum intensity was about 45° usually, but in some cases it approached that of 30°, or 60° from the horizontal."

Data collected from various sources, including the tests of the Franklin Institute Committee in 1884, are given in Table 26. From the horizontal and maximum candle-powers, the mean spherical was calculated by Gérard's law. Comparison with the observed candle-powers shows that in some cases the error is less than one per cent. The mean error is, however, larger than that obtained by Gérard, and reaches about 9¾ per cent. Hence, as was stated before, the law is valueless except in cases of rough approximation.

Reference has been made to the fact that while the curve for luminous radiation is similar to that of candle-power, the curve for total radiation differs widely from the latter. As the efficiency depends upon the ratio $\left\{\frac{\text{luminous radiation}}{\text{total radiation}}\right\}$ it is plain that Gérard's law will not hold for calculating the mean spherical efficiency from the horizontal and the maximum. But again, for approximations a similar law holds, *i. e.*,

Spherical efficiency = ¼ *horizontal* + ¾ *maximum.*

Although the topic of efficiencies has been discussed in another part of the article, it may not be out of place to add a few words here, bearing upon the law in question. Measurements of horizontal, maximum and mean spherical efficiency, made by Mr. H. Nakano and by the writer, are given in Table 27, and the last law mentioned applied in the calculation of the spherical efficiency. In some cases the error is exceedingly small while in others it is comparatively large; the mean error of 14 tests is not quite eight per cent.

OBSERVATIONS OF THE ARC AND THE CARBON-POINTS.

With a given potential difference between the terminals of the lamp, the length of the arc depends upon the current flowing, and increased as the current becomes greater. If the current be kept constant, the length of the arc increases with the P. D.

Data given in Tables 28 and 29 show the length of the arc for both cases.

In order to measure the length of the arc, a lens was so mounted as to throw the magnified image of the former upon a surface carrying a vertical scale. Then after measuring the distance between the magnified points and applying the proper reduction factor, an additive correction was made for the depth of the crater, thus giving the length of arc from the tip of the minus pencil to the point directly above in the centre of the crater of the plus.

From the figures (Tables 28 and 29), it seems that no direct relation exists between the length of the arc and the current and P. D. In the case of the carbons tested, the length of the arc with constant potential increased very rapidly as the current was changed from 6 to 9 amperes, and then gained slowly from 9 to 13 amperes. The nature of the change was somewhat different in the constant current runs, the length of the arc increasing more nearly as the square of the voltage.

After each of the runs noted in Tables 28 and 29, the carbon-points were examined, and it was found that the latter assumed particular shapes depending upon the current and P. D. used. Another series of tests were made with carbons C. and E. (molded high ten), in which the current ranged from 5 to 15 amperes, the P. D. being kept constant at 50 volts.

Fig. 26 shows the form of the points with different currents. Nos. 1, 2 and 3 are pencils of the brand C. and 4, 5, 6 and 7 of the type E. The photographs of the carbons are three-quarters of the actual size.

Examining the first three pencils, we see that with 5 amperes, there is a tendency to form a "mushroom" on the lower or negative carbon; the latter is eaten away considerably just below the tip. With 10 amperes this tendency is not at all marked and at 15, almost inappreciable.

Glancing at the upper or plus carbons, it appears that the smaller the current, the more nearly does the positive pencil burn to a point; that is, the smaller the diameter of the crater. But though the width of the crater is less in the case of low currents than with high, the depth of the former is correspondingly greater. The photographs do not bring out this point, but an inspection of the tip of the lower carbon gives a clue to the facts. Note that with small currents the negative electrode terminates in a pointed, sometimes globular projection. As has been stated before, this tip becomes less noticeable with increase of current, a fact which is brought out by inspecting Nos. 7, 6, 5 and 4 (Fig. 26). In No. 4, burned at 15 amperes, the end of the lower carbon is blunted; the depth of the crater in the upper was practically zero. In Nos. 5, 6 and 7, burned at 12, 9 and 6 amperes respectively, the depth of the crater increases as the current diminishes.

With high currents, the carbon is disintegrated to a greater distance above the point than with low.

Fig. 27 shows the form of the carbon points when the latter are burned with constant current=10 amperes. The range in P. D. was from 40 to 60 volts.

Just as the peculiar burning of the tip distinguishes a pencil fed by a low from one burned at a high current, so the form of the carbon-point differs in the case of a pencil burned with low voltage than with high. In Nos. 1, 2, 3, 4 and 5, Fig. 27, the gradual change in the formation, from a sharp projection at 40 volts to a blunt end at 60 volts is noticeable.

The "mushroom" which invariably forms in carbons burned at a low current and high voltage, is absent when the pencils are burned at high current and low voltage.[13] In the former instance the thin neck of the "mushroom" often breaks, thus arresting the current and extinguishing the arc. In the latter case the end of the carbon is prone to so burn away as to leave a concave outline. (See No. 1, Fig. 27.)

---

[13] When the carbon is impure and contains a large amount of silica, the latter is often deposited in the form of a glass bead on the point of the negative pencil. The "mushroom" alluded to in the text does not refer to this deposition.

[14] O. G. Pritchard: Electric Arc Light Carbons. London Elec., Mar. 21st and Apr. 4th, 1890.

At 40 volts the depth of the crater measured .051 inch. At 60 volts the crater disappeared ; the carbons also "flamed" at this high voltage.

With a given current there is for every brand of carbon a certain voltage, above which, if the pencil be burned, "flaming" will result. A simple trial is sufficient to determine this critical point.[14] Again, there is a voltage below which, if the carbon be burned, "hissing" takes place. With perfectly centered carbons there is no difficulty in ascertaining the latter point.

Careful observation of the arc shows that when the tension is too high for a given carbon, the walls of the crater break away, allowing the arc to play on the outside surface of the carbon. This action is always accompanied by a flame, which shoots from the negative carbon. On placing the negative pencil above and the positive below, the flame shoots down. With soft-cored carbons, well centered, one cause of flaming,—namely, liability of the arc to play laterally,—is obviated; and if the pencils be burned with the proper current and voltage, there seems to be no reason why this disagreeable feature of the arc lamp should not be entirely overcome.

There is not so much liability to "hiss" in a high tension system as in a low, for from the formation of the carbon-points when the pencils are burned in commercial low tension lamps, it appears that the minus carbon terminates in a small mushroom-button. The breaking of this pellicle of carbon and the consequent action of the lamp-mechanism to reduce the rise in potential due to the rupture, invariably result in the "hissing" of the arc.

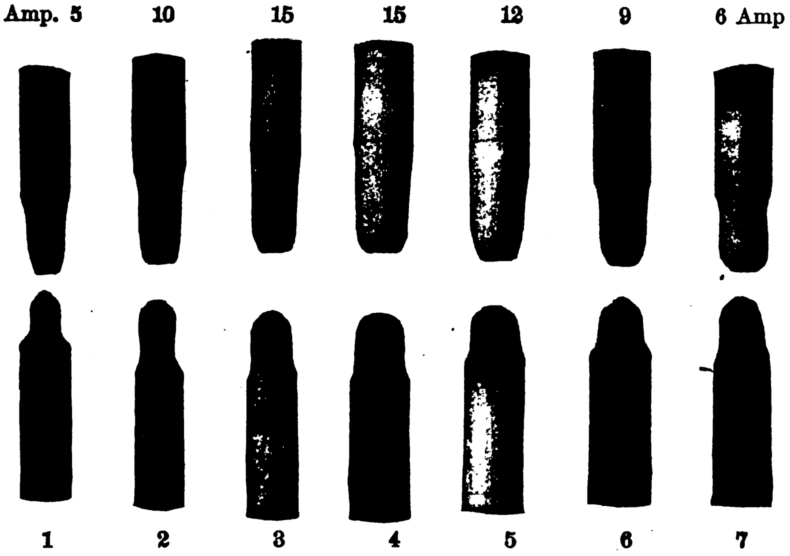

FIG. 26.

Form of the Carbon Points: Constant Potential—50 volts.

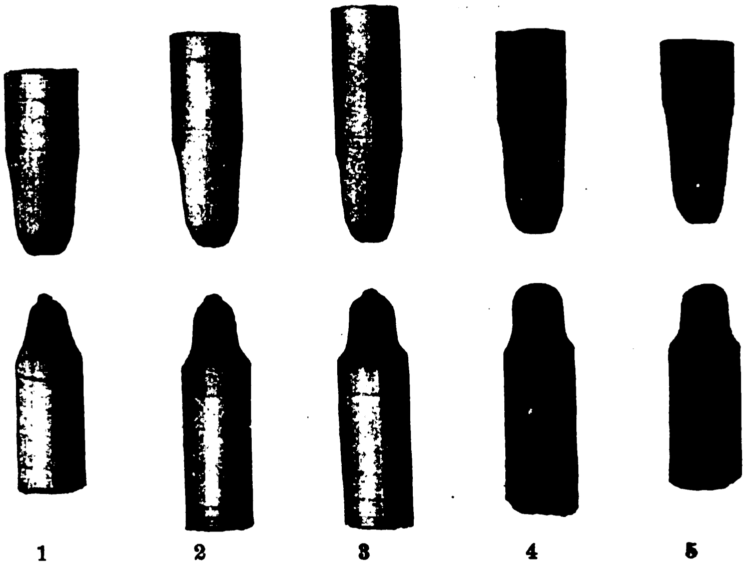

FIG. 27.

Form of the Carbon Points: Constant Current—10 Amperes.

Most of the irregularities in the action of arc-lamps probably result more from the unsuitableness of the carbon than from defects in the lamp-mechanism or changes in the strength of the current and P. D. in the line.

The remedy lies with the carbon-manufacturer. A careful study of the relation between the miscroscopical structure of the pencil and the action of the latter in a given case would be likely to bear fruitful results. Of course the field for experimentation is large, but the improvements which must necessarily follow conscientious research will undoubtedly be of great scientific as well as commercial value.

In the present state of the art of carbon-manufacture, it is the central-station manager who must exercise great discrimination in the selection of arc-light pencils for his plant. Mr. E. F. Peck has recently shown how a "comparative test of the best known carbons in the market" resulted in "a saving of 64.73 electrical horse-power in a station burning a thousand arc-lamps."[15]

But there is no reason why the carbon-manufacturer, given the condition of a lighting system as regards current, tension, required light and life of pencils, etc.—should not be able to produce a carbon specially adapted to the needs of that system.

When the root of existing defects is thus struck at, the solution of the arc-light carbon problem will be at hand.

The experiments published in this paper were made under the direction of Professor Edward L. Nichols, in the laboratory of Cornell University. The writer is indebted to Mr. A. B. Levy, P. G., for valuable assistance in the work.

NOTE ON A NEW PHOTOMETER.[1]

BY PROF. EDWARD L. NICHOLS.

Methods of photometry which take no cognizance of differences of quality are so ill adapted to the study of sources of light which differ from each other widely in temperature, that the introduction of some instrument by means of which both the character and intensity of an illuminant can be readily determined, would be a desirable adjunct to the equipment of our photometer rooms.

The instrument which it is my purpose to describe has been designed to meet this need. Existing types of the spectro-photometer may be made to give good results, but they are expensive instruments and so difficult to use that it is only in the hands of observers of considerable experience that accuracy is assured.

The new apparatus, the "horizontal-slit" photometer, is in point of fact a spectro-photometer in which the polarizing device is entirely done away with. In it the extremely simple principle of the Bunsen photometer is applied successively to the various regions of the visible spectra of the source of light which are to be compared. A direct vision spectroscope of Browning's form is attached to the usual car of a Bunsen photometer, from which the disk and mirrors have been removed. The optical axis of the collimator is horizontal and at right angles to the photometer bar. The slit is horizontal and lies in a straight line, joining the sources of light, which are set up in the usual manner at the ends of the bar. The bar itself is preferably of considerable length; in the case of the one upon which the original instrument under consideration was mounted, it was 500 c. m. long, and should be divided into 1,000 equal parts.

In front of the spectroscope slit are placed two right angled prisms of the same size and made of the same glass (see Fig. 1). Their vertical adjacent edges bisect the slit, and light traveling from either end of the photometer bar is totally reflected by them and enters the right or left hand end of the slit in a direction parallel to the optical axis of the collimator tube.

The two sets of rays thus gathered into the spectroscope from the lights at the end of the bar are vertically dispersed by the Amici prisms and appear in the field of view as two vertical spectra standing side by side. Equal wave lengths are in the same horizontal line and any desired region may be brought into the centre of the field by an angular movement of the ocular telescope. The telescope moves along the arc of a suitably divided semi-circle, to which it may be clamped by means of a set-screw. Wave lengths corresponding to the various circle settings are determined once for all, by observation of the more prominent of the Fraunhofer lines.

When the instrument, thus mounted, is placed at the middle of the photometer bar, between lamps which are identical in intensity and quality, the two spectra are of equal brightness throughout, wave length for wave length, from red to violet. If the two lamps differ in intensity but not in quality, the two spectra will differ in brightness by the same amount from end to end, and a position may be found upon the bar for which they will be identical throughout.

---

1. A paper read before the American Institute of Electrical Engineers, Boston, May 21st, 1890.

Under these circumstances, which are the only ones in which the Bunsen method in photometry is strictly applicable, the instrument may be used as a simple photometer, the setting for any wave length whatever giving the candle-power. For this purpose alone, viz., for the comparison of lights of similar character, the instrument offers certain manifest advantages over the various forms of the Bunsen photometer. In the course of the present paper I shall present some definite data concerning the relative sensitiveness of the two instruments when used in this way.

When the lights to be compared differ both in intensity and quality, ordinary photometric indications possess no perfectly definite significance. In this, which is the more general case, the relative brightness of the spectra of the two sources varies with the wave length. For each region of the visible spectrum, however, a position upon the photometer bar can be found at which the brightness of the two spectra in that region will be equal, and the observations thus obtained, when extended over the entire spectrum, will afford data by means of which the differences in quality of the two sources of light may be definitely expressed.

In a recent paper read before the Institute,[2] for a considerable range of temperature at least, the ratio between the intensities of a certain wave length of the spectrum of glowing carbon, is identical with the ratio of candle-powers as determined by the Bunsen photometer. The wave length in question, determined from the intensity of the spectrum of incandescent lamps at various candle-powers, I had found to be approximately $\lambda=600$. M. A. Crova, in an important paper since presented at the late electrical congress at Paris[3] has pointed out the importance of this method of measuring the light from sources differing in temperature. The wave length which he has indicated for this purpose is $\lambda=582$, which belongs to a region lying slightly further toward the green than the one which I had adopted.

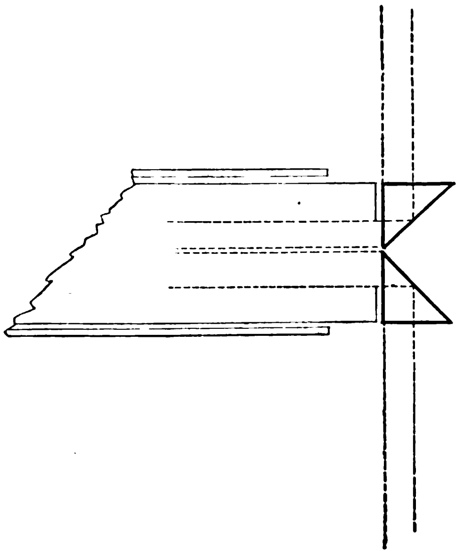

FIG. 1.—A NEW PHOTOMETER.

When the wave length of this region has been established beyond question, the photometry of lights which vary in color. will have been reduced to a definite scientific basis. Instead of attempting to use the Bunsen photometer in measurements to which it is not adapted, we shall be able to deduce the relative candle power of two sources of light from the comparison of a single wave length, and we shall be freed from the uncertainty arising from differences of color and from the personal errors due to the independent use of the two eyes in observation. The determination of candle-power will then be an operation of precision, even when the sources of light to be compared vary widely in temperature. It is in the opportunity of performing such observations upon the photometer bar itself, under conditions which do away with many of the sources of error inherent in the usual methods of spectro-photometry, that the chief advantages of the new photometer will be found to lie.

The following set of observations, taken with the new instrument, may serve to indicate one of the uses to which it may be put. The data[4] are taken from an investigation now in progress in the Physical Laboratory of Cornell University. The object in view was to compare the spectrum of a novel type of gas burner with that of an ordinary argand burner. The two lamps were set up at the ends of a photometer bar five meters long, the bar, as already stated being divided into 1,000 equal parts. Readings were taken at six points in the spectrum. The purposes being to express the relative brightness of the two spectra, wave length for wave length, the intensity of that due to the argand burner was taken as unity throughout, and the brightness of each region of the spectrum of the flame under investigation was obtained in terms of that of the corresponding region of the spectrum of the argand. The results are given in Table 1:

TABLE 1.

Comparison of the spectrum of a Welsbach burner with that of an ordinary argand burner, by means of the "horizontal-slit" photometer.[4]

Color.	Wave length	Light-ratio $\frac{\text{Welsbach}}{\text{Argand.}}$	Probable error of a single observation.
Red	702	0.709 ± .017	2.45%
Yellow	589	1.476 ± .017	1.14%
Green	558	1.760 ± .023	1.34%
	500	2.895 ± .047	1.99%
Blue	466	2.738 ± .036	1.30%
Violet	439	3.090 ± .073	2.35%
			1.76% (average

Ten observations were made in each region.

I introduce these measurements here simply as an illustration of one line of work to which the instrument under consideration is adapted. A full description of the research of which they form a part, and which covers many other questions pertaining to the very interesting class of lamps with which it deals, will doubtless be published in due time.

As will be seen from the column of probable errors, the sensitiveness of the instrument is greatest in the region of the D line (λ—589) and least in the extreme red and violet, where the light intensities are small.

A set of ten determinations made by the same observer with the Bunsen photometer, gave for the total light-ratio of the two lamps:

$$\frac{\text{Welsbach}}{\text{Argand}} — 1.701 \pm .015$$

The probable error of a single observation in this series amounted to 0.89%, a value somewhat smaller than that obtained with the new photometer in the yellow of the spectrum.

The number of observations is too small to afford a close estimate of the relative sensitiveness of the two instruments, but the results suffice to show that the "horizontal-slit" photometer does not differ appreciably in accuracy from the Bunsen photometer when the latter is used in the comparison of flames of the same color.

When it comes to the measurement of sources of light that differ widely in temperature, the comparison is decidedly in favor of the "horizontal-slit" photometer, the sensitiveness of which is not affected by differences of color. The error of the Bunsen photometer in candle-power measurement of the arc light, for instance, calculated from ten observations recently made upon the same photometer bar, the reference standard being an argand gas burner, was 2.65% (probable error of a single observation), a value more than twice as large as that of the "horizontal-slit" photometer.

A comparison of the performance of the new photometer with that of a polarizing spectro-photometer of the type which is commonly recognized as affording the highest degree of accuracy, is likewise decidedly in favor of the former. Taking as a basis eight observations made by Mr. Franklin and myself in the study of a bat's-wing gas burner,[5] the observations covering eight regions of the spectrum, I find the error of a single observation, in the various regions, to have been as follows:

TABLE 2.

Probable errors of a single observation with a polarizing spectro-photometer, calculated from sets of ten observations upon various portions of the spectrum of a gas flame.

Wave lengths.	Probable error of a single observation.
758	7.9%
668	4.9%
608	4.5%
557	5.4%
518	6.4%
492	7.0%
468	3.0%
450	2.4%
	5.2% (average.)

The measurement of a fluctuating illuminant, such as the gas-flame, is a line of investigation by no means adapted to exhibit any photometric instrument at its best; but as the errors of the horizontal-slit photometer, already given, were calculated from sets of ten observations upon such flames, I have selected for comparison similar sets of ten upon sources of the same character.

---

[2] Transactions of the American Institute of Electrical Engineers, vol. 6, p. 183.

[3] M. A. Crova, *La Lumière Electrique*, vol. 33, p. 478.

[4] From observations by Miss Ida M. Hill.

[5] American Journal of Science, vol. 38, p. 100. See also Transactions of American Institute of Electrical Engineers, vol. 6, p. 177.

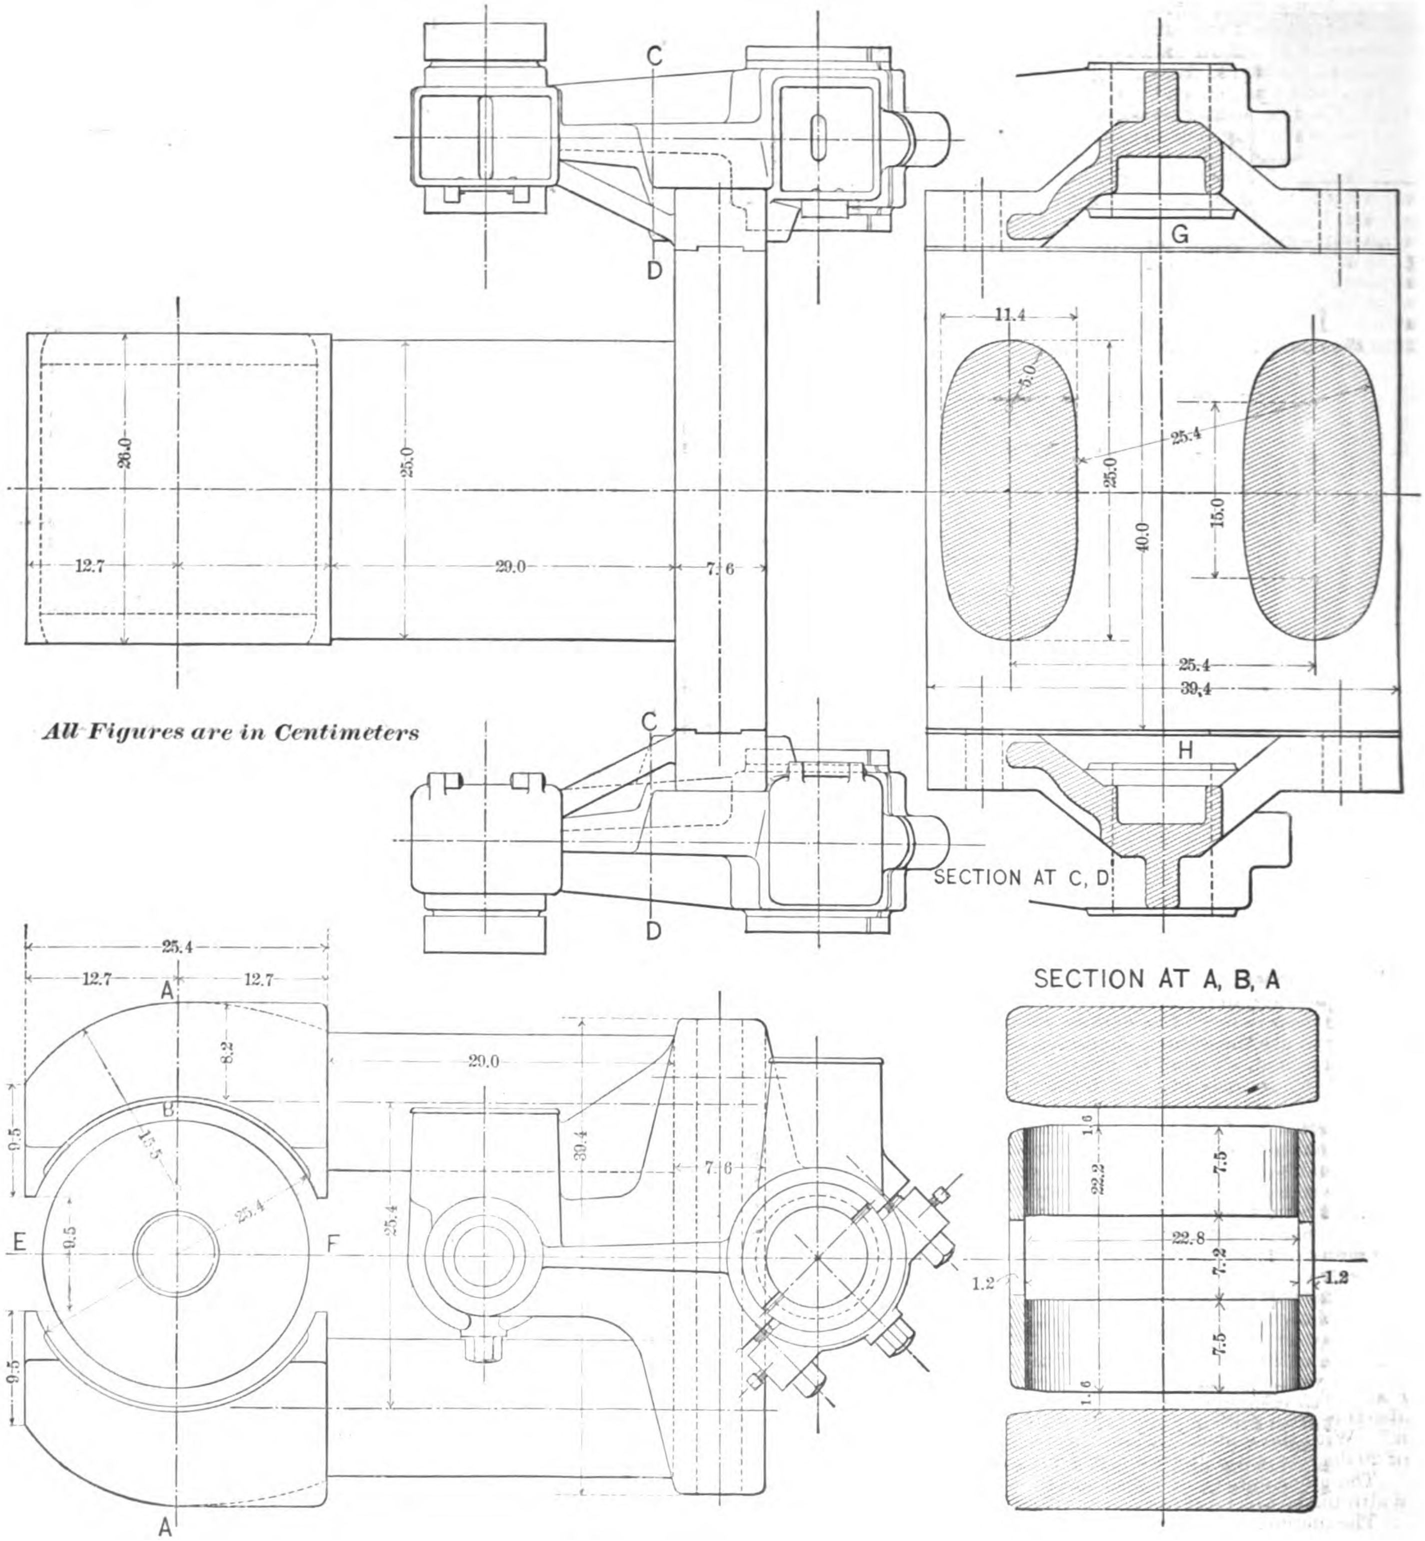
The averages, viz.:

Error of horizontal-slit photometer, 1.76% (average for spectrum)

Error of polarizing spectro-photometer, 5.20% (average for spectrum),

doubtless afford a fair indication of the relative performance of the two instruments in this peculiarly trying line of work.

At the last annual meeting of the Institute I had the privilege of presenting a brief study of certain personal errors pertaining to the use of the Bunsen photometer. The particular class of errors to which attention was called in that paper[6] are undoubtedly obviated by the use of the horizontal-slit photometer; what new ones the latter instrument may introduce remains to be determined.



All Figures are in Centimeters

Fig. 1.—Sprague Street Car Motor.

MAGNETIC DATA OF THE SPRAGUE STREET CAR MOTOR.[1]

BY H. F. PARSHALL.

Figures giving the ratios of the lines of force through various parts of the magnetic circuit to the lines of force through the armature have occasionally been fully published, the most noticeable being those given in a paper by Hopkinson some years ago. These ratios vary in the same type of dynamo or motor with any change of proportion; or, to put it in another way, in order that these ratios may remain constant in the same type, the ratios of the magnetizing force in the one part of the magnetic circuit to the magnetizing force in the other parts must also remain constant.

In making calculations on various motors made by the Sprague

---

[6] Transactions of the American Institute of Electrical Engineers, vol. 6, p. 335.

[1] A paper read before the American Institute of Electrical Engineers, Boston, Mass., May 21st, 1890.

Company, I have found it necessary to confirm the assumed values of these ratios by measurements. It is the object of this paper to give the results of the measurements made on the street car motor, together with sufficient description, to make the values found of some use to those engaged in similar work. If I had had any intention of publishing these results, I would have endeavored to make them, in some ways, more complete than they now are, but so little detailed information exists on this subject, I have decided to give the result of my work up to date on this particular motor. The conditions under which this work has been carried on have not at all times been the most favorable for accuracy, but in the main, the results have been satisfactory.

Figs. 1 and 1a, show the various peculiarities of the magnetic circuit, and give the dimensions of the several parts. The most noticeable points are:

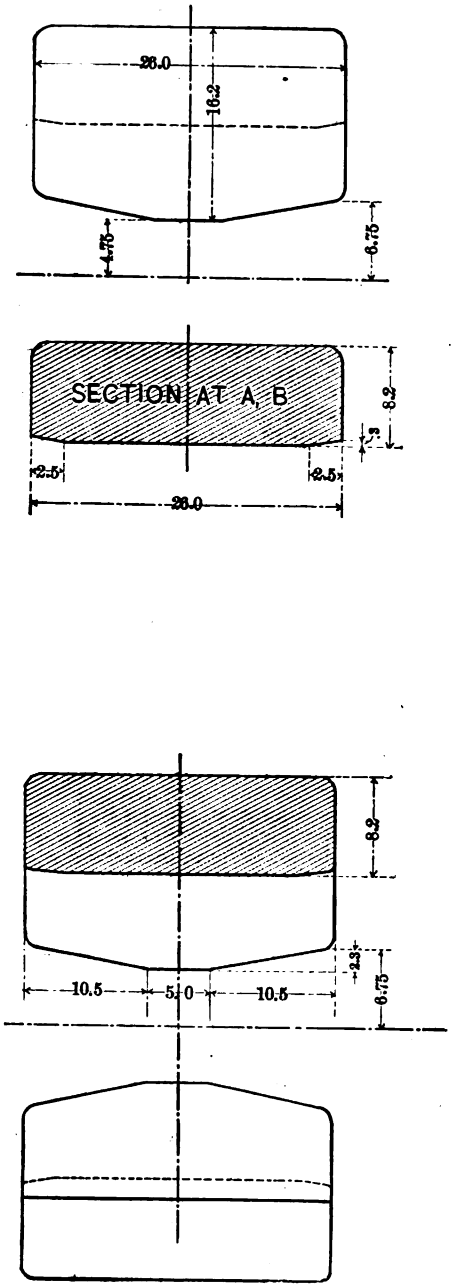


Fig. 1a.—Sprague Street Car Motor.

The bell mouthing of the pole pieces shown in the section "A B." This bell mouthing greatly lessens the sparking, as does also the cutting away of the tips of the pole pieces, as shown in "A B." With these modifications the brushes can be shifted an angle of 20 degrees without serious sparking.

The other noticeable points are the cast-iron side brackets, the width of the yoke and its comparative thinness.

The method of getting the ratio of the lines of force in one part to the lines of force in another was the usual one. Coils of a few turns were wound around these parts, and connected to a ballistic galvanometer, and when the needle was standing at zero, a known magnetising force was suddenly reversed.

The galvanometer used was an Edelmann with a heavy ring form of needle, very slightly damped. The deflections being small, it was assumed that the first throw was proportional to the induction through the measuring coil. The magnetizing coils were those commonly used on this motor.

Each coil was wound approximately to a depth of 4 centimetres, and along the cores 8.5 centimetres.

Coils were as follows:

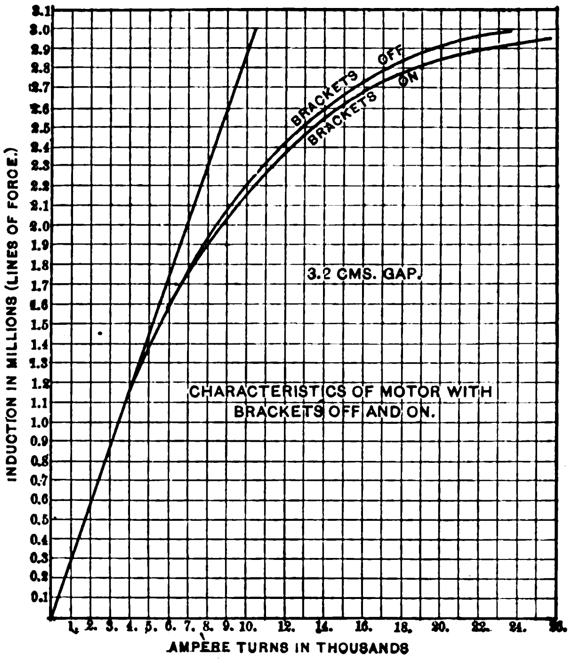

Fig. 2

First. Nearest the pole piece, 28 turns per layer, 11 layers.

Second. 31 turns per layer, 11 layers.

Third. 31 turns per layer, 13 layers.

This gives 2,104 turns for both cores, or with a current of 6.75 amperes, which was used throughout, a magnetizing force of 14,200 ampere turns.

By noticing the curves in Fig. 2 it will be seen that this is the part of the characteristic upon which the motor is most frequently worked. With different values of magnetizing force, different values of the ratios would be found. This becomes evident when we remember that the resistance of the gap remains constant, while the resistance of the iron increases with the magnetizing force. For this reason the curves of magnetization of the *different* parts of the magnetic circuit are not given.

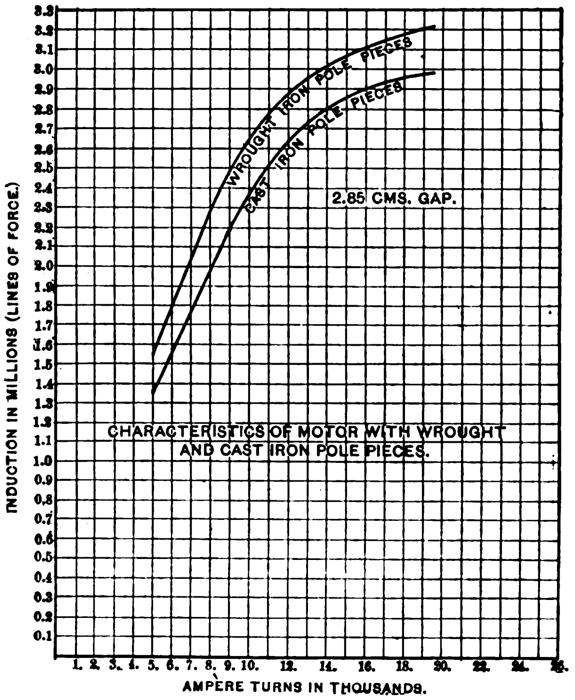

Fig. 3

The measuring coils were 4 turns of wire wound around the armature core at E. F., on the pole piece; at A. B., on the magnet core, midway between the ends; and on the yoke at G. H. Had it been possible a coil would have been wound around both the yoke and side brackets.

The following values were found:

$$\left.\frac{\text{Lines through magnet}}{\text{Lines through armature}}\right\} 1.45$$

$$\left.\frac{\text{Lines through middle of yoke}}{\text{Lines through armature}}\right\} 1.27$$

$$\left.\frac{\text{Lines through middle pole piece}}{\text{Lines through armature}}\right\} 0.666$$

Cast-iron pole pieces.

$$\left.\frac{\text{Lines through magnet}}{\text{Lines through armature}}\right\} 1.52$$

$$\left.\frac{\text{Lines through middle of yoke}}{\text{Lines through armature}}\right\} 1.33$$

$$\left.\frac{\text{Lines through middle pole pieces}}{\text{Lines through armature}}\right\} 0.7$$

The effect of the leakage from the side brackets is shown in Fig. 2, the upper curve being the characteristic with them removed, and the lower curve being the characteristic with brackets on. The dropping of the curve shows that the magnet cores are sooner saturated with the brackets on. The difference is small. It would be somewhat greater did not the brackets reinforce the yoke. These curves were first obtained by separately exciting the fields, and taking the number of revolutions, with a driving current of one ampere through the armature.

The lower curve has, by comparison, been found to be a close approximation to the characteristic when the armature is run with currents for which it was designed.

Fig. 3 shows the characteristics of two motors, one with the wrought-iron pole piece, and the other with the cast-iron pole piece, the gap being 2.85 instead of 3.2, the side brackets being on in each case. The difference between these two characteristics is somewhat striking, and carries its own lesson.

I wish here to acknowledge my indebtedness to Mr. G. J. Scott for the assistance he has given me in making measurements.

Fig. 1a shows two forms of pole piece; one has a full line. This is the cast-iron; the dotted line shows the wrought-iron pole piece.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Discontinuing Subway Litigation.—Buying a Long Distance Telephone Line.—Death of Roloson, the Crack "Fast Sender."

ELIHU ROOT, on behalf of the Manhattan Electric Light Co., has filed in the Supreme Court a discontinuance of the suit of the various electric light companies against the subway company. Mr. Root said that the reason for the discontinuance was that the injunctions issued by the General Term to restrain the companies had defeated the scheme by which the Board of Electrical Control proposed to turn over the control of the subways to the Westinghouse Company, and thus removed the only cause of action which the electric companies had. As their purpose was accomplished, the discontinuance had been ordered.

At last week's meeting of the Aqueduct Board, a resolution providing for the construction of a telephone line to connect the several stations along the line of the new aqueduct was adopted. The Metropolitan Telephone and Telegraph Co. wanted the job, offering to construct the line and maintain it for five years for $5,500 a year. But engineer Fteley, claimed that with the co-operation of Public Works Commissioner Gilroy, the line—a double metallic line. with long-distance instruments at the 135th street gatehouse, Shaft 25, South Yonkers, Ardsley, Pocantico, and Croton Dam—could be built for about $5,000, and this plan was adopted.

John W. Roloson, who is believed by most telegraphers to have been the fastest sender in the world, died at his residence in Brooklyn, last week, from injuries received while riding a bicycle near Prospect Park last Sunday. Mr. Roloson attempted to wheel between two wagons, when the horse attached to one of them became frightened, bolted, and ran him down. He received severe internal injuries. Mr. Roloson was night manager of the Postal Telegraph Company, at 187 Broadway, and was one of the most popular telegraphers in the country. He was born 31 years ago in Port Jervis, N. Y. He commenced his career as a telegrapher in this city when he was 18 years old, and has worked for the Western Union, the French Cable, the Bankers and Merchants Company. the United Press, and the Associated Press. In 1884, he made the world's record for fast sending, 500 words in ten minutes and ten seconds. In 1885 he took the first prize in the tournament here, and in the opinion of not a few, he won the first prize in the recent fast-sending tournament, though he was ruled out by the judges. He was a widower, and leaves two children. He was a member of the Brooklyn Bicycle Club, and a governor of the Telegraph Club of this city.

NEW YORK, May 24, 1890.

PITTSBURGH.

Pittsburgh and Allegheny Traction Co.—The Duquesne Traction Co. —Personal Notes.—The Allegheny County Light Co.

THE stockholders of the Pittsburgh and Allegheny Traction Co. met a few days ago to increase the capital stock of the corporation to $3,000,000, for the purpose of changing the motive power on all their roads from horses to electric motors. Their lines are known as the Union line, the Rebecca street line, the Western avenue line and the Troy Hill line. Great improvements will also be necessitated on the Suspension Bridge, a structure over the Allegheny river, which has to be utilized by all other lines. The Pittsburgh and Allegheny Traction Co. is one of the most profitable street car corporations in this town, and it is expected that the change of the motive power will make it even more prosperous.

The Oakmont and Verona Traction Co. was chartered a few days ago, and another electric railroad will be the result in the vicinity of Pittsburgh.

The Duquesne Traction Co. and the Pittsburgh Traction Co. are about to fight out their difficulties in the Supreme Court, Philadelphia. These two corporations have for some time been at loggerheads as to who should have the right of laying tracks on certain streets in this city.

Mr. J. E. Powell, superintendent of electricity of the Treasury department, Washington, D. C., has arrived in the city to look after the wiring which is to be done in the new government building.

The Birmingham Traction Co., which is to convert its road into an electric street car line, has broken ground for laying new tracks and the cars are expected to be running in the fall.

Mr. L. B. Stillwell, well known as one of the capable assistants to electrician Shallenberger, of the Westinghouse Electric Co., sailed for England a few days ago. Mr. Stillwell will remain on the other side for a considerable time to devote his attention to work connected with the Westinghouse Electric Co., Limited, of London.

The Allegheny County Light Co. of this city have now 32,000 16 c. p. lamps connected and in nightly operation. They added lately two new 60 light arc machines of the Westinghouse arc light type to their plant and they also installed a 75 h. p. incandescent motor machine. The company have the floor of its central station covered with a paint containing a mixture of varnish and wax which has the peculiar property of driving off all the oil dropping on the floor, and thus keeping it constantly clean. A number of electric light men who have seen the floor became so much impressed with the advantage of this scheme that they have also adopted it.

PITTSBURGH, May 24, 1890.

BOSTON.

Dinner by the Boston Electric Club to the Electrical Engineers—A Trip over the Electric Roads—Consumption of Gas and Electricity —Consolidation of Gas and Electric Companies—Regulation of Overhead Wires.

THE most important electric event of the past week was the visit of the American Institute of Electrical Engineers to this city. A full report of their sayings and doings will be found in another column. In the evening of Wednesday, the first day of their visit, the Boston Electric Club had the honor of entertaining the members of the Institute at dinner at the Parker House, when there were present about 180 members and guests, making it by far the most important gathering ever held under the auspices of the Club. Mr. S. E. Barton read a paper on the "Relation between Fire Insurance and Electric Interests from the Underwriters' Standpoint," which was much enjoyed. The dinner itself was the best which the Club ever gave, and the proprietors of the Parker House have every reason to feel satisfied at their success. After Mr. Barton's paper, there was considerable speech making on various topics, the discussion of the paper having been postponed to another occasion. Mr. Cram, as president of the Club officiated, and introduced in a neat and appropriate manner the gentlemen who spoke. Professor Elihu Thomson, the retiring president of the Institute of Electrical Engineers, as a member of the Institute thanked the Club for its courtesy, and as a member of the club welcomed the members of the Institute as guests. Professor Anthony, the newly elected president of the Institute was next called upon, and made a few remarks relating to the absorbing interest which is manifested in electrical matters. Mr. Ralph W. Pope, gave a humorous outline of the programme for the following day, and paid a high compliment to the hospitality of the East. Mr. L. S. Dumoulin, of the West End road, then made a few facetious remarks, and invited all the members and their friends to partake of the hospitality of the West End Street Railway Company on the following day. Capt. Griffin related a few humorous anecdotes, and was followed by Mr. C. F. Pritchard, president of the Association of Gas Engineers, who spoke warmly in favor of the close alliance of gas and electric interests. Mr. Joseph Wetzler, of THE ELECTRICAL ENGINEER, which the chairman characterized as the foremost electrical journal of the day, then spoke on behalf of the Electrical Press, and in the course of his remarks deplored the action of the daily press in so often deceiving the minds of the public on electrical matters. Prof. E. L. Nichols, of Cornell University, Senator Metcalf, of the Massachusetts Legislature, and F. L. Pope, made a few appropriate remarks, after which letters of regret were read from Mayor Hart, Gen. Francis A. Walker, and Col. G. H. Campbell.

On the following day, Thursday, a brief visit was made to the rooms of the Institute of Technology, and then, under the able guidance of Mr. Dumoulin and Mr. Mansfield, a visit was made to the Albany street power station of the West End road. Much interest was taken in the massive foundation work for the 1,000 horse-power engines, and the members were all enthused over the careful, and complete drawings of the proposed station, which were ably explained by Mr. F. S. Pearson. Carriages then took the members back to Park Square, where special cars had been provided and a most enjoyable flying trip was made on the electric line to Chestnut Hill, and back to the Parker House, where the West End Company had prepared a most elegant and récherché lunch. In the afternoon a visit was made to the works of the Thomson-Houston Electric Company, and the Thomson Welding Company at Lynn, Professor Thomson himself escorting the party and showing them every courtesy. Altogether the visit of the Institute to Boston was a most successful and enjoyable one, and it to be hoped that another meeting may be arranged to be held in is the East at no very distant date.

The citizens of East Boston are now clamoring for electric cars, and propose to hold a mass meeting for the purpose of inducing the West End Company to comply with their requests.

The new open Robinson radial car has been tested on the West End road this past week and pronounced a success. The arrangement of the trucks has been frequently described, and it seems probable that their use will become general in a very short time.

In an exhaustive circular on the Bay State Gas Co., Messrs. Devens, Lyman & Co. make the following statement, which may be of interest to electrical engineers:—"It is a fact that the use of electric lights increases the consumption of gas, as people become more accustomed to more light and use more, and the consumption of gas as a fuel is also a growing factor in the manufacture of it. The consumption of gas in the city of Boston has increased about 8 to 10 per cent. a year, and is still increasing; therefore, from the above facts there would seem to be no reasonable fear that electric lighting will injure the business of gas companies."

The Suburban Electric Light & Power Co. have filed another petition in the Supreme Court for a writ of mandamus to compel the board of aldermen to allow them to erect electric light poles.

In the Massachusetts Legislature, the house has passed the bill to authorize the consolidation of gas and electric companies, after adopting an amendment to limit the capital of the new company thus formed to the amount of the stock already issued by the companies which consolidate.

An extended debate occurred on the bill relating to the regulation and supervision of wires over streets or buildings in cities. Mr. Stearns, of Salem, opened the discussion by moving a long series of amendments, sweeping in character, making the bill apply to all cities of 50,000 or more inhabitants; that the wires shall be suitably insulated; that the bill shall apply to all overhead wires; that street railway power wires shall not be insulated, and that the powers of the wire supervisors shall be enlarged. Mr. Means, of Boston, said the proposed amendments, if adopted, would kill the bill. He moved to amend by providing that fuses should be placed at such points in the electric circuit as should effectually protect buildings from fire, instead of having them indiscriminately placed at all points of entrance. All the amendments offered by Mr. Stearns, of Salem, were rejected, Mr. Means' amendments adopted, and the bill was passed to be engrossed by an almost unanimous vote.

BOSTON, May 24, 1890.

In the United States Circuit Court at Boston, on May 21, the time for taking testimony in the case of the United States against the Bell Telephone Company was extended to Oct. 1, the court ordering that no testimony be taken from July 15 to Aug. 30, inclusive. This extension was asked by Mr. Roberts, who has charge of the case before the examiner, because the condition of his health necessitated a vacation during July and August.

LEGAL NOTES.

CLAIMING THE INCANDESCENT LAMP.

WALTER K. FREEMAN vs. THE U. S. ELECTRIC LIGHT CO.

Before Judge Ingraham in the New York Supreme Court, on May 22, trial was begun of a suit brought by Walter K. Freeman against the United States Electric Lighting Company. In his complaint, Freeman avers that he invented the incandescent electric lamp prior to August, 1878, and sent a lamp to Edison at Menlo Park, N. J., and that about two years afterward Edison announced the invention to the world as his own. He then asserts that Edison offered him $50,000 if he would refrain from mentioning the fact that he was in reality the inventor and had sent sample lamps to Edison.

The lamp he claims to have sent to Edison embodied all the features of the Edison lamp, consisting of a carbon filament of high resistance secured to platinum wires and enclosed in a glass globe from which the air had been exhausted.

Freeman now claims a residence in this city, but is connected with a business at Eau Claire, Wis. He was at Racine in 1878, when he sent the lamp, as alleged, to Edison, and was subsequently taken into the employ of the defendant company during a part of the year 1882.

He brings his suit against the United States Electric Lighting Company, alleging that a written contract was made with that company in June, 1881, which provided that if a patent were obtained on Freeman's alleged inventions which should be superior to the patent which Edison had at that time obtained, the company should have the option of taking it or paying him $100,000. No patent was granted, and he claims that the company was derelict in pushing the claim. He lays his damages at $150,000, part of which is for salary due for failure of the company to continue him in its employment.

It is contended by the defence that the contract was not made for the benefit of the company, that the defendant made the application to the Patent Office in his own behalf, and that his application was rejected as invalid.

It is further claimed that Freeman secured the contract by false representations and pursuant to a scheme of fraud to get money and employment without giving anything of value in return.

DENIAL OF A WRIT OF ERROR TO KEMMLER.—OPINION BY CHIEF JUSTICE FULLER, U. S. SUPREME COURT.

At Washington on May 23, the Supreme Court of the United States denied the application for a writ of error in the case of Kemmler, under the sentence of death by electricity. The opinion is by Chief Justice Fuller. It first recites the proceedings in the lower courts leading up to the bringing of the case to this court. The Court says that it is urged in Kemmler's behalf that the fourteenth amendment is a prohibition on the State of the imposition of cruel and unusual punishment, this being included in the term "due process of law." The origin of the phrase "cruel and unusual punishment," the Court said, was in the English Act of Settlement of 1688, and meant that barbarous methods of punishment should not be inflicted. It meant that a man should not be sentenced to death by torture, but did not mean that the death penalty itself was cruel. The New York Court of Appeals, the opinion says, held that the punishment inflicted on Kemmler was unusual, but that there was no evidence to show that it was cruel. The Legislature of New York had the facts bearing upon this question, and the Court must presume that the Legislature had devised a punishment it thought less cruel than the former mode. That decision, the Court says, was not against any special privilege set up by the prisoner, and was so plainly right that the Court would not be justified in overruling it.

The Fourteenth Amendment did not materially change the whole theory of the Government. Citizens still remain citizens, both of the State and of the United States. The only change is that the amendment furnishes an additional guarantee against encroachment by the State upon the fundamental rights of the citizens. The privileges and immunities of citizens of the United States are, indeed, protected by them. Those are the privileges arising out of the essential nature and character of the national Government.

The Court quotes the opinion in the Hurtade case on the meaning of the phrase "due process of law." The change in form of death was within the legitimate sphere of the legislative power of the State. The Legislature of the State of New York determined that it did not inflict cruel and unusual punishment, and its courts have sustained that determination. This Court cannot see that the prisoner has been deprived of due process of law.

In order to reverse the judgment this Court should be compelled to hold that the Court of Appeals had committed an error so gross as to deprive the prisoner of his constitutional rights. The Court has no hesitation in saying it cannot do this.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued May 20, 1890.

Alarms and Signals:—*Electric Signal-Circuit*, O. W. Hart. 428,095. *Electric Semaphore Apparatus*, F. Stitzel and C. Weinedel, 428,576. *Watchman's Time-Recorder*, C. E. Egan and H. F. Gray, 428,583.

Conductors, Conduits and Insulators:—*Elevated Conduit for Electric Wires*, H. N. Ruttan, 428,145. *Electric Insulator*, E. Andrews, 428,545.

Distribution:—*Electrical Converter*, W. Stanley, Jr., 428,574. *Method of Building Electrical Converters*, W. Stanley, Jr., 428,575.

Dynamos and Motors:—*Commutator-Brush for Dynamos*, L. Van Brown, 428,073. *Electric Motor Regulator*, W. H. Knight, 428,169. *Armature for Dynamos*, A. Schmid, 428,289. *Regulator for Electric Current Generators*, G. Pfannkuche, 428,317. *Dynamo-Electric Machine or Electric Motor*, E. Croasdale, 428,380. *Electric Motor*, W. H. Chapman, 428,454. *Electric Motor or Generator*, H. Groswith, 428,481.

Galvanic Batteries:—*Galvanic Battery*, A. J. MacDonald, 428,116.

Ignition:—*Electric Gas Lighter*, R. T. Walton, 428,433.

Lamps and Appurtenances:—*Arc Lamp*, C. F. Breese, 428,066 *Device for Elevating and Lowering Electric Lamps*, J. B. Morris and G. Voll, 428,401. *Alternating Current Arc Lamp*, Geo. Westinghouse, Jr., 428,435.

Measurement:—*Electric Meter*, A Frager, 428,084. *Electric Meter*, J. F. Mehren, 428,280. *Electric Meter*, E. W. Von Siemens, 428,290.

Metal-Working:—*Electric Furnace for Melting Metals*, E. A. Colby, 428,378. *Process of Welding Metals Electrically*, C. L. Coffin, 428,459. *Process of Melting, Refining and Casting Metals*, E A. Colby, 428,552.

Miscellaneous:—*Process of Electro-Deposition*, D. Garrett, 428,087. *Magnetic Lock*, W. W. Fenner, 428,247. *Magnetic Lock*, J. Schneider, 428,256. *Graphophone*, M. L. Deering, 428,273. *Electric Induction Device*, E. A. Colby, 428,379. *Voltaic Armor*, A. L. Scott, 428,420. *Electrical Heater*, J. I. Ashbaugh, 428,443. *Electric Bath-Brush*, R. E. Williams, 428,540. *Electrical Cut-Out*, W. J. Jenks, 428,564.

Railways and Appliances:—*Insulator for Electric Railway Wires*, H. P. Brown, 428,071. *Trolley System for Electric Railways*, H. P. Brown, 428,072. *Electric Railway*, R. M. Hunter, 428,098. *Trolley-Arm Support for Electric Railways*, F. B. Rae, 428,136. *Electric Locomotive*, J. F. McLaughlin, 428,175. *Electric Railway*, R. M. Hunter, 428,210 and 428,211. *Electric Railway*, J. B. Legg and J. Nill, 428,499. *Electric Communication with Railway Trains*, T. J. Houck, 428,562.

Telegraphs:—*Synchronous Multiplex Telegraphy*, F. J. Patten, 428,221, 428,224, 428,225 and 428,226. *Multiplex Telegraph*, F. J. Patten, 428,222. *Multiplex Telegraphy*, F. J. Patten, 428,223.

Telephones and Apparatus:—*Telephone*, J. G. Ludwig, 428,174. *Three-wire Multiple Switch-Board System*, E. P. Warner, 428,189. *Registering Attachment for Telephones*, R. J. & J. S. Storey, 428,427.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"SAFETY" CABLES IN THE NEW YORK SUBWAYS.

Mr. L. E. Requa, the general manager of the Safety Insulated Wire & Cable Co., of 234 West 29th street, this city, has in his possession an interesting letter from the late D. L. Gibbens, subway commissioner, written a few days before his death; we give the complete text of the letter below as follows:

New York, April 17, 1800.

Dear Sir:—In reply to your inquiry concerning the use of the cable manufactured by your Company in the subways in New York City and known as the "Safety Cable," I would say that it is within my knowledge that over one hundred miles of this cable has been in constant operation for electric lighting purposes in the said subways for periods ranging from two months to over one year, and during that time not a single defect has been reported, nor have there been brought to my knowledge any trouble or fault in such cables whatsoever. There have been two instances where, owing to careless workmanship and mechanical injury, defects have been occasioned, but these were not the fault of the manufacturer of the cable nor were they due to any inherent defect in the insulation used, or the method of manufacture. The very remarkable and senseless opposition of many electricians to the employment of underground wire for electric lighting prior to the successful tests made in the subways in this city took the form of a prophecy that underground wire for the purpose of conducting electricity for high tension lighting and power circuits would surely fail. The success of the cable manufacturers in meeting the question was most gratifying to the members of the Board of Electrical Control and undoubtedly will be so to the public generally when the facts are fully understood. Much of the confidence which is felt in the success of the underground service is undoubtedly due to your excellent work.

Yours very truly,
Daniel L. Gibbens,
Ex. Com. Board of Electrical Control.

It is worthy of note in this connection that Mr. Wm. Maver, Jr., the electrician of the Consolidated (subway) company, has made some tests on lead covered "Safety" cables made and laid for the Mt. Morris Electric Light Co., in this city, with the object of determining the effects of high temperature on the insulation of cables lying near the steam heating mains.

Wednesday, March 26, 1890, 2.30 p. m. Location of testing place, Duane street near Broadway (basement plumber's shop.) Constant 25,000 megohms.

First Test—Conductor A, No. 6 B. & S. In subway from Duane to Beaver street, Broadway. Total insulation resistance after one minute electrification, 1,250 megohms. Estimating length of conductor as 8-10 mile, insulation resistance per mile, 1,000 megohms.

Second Test—Conductor B, No. 2 B. & S. In subway parallel with conductor A, from Duane street to Beaver. Total insulation resistance after one minute electrification, 1,250 megohms. Insulation resistance per mile, 1,000 megohms.

Third Test.—Conductors A and B tested together. Length 1.6 miles. Total insulation resistance after one minute, 625 megohms. Insulation resistance per mile, 1,000 megohms.

Fourth Test.—Conductor C, No. 2 B. & S. In subway from Duane and Broadway to 14th street and 6th avenue. Estimated length, 2.2 miles. Total insulation resistance after one minute, 833 megohms. Insulation resistance per mile, 1832.6 megohms.

Fifth Test.—Conductor D, No. 6 B. & S. In subway from Duane to Houston streets. Estimated length, .75 mile. Total insulation resistance after one minute, 2,500 megohms. Insulation resistance per mile, 1,875 megohms.

Sixth Test.—Conductors C and D tested together. Estimated length 2.95 miles. Total insulation resistance after one minute, 625 megohms. Insulation resistance per mile, 1,843 megohms.

Seventh Test.—Conductors A B C D, tested together. Estimated length, 4.55 miles; 1.6 miles of same in heated district. Total insulation resistance after one minute, 312.4 megohms. Insulation resistance per mile, 1,421.8 megohms.

Tests closed 4.45 P. M.

Conductors A & D will be joined up as part of one circuit, B and C as part of another.

"The temperature in some of the manholes," says Mr. Maver, "has been found by actual measurement to exceed 150 deg. F. The results of tests show an insulation resistance of all the conductors much higher than is required by the subway rules. The conductors have been in the subways, heated districts included, a sufficient time, in my opinion, to develop any tendency to a marked fall in the insulation due to increased temperature if such fall were to follow the placing of the cables in the heated area."

THE McCREARY ELECTRICAL SPECIALTY COMPANY.

Mr. A. A. McCreary, has issued a circular to his friends and the trade in which he says:

"I beg to announce the incorporation of The McCreary Electrical Specialty Co., successors to me in carrying on the business of manufacturing and placing upon the market patented electrical specialties. In addition to my well-known reflectors and half shades, I have acquired the sole control of several valuable electrical patents that I shall take pleasure in calling your attention to in a few days when they will be ready for the market."

The business of the company will be carried on at 18 and 20 Curtlandt street. Mr. McCreary is the vice-president and general manager of the company and Mr. C. C. Foster secretary and treasurer. The favorable reception already accorded to Mr. McCreary's specialties awaits the novelties he will shortly bring to notice.

R. D. WILSON & COMPANY.

Messrs. R. D. Wilson & Co., whose office is at 113 Devonshire street, Boston, are making a specialty of electrical securities, and though organized only about two years ago, are very widely and favorably known as exploiters of electrical stocks. Every stock which they have yet handled has become successful. They were the first to exploit the Thomson-Houston and the Thomson Welding stocks before they were put on the board. They are now devoting a large part of their time to the successful pushing of the New England Printing Telegraph Company, and are offering a limited number of the shares of this company at a very reasonable rate. This company is the licensee for the New England States of the Essick Printing Telegraph, which is creating quite a sensation amongst electricians and capitalists, all being very favorably impressed with it. Messrs. R. D. Wilson & Co. are recently in receipt of the following letter from Prof. Moses G. Farmer, whose opinion is extremely valuable:

At your request I have examined the working of the 'Essick Page Printer,' on a line from New York to Boston. I am highly pleased. I may frankly say that I came here prejudiced, and did not expect to see what I have seen here to-day. The instrument did its work well, and I see no reason why it is not practical for commercial purposes. I have examined the mechanical and electrical features, and find it simple and inexpensive in construction. I see in it new electrical features which are certainly very valuable. I see no reason why the system is not thoroughly practical for all telegraphic purposes, and I believe that the system is all that the inventor claims for it.

BRUSH LIGHT AND POWER PLANTS.

The Brush Electric Company, of Cleveland, O., are equipping central stations with their alternating apparatus as follows: Jeffersonville, Ind., Electric Light Company, 600 lights; S. & J. C. Atlee, Fort Madison, Iowa, 1,000; Red Bank, N. J., Electric Illuminating Company, 1,000; Marysville, Cal., Coal Gas Company, 1,000; Evansville, Ind., Gas and Electric Light Company, 1,000. For arc lighting stations they have sold the Hampton, Va., Electric Light Company apparatus for 30 lights, and one for 100 to the Haverhill, Mass., Electric Company. Isolated arc plants have been sold to J. P. Witherow & Co., New Castle, Pa., 30 lights; Cleveland Rolling Mill Company, 30 lights; Michigan Agricultural College, Lansing; C. S. Robinson, Princeton, N. J., and steamboats owned by R. D. Blair, Osceola, Miss., and St. Louis and Mississippi Valley Transportation Company. Brush motors have been furnished to Princeton College, N. J., and Beecher Furnace Company, Cleveland; an isolated power plant to the Dayton, Tenn., Coal and Iron Company; also a motor for hoisting purposes at Aspen, Col., of the new 440 volt constant potential type; a plating dynamo to the Taylor and Boggis Foundry Company, of Cleveland.

WESTINGHOUSE ELECTRIC STREET RAILROAD FOR LANSING.

Lansing, the capital of Michigan, is to have a model electric street railway, built by the Westinghouse Electric Railway Co. The Westinghouse people guarantee that every road will be a model to which prospective builders can confidently refer for perfection of system in every detail, with the knowledge that every part will be of the latest and most approved pattern known in electrical science. The road will be pushed to completion at once.

THE McDOUGALL-MARTIN ELECTRIC COMPANY.

During the next fortnight the McDougall-Martin Electric Co., of 120 Times Building, this city, will demonstrate the practicability of the storage battery system in connection with the McDougall motor which has been specially constructed for that purpose. This car will make 50 miles on a single charge of battery and will, beyond doubt, excite considerable interest and attention in electrical, street railway and other circles.

EUREKA TEMPERED COPPER.

In a letter of May 14, to the Eureka Tempered Copper Co., of North East, Pa., Mr. C. R. Huntley, the general manager of the Brush Electric Light Co. at Buffalo, N. Y., says:

"Some time about eight months ago we began the use of tempered copper for commutator segments on the Brush machine, and we have had remarkable success with its use. We find that they wear about three times as long as ordinary segments made of copper. We have tried the experiment of using tempered copper for brushes and beg leave to report the result. The 1st of March we put a set of brushes on a dynamo and they were not trimmed until the 17th of April. This is a remarkable showing and you may count upon us as staunch advocates and constant users of tempered copper in this line of our business."

The Jeffrey Manufacturing Co., who make the well-known Jeffrey electric coal mining machines at Columbus, O., write as follows:

"In reply to your favor of the 10th, would say that we are using your tempered copper for bearings on our coal mining machines and find it superior to any metal we have used for this purpose. It is subjected to severe work and stands it splendidly."

NEW WESTINGHOUSE PLANTS.

Owing to the rapid increase in the business of the Brush Electric Company of Baltimore, that organization has found it necessary to increase the capacity of its incandescent plant by the addition of a Westinghouse three thousand light alternate current dynamo. This machine will be shipped immediately and installed at the earliest possible moment.

The Wilmington City Electric Company of Wilmington, Delaware, has for some time been contemplating extensive improvements in its electric light plant owing to the great increase of patronage on the part of the citizens of Wilmington. The company has just contracted for a new 750 light machine, Westinghouse alternate current incandescent system, and no time will be lost in the installation.

The Citizens Electric Light Company of Braddock, Pa., has been obliged to increase the capacity of its incandescent lighting plant. A contract was made with the Westinghouse Electric Company a few days ago to furnish a 750 light alternate current dynamo. This addition will give the company a total capacity of 1,400 lights.

The Westinghouse incandescent light is to be employed at the far famed Bar Harbor on the coast of Maine. The Westinghouse Electric Company has just closed an order with Bar Harbor people calling for twenty two hundred and fifty lights capacity in generating apparatus of the alternate current incandescent type.

Saco, Me., has decided to adopt the Westinghouse alternate current system of electric illumination. The initial plant at Saco will consist of one 750 light incandescent dynamo.

Connersville, Ind., is to have the electric light. An electric light company recently organized at that place has just closed negotiations with the Westinghouse Electric Company for a 750 light incandescent dynamo and two forty light arc dynamos, all machines to be of the alternate current type. Mr. J. W. Huston, treasurer of the United States, is the president of the Connersville company.

The Westinghouse Electric Company has just sold a 750 light dynamo which will be used toward dispelling in a measure the darkness of the town of Chanute in the state of Kansas.

EDWARD R. KNOWLES, C. E.

MR. KNOWLES has opened offices at 181 Broadway, this city, and has issued the following professional announcement: "Permit me to notify you that I have associated myself in business with Mr. Ernest C. Webb, counsellor-at-law and solicitor of American and foreign patents, with offices at the above address. Hereafter I shall transact a general engineering and expert business, making a specialty of all branches of electrical work, in which I have had a practical experience continuously since 1879. I shall also give attention to the experting of patent causes, and the construction and testing of electrical and mechanical machines and devices." Mr. Knowles is well known throughout the electrical profession, both as an engineer and as an inventor. Though still a young man he can justly claim to have been a pioneer in the electric lighting field He has also a close familiarity with the newer branches of electrical engineering. Messrs. Knowles and Webb will be represented in Washington, at the Pacific Building by Mr. F. Carragan. In this city the firm will have a branch office also at 22 Cliff street.

ST. LOUIS, MO., ELECTRICAL SUPPLY COMPANY.

THIS company have purchased the business and stock of the old St. Louis Electrical Company (proprietary) and will carry on the business at the familiar stand, 403 North Eighth street. It is their intention to increase and extend their field of operations and usefulness as much as possible, and they will carry a full line of supplies at all times. Parties desiring to place agencies should correspond with them, and purchasers within their large territory should get quotations on any goods needed The company has a capital stock of $25,000. W. L. Scott is president, J. F. Porter, vice-president, and G. W. Brinck, secretary.

THE ILLINOIS ELECTRIC MATERIAL COMPANY.

AN important consolidation has just been effected in the supply business by Mr. Ernest Hoefer, of Bishop White Core and Trinidad Line Wire fame, Mr. Earnest L. Clark, well known in the "pole" business, and Mr. H. S. Winston. The new company just organized by these gentlemen to do a general electric light and power supply business, has been incorporated under the name of "The Illinois Electric Material Company." The company will push with increased vigor the Bishop White Core wires and other specialties manufactured by that company and Trinidad Line wire made by the Trinidad-Heymann Insulated Wire Co., of New York, for which goods they are the sole western agents. They will also pay especial attention to pole and line supplies. A large stock will at all times be carried, and the quickest possible shipments can be made. The offices of the company are located at room 341 Rookery. We wish this new concern the success which will undoubtedly be attained by men of such well-known ability in the supply business. Mr. H. S. Winston is president and treasurer, Mr. Ernest L. Clark, secretary, and Mr. Ernest Hoefer, vice-president and manager.

THE ECONOMIC ELECTRIC MANUFACTURING COMPANY.

The Economic Electric Manufacturing Company of Brockton, Mass., have made a contract with the Siemens-Halske Company of Berlin for the purchase and sale in the United States of the Siemens-Halske incandescent lamp filament. The Economic Company propose to mount these filaments in lamps and sell them as well as their own filaments, and will thus be prepared to supply lamps of every voltage and capacity in ordinary, commercial use. This in connection with their dynamo and motor service will keep their new factory at Brockton in active operation during the summer months. They will shortly have these lamps on exhibition at their offices at 1 Beacon street. The factory is in charge of mechanical superintendent John H. Vinton, and electricians John G. Hubbard, and Edward A. Clark, with Prof. Hooper of Tuffts College as consulting electrician. Work is now being actively carried on in making new patterns of dynamos and motors, and the fitting up of the lamp department, which will have at the outset a capacity of 500 lamps per day.

NATIONAL ELECTRICAL MANUFACTURING COMPANY.

This company, successors to the electrical department of the New Haven Clock Co., have recently removed to 14 and 16 Vesey street, this city, as noted in our last issue, and have sent out another edition of their large, complete and tasteful catalogue of 122 pages, including a full line of supplies, instruments, time and watchman systems, etc. It will be remembered that the National Co. make a specialty of the Microphone battery and the Crowdus dry battery, for both of which they can show a bushel of testimonials. The company are now preparing for more extensive work and will shortly be in the market with their new products.

ECLIPSE WIND ENGINE CO. OF BELOIT, WIS.

The above company has recently filled large orders for its friction clutches, etc., from the Union Depot Railroad Co., St. Louis and the Laclede Gas Co. of that city. Among other large orders is one for an outfit for the transmission of 3,000 h. p. power for the Louisiana Electric Light and Power Co. of New Orleans; also a second order for a rope transmission from the Detroit Electric Light and Power Co. and one for an equipment doubling the capacity of the Queen City Electric Light and Power Co. of Dallas, Tex.

NOVELTY ELECTRICAL SUPPLY COMPANY.

The Novelty Electrical Supply Co. of Cincinnati, E. P. Morris, president, and P. B. Chaney, secretary, are doing a handsome business in their specialties. They have just made a sale to the North-Western Thomson-Houston Co. of Minneapolis, of 1,000 of their patent insulated pulleys, and have received an order for 800 from the Central Electric Co. of Chicago. They have now in use about 13,000 of their pulleys, all of which have been placed on the market since November last. They are also receiving a great many orders for their arc light windlasses, and recently shipped 50 to this city. They have also made a contract with the Cincinnati Street Railway Co. for 1,350 of their patented combination pole tops, and over 10,000 of their patent insulated trolley hangers. In fact, the entire construction in Cincinnati will be done with the appliances of which they are the inventors and owners.

THE GREAT WESTERN ELECTRICAL SUPPLY COMPANY.

We would direct the attention of our readers to the special announcement of Mr. George Cutter respecting the establishment of the headquarters of this new company at 190–192 Fifth avenue, Chicago.

NEW ENGLAND TRADE NOTES.

The Evans Friction Cone Company has secured a contract to furnish their Evans system of driving for the Waltham Electric Light Company, Waltham, Mass. A 800 horse-power compound condensing Armington & Sims engine will be coupled direct to the line shafting, and six dynamos will be driven from the line shaft by Evans pulleys, two of them being 80 horse-power generators for the Newton Street Railroad. The Evans Company have also fitted their driving system to the Waltham Watch Company's electric plant, and will start up in a few days in the Vanderbilt building, New York, a 450 light Loomis incandescent dynamo, driven by a Fitchburg engine.

The Standard Electric Company, of Vermont, have sold, through their Philadelphia agency, a 500 light incandescent dynamo, to be installed in the new mill of G. C. Hetzel & Co., at Chester, Pa.

Mr. D. C. Spruance, of Lewisburg, Pa., has secured the contract for the erection and the complete equipment of a 1,500 light station at Portsmouth, Va. There will be two 750 light Westinghouse alternating dynamos, two compound Westinghouse engines of 75 horse-power each, and about two and one-half miles of pole line work.

Messrs. J. A. Grant & Co., of Boston, have received an order for the complete steam plant of 800 horse-power for the Kingston Electric Light and Power Company, of Kingston, Jamaica, West Indies. The plant will consist of two McIntosh & Seymour compound condensing engines, two steel tubular boilers, heaters, condensers, injectors, pumps, and all necessary fittings. This is the second plant which Messrs. Grant & Co. have shipped to Kingston, Jamaica.

Pettingell, Andrews & Co. report business becoming quite brisk again throughout New England, and Mr. Levi Cofren, their well-known popular representative, has recently closed contracts for large quantities of supplies for the Worcester, Mass., Electric Light Company, Lowell, Mass., Electric Light Corporation, Nashua, N. H., Electric Light Company, Bellows Falls, Vt., Electric Light Company, and the Middlebury, Vt., Electric Light Company.

Mr. Charles L. Ireson, of Boston, has opened a factory in Atlanta, Ga., for the manufacture of leather belting, and has the honor in so doing of possessing the pioneer belt manufactory of the South. Mr. Ireson's belts are well known in the East, and trade has been so steadily growing in the South that he has taken this important step to give his customers every facility for the prompt delivery of all kinds of oak-tanned belting. Reports from the South state that already important orders have been received, and Southern consumers are extremely pleased to have in their midst a factory where they can have their belts made endless, a feature in belting that appears to have been somewhat neglected in the South. Mr. Ireson has sent some of the most expert of his staff to start the business.

WESTERN TRADE NOTES.

The Ft. Wayne Electric Company, through their Chicago office, sold to Litchfield, Minn., a new Wood 25 arc light plant and 500 incandescent lights of the Slattery system last month; and this month they have sold an increase, so that the complete plant now has 40 arc lights and 1,200 incandescents. The Central Electric Light Company, of Chicago, have ordered an increase of their plant, amounting to an addition of 5,000 incandescent lights. The South Side Electric Company, of Chicago, have placed an order for a 10,000 light plant of the Slattery induction system. Armour & Co. have ordered two 1,200 light incandescent plants of the same system. The Oakwood Electric Light Company have just made the third extension of their plant since starting, by the addition of a 60 light new Wood arc dynamo. The incandescent plant, Slattery induction system, recently installed for the same company, will be started up in this station right away.

Schuyler Electric Co. Mr. Wheeler, the expert of the Schuyler Electric Co. is in town looking after the various plants which have been installed here by his company. He reports business as flourishing and the outlook very bright. It is needless to say that the Schuyler plants are giving the same satisfaction to all here as elsewhere, and it is certain that this excellent system will continue to increase rapidly.

The Dawn Electric Construction Co., 154 La Salle street, who manufacture and deal in electric light supplies are very busy notwithstanding the trouble they have had from the recent strikes. They are making a specialty of electric signs the letters and devices of which are formed by means of incandescent lamps and which are very attractive, presenting a beautiful appearance when lighted up. They also represent the Mather Electric Co., and are selling a good stock of that company's apparatus. They handle all kinds of construction work and carry it out in the most thorough manner.

J. R. McKeand & Co. are the sole manufacturers of the Hesson Furnace Grate, quite a number of which have been installed in Chicago, to the great satisfaction of their users. Their offices are located at Room 343, Rookery, where they will be pleased to have a call from all interested in grates.

W. C. Lyman, manufacturer of steam condensing, vacuum exhaust pipe heads, is quite busy filling the demand for these specialties. The advantages claimed for them are numerous, it being a benefit to all non-condensing engines, particularly high speed, and their employment also tends to preserve roofs, walls, etc., from being rotted by exhaust steam. The escape is dry and noiseless and not attended with any back pressure, and a saving is effected in water of from 25 to 75 per cent., according to the length of the connections, and the different conditions of plants working with wet or dry steam. This apparatus has met with great success, and been very largely employed by electric light and power companies.

The National Engineering Bureau, who are located in the Rookery, are very busy, although but recently organized. They are designing quite a number of central station plants, for which they make the drawings and specifications, and then superintend the work of the construction companies, seeing that everything is carried out in the most thorough and complete manner. They will undoubtedly find a large amount of this class of business. By reason of their tried experience and ability, purchasers of plants who employ them to supervise the work can be assured of its excellence throughout.

The Western Electric Co. have just issued a neat and handsomely gotten up catalogue of their testing apparatus. It is replete with illustrations of the various instruments and contains a full and clear description of the same and their uses. The celebrated Rudd ground alarm, which has met with such universal approval among central station men, occupies a prominent position. In this ground alarm, it will be remembered that the indicator is shown by a drop such as those employed on telephone switchboards, the essential part of the system consisting in the application of condensers. In the catalogue are further enumerated combination bridge set, rheostat and galvanometer, testing set for linemen, magneto bell, and Warner testing battery. Altogether it is a very complete and handy pamphlet.

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.

GEO. M. PHELPS, President. F. R. COLVIN, Treas. and Business Manager

Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway*, *New York city*.

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. IX. NEW YORK, JUNE 4, 1890. No. 109

I have far more confidence in the one man who works mentally and bodily at a matter, than in the six who merely talk about it.—Faraday.

THE PRICE TO CHARGE FOR CURRENT.

TWO weeks ago we invited the attention of station superintendents to the opportunities that await them in the development of electric power and in the use of electric current alike for stationary motors and for electric railroads. If we may judge from the comments that have reached us, we have started a discussion that is likely to be of lasting benefit.

Some of our friends and correspondents say that their efforts to develop the electric motor industry are checked by the high prices charged for electric motors. They say that prices for such machines are often too high to bring them into an equal competition with water motors, gas motors, small steam engines, and the like. There may be something in this, but we cannot say that the cost of motors strikes us as being much amiss. It is to be borne in mind that a motor needs no boiler, no smoke stack, no steam exhaust, no fuel, no water, and has no ashes to dispose of. There is moreover generally, or should be, a reduction in insurance rates. In view of its convenience and cost of manufacture, the electric motor is to-day a cheap piece of machinery.

On the other hand, the complaint is made to us by motor companies and motor agents that their efforts are offset by the high price charged for current—rates figuring out sometimes $200, $300, and even more per horse-power per year. What is the truth of this? It surely is not good policy to kill the goose that will lay golden eggs. It would rather pay to run the business so that it yielded a larger return from a larger area. This is what the gas companies are doing in the introduction of gas stoves. Thus, for example, Mr. McMillan, of the La Crosse, Wis., Gas Company, has the following plan, to which the gas journals draw attention: Half of the front page of the local *Republican and Leader* has for some time been devoted to a handsomely illustrated advertisement, in which nine well arranged cuts display as many different styles of cooking and heating devices. Stoves to the number of 100 will be virtually given away on the following basis: The purchaser selects the style of stove desired, when the company will set it in place and properly connect it with gas. The stove will be billed at an agreed-on price, and the connections will be charged for at cost. As soon as the bill is paid the gas will be turned on, whereupon the stove becomes the property of the consumer. Gas may then be used for any purpose without charge until the quantity so consumed, at $2 per 1,000 cubic feet, will equal in value the amount advanced for stove and connections, after which bills for gas will be made out at $1.50 per 1,000, and collected monthly in the usual manner.

Now, how would some such scheme work in the way of developing the demand for electric power? We believe there is something in it. and that a great many of our readers will yet reap a large profit by developing a plan of this nature. It will be noticed that the consumer becomes the owner of the stove. It seems that the right plan also is for the consumer to own the motor. He will then take care of it.

CURRENT AND TRACTION.

WE publish in this issue a contribution by Mr. E. E. Ries on a subject which has recently been discussed in various articles in our columns and the importance of which leads us to devote the space accorded to it. The influence of the passage of the current between wheel and rail upon the coefficient of traction has undergone considerable experiment and study by Mr. Ries; some of the practical results obtained by him are in the direct line of application to railway service. The increase of traction observed with wet and oily rails seems an especially valuable feature in this connection. Mr. Ries also states as the result of his observations that high electromotive force has a tendency to diminish friction, but he gives no reason to account for the phenomenon. If such is the case, it would be interesting to determine the cause, as the principle might be applied in some useful way.

AUTOMATIC ELECTRIC WELDING.

IF the predictions that were at one time made regarding the future applications in the mechanic arts of electric welding may to some have appeared visionary, the actual results obtained to-day must be conceded to have completely verified and justified the prophecy. The members of the American Institute of Electrical Engineers were given an excellent opportunity of satisfying themselves on this point by the exhibition made by Mr. H. Lemp, Jr., after the reading of his paper, which appears elsewhere in this issue; and the visit to the works at Lynn increased their admiration for the distinct progress which was there shown. Mr. Lemp's paper may be said to bring the record of the state of the art down to the present day, and is replete with interesting facts, which have not heretofore been brought out regarding the new processes, and the complete study of which alone made the automatic welding machine a possibility. Not the least interesting details are the description of the various types of transformers employed, and the alternating dynamo with "cubic compounding," by which a constant heating effect is obtained independent of the cross-section and length of the specimens to be welded.

Running Plants By Taxation.

ATTORNEY-GENERAL WATERMAN of Massachusetts, has sent communications to the State Senate and House of Representatives on the question raised by them whether cities and towns have the right to construct and maintain lighting plants. He says that under the provisions of the constitution of the commonwealth they have no such powers, and that any act of the Legislature conferring them would be void. It is said that this decision, since it has been contradicted by the Massachusetts Supreme Court on a similar appeal, will not check the movement in Danvers and elsewhere; but if the discussion settles down to voting on a constitutional amendment, we do not believe that the scheme of the Nationalists, with all that it implies, will go through. It opens too wide a door to corruption and jobbery in municipal affairs.

Primary Batteries at the Paris Exposition.

IN his report on the Electrical Exhibits at the Paris Exposition, which we continued recently, Mr. Hering took up the subject of primary batteries and described a number of cells of recent design. Principal among these was the Renard battery, of which we gave some account recently and which Mr. Hering treated at considerable length on account of its novel properties. While designed especially to be used in connection with balloon propulsion and shown to be the lightest cell for a given power thus far produced, even its inventor expresses his doubts whether electrically-driven balloons will ever be successful implements of war if dependent on primary batteries. He referred evidently to the lack of capacity of any primary cell which has thus far been devised, thus naturally limiting the traveling distance of the balloon. The solution of the difficulty might possibly be found in the application of a storage battery, which, of the same weight as the primary cell, would be able to deliver several times the output of the latter. Such a battery would evidently not only solve many of the difficulties met with in ballooning, but would have a marked influence on electrical propulsion both on land and water, as well as in the unpreempted air.

Electrical Properties of Rarefied Air.

We printed recently the results of the experiments of Dr. James Moser, of Vienna, on the electrical properties of rarefied air, which are calculated to recall vividly to the mind of the student the phenomena observed in gases, and which may play an important part in practical applications. Experiments on the specific inductive capacity of air and other gases were made by Faraday and Harris, who arrived at the results again brought out, that, practically, no difference exists in this value, whatever the nature or degree of rarefaction of the gas employed. Dr. Moser's double-bottom Leyden jar recalls also, not less forcibly, the spherical air condenser of Faraday, with which all his experiments were made.

Electricity In the Bermudas.

WE are enabled to give in this issue some early and timely information in regard to the new Halifax-Bermuda cable, whose importance as one link in a long chain is not yet realized; and we are able to supplement that by some interesting data on electricity in general in the Bermudas. Not a few American electricians now visit that part of the world in winter, and, as one of them, Mr. A. Livingston Bogart, who has recently returned, makes a very bright, chatty and newsy report of what he saw. Mr. Bogart's article brings out two facts, one being that the West Indies generally are subject to peculiar conditions, and the other that no matter what those conditions may be, American electrical manufacturers are fairly entitled to look for good markets all through the Caribbean and adjacent waters or main land. It is pleasant in following Mr. Bogart's graphic descriptions to see how the islands are awaking to new conditions of life and prosperity.

Ventilating Steamship Fire-Rooms.

GREAT complaint is being heard just now among roasted firemen on steamers and men-of-war; and it has been suggested that a remedy would be found in the use of blower engines. We believe, however, that the true remedy can be found in the use of electric motor blowers. Every modern passenger steamer has its electric light plant, and there would be no difficulty in running such blowers, especially as the motors themselves can be placed in any desired position, and are so small as to occupy practically no space that is valuable. In fact it seems to us that there is a large opportunity for electric motors generally in marine work, whether aboard the ship for a variety of purposes, or at the wharf for such work as loading and unloading. We are glad to see that in the U. S. Navy, the use of electric motors has already begun to be appreciated.

The Utilization of Counter-Electromotive Force.

DYNAMIC induction in its various phases plays a prominent part in the practical applications of electricity to-day but we are apt to lose sight of or forget the variety of the forms in which it is applied, and it is well to be occasionaly reminded of them. Acting evidently on this idea Mr. T. D. Lockwood has presented to the Institute a paper treating of one of the most important of the phases of dynamic induction, viz., the counter-electromotive force of self-induction The prominent part which the latter plays in all alternating current apparatus, whether it be the telephone or the converter, is apparent and its utilization in economical regulation of alternating current apparatus is well brought out. Mr. Lockwood's exhaustive historical researches are well known, and in this paper he brought out a number of historical facts of interest and value, evincing a patience in research and a keenness of perception that did him infinite credit.

ELECTRICAL MATTERS IN THE BERMUDAS.

BY A. LIVINGSTON BOGART.

Much has been written and told of the beauties of this group of coral islands—of its crystal clear waters, with their lovely tints from lightest blue through varying shades to purple; of its tropical vegetation and surface covered with flowers of gorgeous hues the year through; its hundreds of dead-white houses, splendid cement-like roads without a suspicion of dust, and above all things, its equable climate without extremes of heat or cold. Experience teaches that nothing so said requires qualification, and the American public have for a number of years flocked to its shores by the hundreds, either to escape the rigor and discomforts of our winters and early springs, or to seek recuperation and rest from overwork.

Notwithstanding its natural beauties, advantages and glorious climate, however, the conservative slowness of its people, apparent lack of energy and absence of means of communication with the outside world have stunted its growth and kept it a quarter of a century behind its nearest neighbors. The thought of being cooped up in 30 square miles of territory, however lovely, in the middle of the ocean, 500 miles from the nearest land, with no mode of communication or egress other than a line of steamers plying only weekly for six months of the year and semi-monthly the rest, has been sufficient to shut out thousands of visitors and capital. If it be considered that the inhabitants are not only dependent upon these steamers for every pound of fresh meat, ice, butter and other luxuries, but that, further, not a single spring, well, or drop of fresh water is obtainable upon these islands other than that produced by showers and stored in cisterns; the apprehension of the timid must be pronounced not without foundation. The absence of telegraphic communication is all the more paradoxical when it is recollected that this is a great British naval and coaling station, with one of the largest floating dry-docks in the world and a large military garrison, and that the prosperity of the inhabitants is almost entirely dependent upon its export of vegetables, such as onions, potatoes, beets and tomatoes, which amounted in 1889 to over $260,000. They are thus cut off from that most vital necessity, the knowledge of current prices and present demand.

A new era is opening for the Islands, however. The people have become awakened to what is going on in the world about them, and great improvements are on the eve of being accomplished. New and modern buildings are projected, the channels are to be dredged so as to admit the largest craft, commodious and substantial docks or wharves are to be built, and commerce with the world invited. That which promises most and which is the present principal topic of conversation is the telegraphic cable connection with Halifax. It has passed the date of hope and speculation and within one month will be an accomplished fact. The cable is not to be put down by the British government as first anticipated, but is the private venture of an English joint stock concern known as "The Halifax and Bermudas Cable Company, Limited," its office being at 33 Old Broad street, London. The capital of the company consists of £120,000 in 4½ per cent. first mortgage debentures, and £50,000 in ordinary shares of £5 each. Sir Alexander Armstrong, K. C. B., is chairman of the board of twelve directors; Mr. Otto Rochs, the general manager. The company has contracted with the well-known firm of W. T. Henley & Co., of London, who have manufactured the cable and supply the vessel to lay it. For this purpose the steamship "Westmeath" has been specially fitted with tanks, machinery and instruments, together with the iron huts to be used at each end of the line, they to be erected at the landing of the shore cables. The "Westmeath" is now on her way to Halifax with 874 knots of cable on board, and on her arrival will immediately proceed to Bermuda, laying the line. The expedition will be under the charge of Captain Stiffe, of the Indian navy, acting for the contractors, Mr. R. Peake being on board representing the Cable Company.

The S. S. "Westmeath" sailed from London on the 22d ult. with the cable to connect the two points above named. The "Westmeath" is not a regular cable ship but has been fitted up for the work by the contractors, the W. T. Henley & Co., who have utilized the tanks and cable machinery taken out of the "Roddam" after that vessel had completed the laying of the French West Indian cables.

The "Westmeath" is a vessel of about 3,000 tons register. She is expected to arrive at Bermuda about June 1st and after landing the stores for the equipment of the Bermuda station, will land the shore end there and pay out a short distance seawards. The cable will then be cut and buoyed and the "Westmeath" will proceed to Halifax, taking soundings on the way. A line of soundings on this route was made by the "Challenger" and deep water with level bottom was encountered, so that the work of the "Westmeath" will be chiefly confined to making an accurate survey of the ground at each end of the line; that is from Bermuda into deep water, and approaching Halifax, from deep water to the edge of the Labrador bank.

At Halifax, where the "Westmeath" will probably arrive some time in the second week of June, the northern shore end will be landed and the ship will start paying out toward Bermuda. It was originally intended to proceed the other way about, laying from Bermuda up to Halifax, but owing to the prevalence of fog at this time of year it was decided that there would be risk of delay, as searching for a cable buoy in a thick fog would be worse than looking for a needle in the proverbial bundle of hay. According to the present plan of operations, although the ship may start in foggy weather, she will soon steam into sunnier climes. It is estimated that, all going well, the work of laying the cable will occupy some six or seven days, so that communication with Bermuda should be established before the end of June.

The cable conductor consists of a strand of seven copper wires, 120 lbs. per knot, insulated with three alternate coatings of gutta percha and Chatterton's compound, 150 lbs. per knot. This core is covered with a serving of jute yarn steeped in "cutch" or preservative mixture applied wet, and then whipped with three-thread jute yarn to keep the serving in place. The deep sea cable is served with 16 No. .099 galvanized homogeneous iron wire. The "intermediate A" is sheathed with 12 No. 8 (B. W. G.) and "intermediate B" with 12 No. 5 wires. The shore end consists of "intermediate A" sheathed with twelve strands of three No. 6 wires. The whole of the above is served with two coats of Russian hemp, laid on in opposite directions, and three coatings of bituminous compound, the first of which is put on next to the wires, and the others over a layer of yarn.

The approximate weight of shore end, intermediate A, B, and deep sea cables, is 14, 5, 3 and 1 tons per knot respectively. The conductor resistance is 10.5 ohms per knot at 75 degrees Fahrenheit. The gutta percha resistance after 24 hours immersion in water at 75 degrees is to be not less than 1,000 megohms per knot after one minute's electrification. The instruments to be employed are the modified form of syphon recorder.

Although the Cable Company receives a subsidy of £8,100 per annum for twenty years, it is not a government line, but will be opened for general commercial business daily from 8 A. M. to 8 P. M., and the greatest amount of traffic is anticipated between New York and Bermuda; but it cannot but prove of the utmost service to the merchant marine of the world, making Bermuda a calling port for vessels plying between Europe, the West Indies, Gulf and South America. Arrangements are now being negotiated with all American, Canadian and European lines for a general interchange of business.

This entire work is being performed under the direction of the well-known cable engineer, Mr. Joseph Rippon, who is the superintendent of the electrical affairs of the Halifax & Bermudas Cable Co., and who will remain in full charge of the plant with headquarters at Bermuda. This gentleman has fully completed all arrangements for the landing of the cable, erection of huts, etc., at both ends of the line, and is now at Bermuda, where he will join the cable steamer "Westmeath," in order to be present at all the operations connected with the laying down of the cable.

Mr. Rippon, who is a native of Yorkshire, England, although but 36 years of age, has had a most extended experience in this class of engineering work, having been connected with the laying, repair or surveys for some of the most notable cables put down during the last twenty years, as the following short summary of his work will show:

1870 to 1880 in India and Brazil, laying the Western and Brazil cables; 1880, laying cables in the Gulf of St. Lawrence and Bay of Fundy; 1881, cables in the Mexican Gulf and survey for cable between Demerara and Para; 1881 to 1882, Central and South American cables in the Mexican Gulf and Pacific; 1883, repairs of the two "Lizard-Bilbao" cables. The same year he took up the instrument department of the Silvertown Telegraph Works, for which company he had undertaken all of the above expeditions from 1880, the Silvertown Works having manufactured all of the cables therein used. In 1887 he laid the two first Chinese cables between Formosa and the mainland, for the Silvertown Company, they supplying cable, ship and all fittings. In 1888 he was engaged in laying West African cables.

Mr. Rippon, to whose courtesy I am indebted for much of the information here given, is much interested in the "Burke" Cable-Relay, and informed me that he intended to give it a test on the new line at an early date.

Although the line here described is of the utmost value to the business world, it pales in significance before the far-reaching results embraced in the projected extensions of the system which I understand are to be pushed at an early date. Thus, the line is to be prolonged westward from Bermuda to Nassau and Jamaica, and thence to the mainland at Progreso and Vera Cruz, tapping lines to all parts of the U. S., from the south. On the other hand an Eastern prolongation from Bermuda will be laid to the Azores and thence to Lisbon, Portugal, thus making connection with England and Africa.

The Island since 1887 has been provided with a most efficient telephone central system service. The stations are three in number, Somerset, St. George's and Hamilton, the latter being the main station. The subscribers are 152 in number, of whom 114 are in Hamilton. No toll system is used, the rental per year being £6 for business, and £8 for private purposes. There are only three dead head instruments, these being at the government buildings. The system includes 400 miles of wire, with 700 feet of submarine cable; No. 9 wire is employed on the two trunks and No. 12 on short lines. The construction is the same as that commonly employed in the States. All of the construction material, such as poles, insulators, wires, etc., as well as transmitter batteries, has been supplied by The E. S. Greeley & Co., of New York. The central station at Hamilton, although rather small, is neatly fitted up. It is supplied with a Western Electric switchboard for 150 wires, in three sections of 50 each. Two of the sections were supplied by the Tropical American Telephone Co. (who have also furnished the telephones, transmitters, etc.), and the third by the Antwerp Western Electric Co.

The lines are open for business from 6 a. m. to 10 p. m., and from the opening of the main office until the present time there has been no interruption to business. The longest circuit operated is 25 miles. There is no induction trouble on any of the short lines, and on the long 12 mile lines it is so slight as in no way to affect the service, although the telephone wires run for miles parallel with the telegraph, and in some instances on the same poles.

No trouble has been experienced as yet from oxidation of wires, although lines running along the water side on the south coast are beginning to show signs of being attacked. The lines are put up in a most substantial and neat manner, all joints being soldered. The greatest difficulty which has been met with has been in the matter of obtaining grounds, the island being porous coral rock, and no water existing except such as is found in the cemented cisterns, the rain being the only supply for either drinking or washing purposes. As a consequence the curious method resorted to for obtaining a ground is by dropping a coil of wire in the subscriber's cemented cistern, with the exception of the principal street of Hamilton, which has a pole ground wire, the ends connected to plates sunk in the harbor.

The switchboards are never deserted on account of lightning, none of the offices having ever been affected or anything burnt out on them from such cause, and during the three years that the system has been in operation, only six subscribers' coils have been destroyed.

The efficient service, general satisfaction and financial success of the system is entirely due to the ability, zeal and untiring industry of the genial managing superintendent and electrician, Mr. R. A. Ferguson, who not only designed and laid out the system, but personally erected the entire plant. He relates some very amusing episodes of his experience in putting up the lines when assisted by his corps, consisting of three colored men, the first deaf, the second lame and the third blind. Mr. Ferguson is a nephew of Mr. Alexander McCay, the president of the Anglo-American Telegraph Co., and a brother of Mr. James Ferguson, the superintendent of the Municipal Electric Light Co., of Brooklyn, Mr. R. A. Ferguson having left the service of the same company to assume the superintendency and build the Bermuda telephone system.

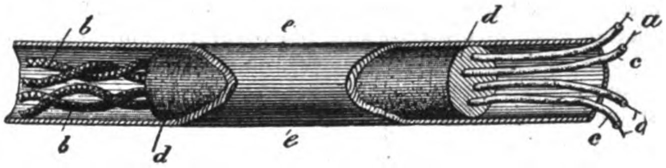
The post-office system of the Island includes a government telegraph having some 11 offices, which are open to public service, although in reality it is a military line. There are 32 miles of No. 8 wire employed in all on double mushroom double-glazed porcelain insulators, with iron bracket pins on cedar poles. The instrument used is the English military sounder with club-handled key, worked on the open circuit system, each office being supplied with 24 old style small sized French Leclanché batteries. Owing either to poor cells or bad insulation the instruments work very faintly. In sending, the operator's sounder is out of circuit and he is dependent upon a curious little upright galvanometer in a cylindrical case upon the sounder base, which acts most sluggishly. The cut-out is rather an amusing sight for Yankee eyes, consisting of a chunk of iron weighing quite ten pounds, which ordinarily rests upon a similar one, although insulated from it, acting normally as a lightning arrester. When it is desired to ground either side of the operating station, the upper block is lifted by a handle and slid down so that its surface rests against the lower block, thus making the ground. Two sets of these are used at each looped station.

No electric lighting is done on the Island. Both of the Quebec Company's steamers the "Trinidad" and "Orinoco" are fitted throughout with incandescents, the system being the "Mather." The work on board has been done in England and has given no trouble whatever since installment. The majority of lamps used are the English Swan. The speed of armature on the "Trinidad" is only 600 revolutions, the light brilliant and steady; the machine is slowed down after 11.30 p. m.

It is now rumored that Bermuda is to have an electric road, and as the scheme will doubtless be carried out, the beautiful Island will be entitled to consider itself as abreast of the times in every electrical art. There is no reason why it should not enjoy all the blessings of electricity in common with the rest of the world, especially in view of its nearness to America.

CANDEE'S IMPROVED CABLE.

It is a well-known fact that underground cables suffer considerably from the entrance of moisture, and even when carefully examined and free from the same at the works are frequently deteriorated by moisture while in the process of laying through careless handling. To avoid this occurrence in cables having paper or fibrous insulation Mr. Willard L. Candee has recently devised a simple method which consists in surrounding the several wires of the cable for a distance of, say, six inches or more from the ends of the sections in a waterproof substance such as okonite, rubber, gutta percha, or the like—filling with such substance the interior of the protective sheath or casing. At the ends of the conductors where the waterproof compound is applied, the fibrous wrapping or envelope is removed, so that the okonite or other material comes into direct contact with the wires and envelops them individually as well as collectively. This is clearly illustrated in the accompanying engraving which shows a number of conductors *a*. Near the end of the cable the several conductors are provided with a coating *c* of waterproof material extending some distance from the ends, and a mass *d* of similar material placed around the entire group of wires, the whole being enclosed by the sheath *e*.

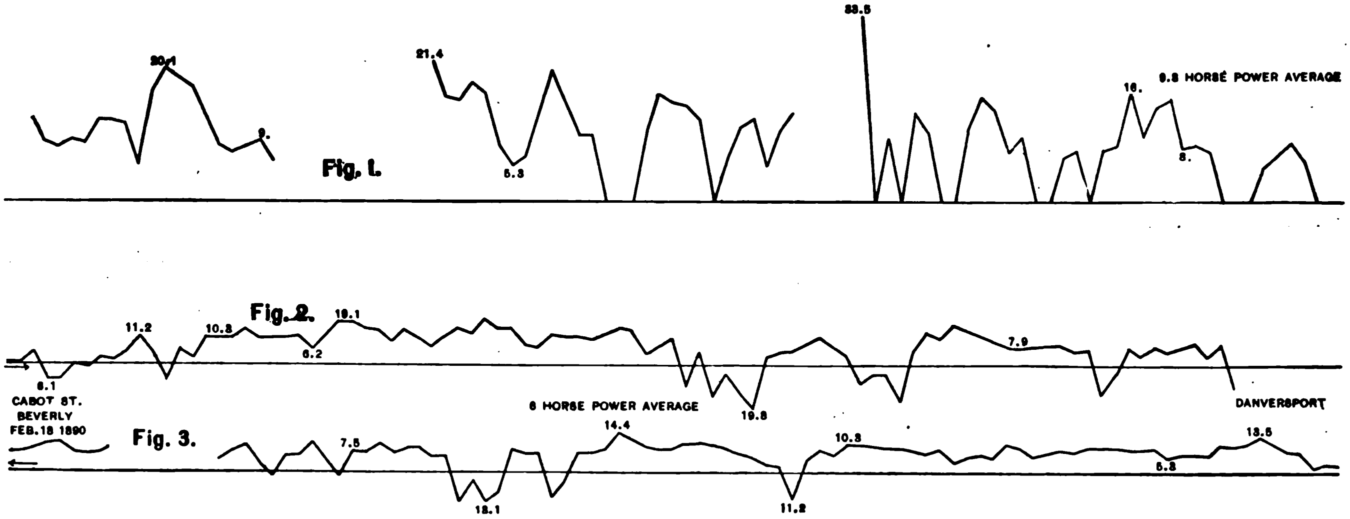


Candee's Improved Cable.

The presence in the cable of a plug or filling of water-repellant substance at intervals effectually prevents access of moisture to such parts of the conductors as are enclosed in the fibrous insulating material, which in conjunction with the exterior case or sheath is claimed to protect the insulation as perfectly as if the conductors were separately incased in a waterproof insulating compound for their entire length.

COMPARATIVE CURVES OF HORSE-POWER CONSUMED ON ELECTRIC RAILWAYS.

We illustrate this week two interesting curves taken on different electric railroads, showing in a graphic method the amount of horse-power necessary to propel electric cars. The upper curve was made from data taken on a car on a level road, using the ordinary overhead single trolley system, with the motor armature geared to the wheels by the ordinary two sets of gears open to the dust gathered from the road. The lower curve was formed from data taken on the Beverly and Danvers Railroad, which is very hilly, on a car fitted with the Union Electric Car Company's system of improved enclosed gearing, and using storage batteries, which, when running down hill, or when stopping the car, charge back into the battery. As will be seen from the first curve, it took about twelve horse-power to start the car at first, the gear being new; and at a certain part of the road consumed 20.1 horse power. The next start took 21.4 horse-power, while the third start took 33.5 horse-power, presumably owing to the gear getting dirty, making an average throughout of 9.8 horse-power over the whole run. In the lower curve on the Beverly road the car was started with from 5 to 10 horse-power, and running at the same speed as in the former test the highest horse-power consumed was 16.1, while where the curve passes below the horizontal or "no-current" line, considerable saving was effected by charging back, as much as 19.8 in one case being returned to the battery. The average horse-power in this case is put down at 6, but as a matter of fact it is about 5.54. The saving over the whole line by charging back is about 14 per cent. The economy in this test, outside of the charging back, is plainly attributable to the improved gearing, which is enclosed in a dust-tight box and runs all the time in oil. These gears have therefore extremely little friction to overcome, and never get clogged up with dirt. The saving in such a case is not at first easily seen, but we think a careful study of the above curves will prove that there is yet much to be improved in the ordinary method of running electric cars, and they will serve as an explanation of the acknowledged and unnecessarily high power which to-day is regularly being consumed on electric railroads.



Electric Railway Power Curves.

INSPECTING THE HALIFAX-BERMUDA CABLE.

Mr. G. G. Ward, the general manager of the Commercial Cable Company, has favored us with a copy of a despatch as follows, received May 22:

"Yesterday a number of gentlemen interested in submarine telegraphy visited the steamer 'Westmeath' (which sails to-day), lying off Greenhithe, for the purpose of inspecting the cable about to be transmitted abroad by the Halifax and Bermudas Cable Company, Limited. The cable, which is 874 miles in length and weighs 2,061 tons, has been manufactured by the Henley Telegraph Company, Limited. When the 'Westmeath' has discharged her burden and the shore ends have been fixed, telegraphic communication will be established between Halifax and the Bermudas, which may form the basis of subsequent developments. The British Government have granted a subsidy of £8,100 to the company, but the post-office authorities have insisted on certain conditions as to the capacity of the cable, all of which requirements have been fulfilled. It is expected communication will be established by June 24th. The tariff will be 8 shillings per word between Halifax and Bermudas, and 4 shillings from England. An interesting feature in connection with the laying of the cable is that it is the first that will cross the Gulf Stream."

WESTERN ELECTRIC PLANT, VIRGINIA HOTEL, CHICAGO.

THE electrical equipment of the larger apartment houses in such cities as New York and Chicago is now, and none too soon, being brought up to the standard of excellence and convenience attainable. In many instances that have come under our notice, the apartment house plant has been "neither fish, flesh, fowl nor good red herring," but an olla podrida of details hardly any of which were designed for the work or were strictly suitable for it. If the owner had wasted his substance in riotous baloonies and pinnacles of carved stone, it is probable that he stinted in the allowance for the electric lighting; if that were not the case, it happened that the work was entrusted to incapable hands. Hence the examples of cheapness and inefficiency have been many and near together, and it is only within a recent period that such plants have approximated the ideal.

We are glad to be able to illustrate in this issue a plant that seems to us to embody a well devised plan, to comprise proper devices and apparatus, to furnish the essentials of safety and comfort, and to present not a few points of novelty and originality. The plant in question is that installed by the Western Electric Company in the McCormick apartment building, or, as it is called, the Virginia Hotel, on Rush and Ohio streets, Chicago. This building was wired for about 3,000 incandescent lights, and the system of mains and feeders is such that an almost absolutely equal potential is obtained at the different distributing points. The connections are made through heavy brass contact pieces placed in pockets lined with asbestos and easily accessible; so that the wiring in any part of the building may be readily cut out for any purpose desired, without interfering in the least with the other circuits or lamps. The branch cutouts are of new design, each being provided with a double pole disconnecting switch. Their construction obviates entirely the use of a screwdriver in replacing fuses, etc., as the clamps for catching the fuses are operated by thumb screws. These cutouts are placed in pockets throughout the building, all of which are at any time readily accessible.

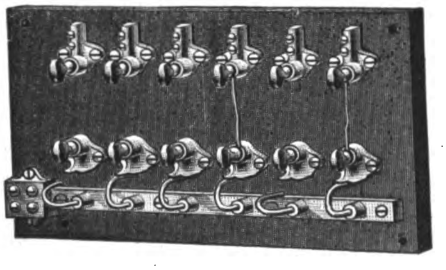


FIG. 5.—WESTERN ELECTRIC MULTIPLE CUTOUT.

In the dynamo room, Fig. 1, the driving power for the Western Electric dynamos, which have been illustrated in this paper in detail, is obtained from two Corliss engines of 150 h. p. and 90 h. p. respectively, which are belted to the countershaft from which the dynamos are driven. The shaft is made in two sections, which may be connected by a positive clutch so that the engines may be run independently or together, as desired. The friction clutch pulleys provided also permit the use of any or all of the dynamos at one time. Rawhide rope gearing is used throughout. The arrangements are extremely simple and flexible.

The four dynamos are of 400 ampere capacity each. The armatures are built up with a single layer of bare copper wire with large commutator segments, and the current is conducted to the switchboard by means of a Patterson underground cable of 425,000 c. m. which contains in its centre, insulated from the main conductors, the wire leading to the dynamo rheostat on the switchboard.

The switchboard, Fig. 2, is of highly polished oak, upon which the various instruments are symmetrically mounted, with an eye to tasteful display of polished brass, copper, etc.

Another feature of the plant is the new multiple cutout board, Fig. 3, in which special attention has been paid to the requirements necessary to insure safety, while at the same time the construction is such as to render it cheap and serviceable. All metal parts are secured to the base by screws passing through the metal into the base; no bolts of any kind being allowed to pass through the base. The bar or strip lying along the lower edge of the board is provided with curved spring switches, Fig. 5, that, when closed, are held firmly in place by a slight indentation or notch upon the lower surface of the contact base. Whenever it is desired to insert a fuse wire or to test a circuit, the spring switches upon both the positive and negative sides can be quickly opened for either purpose. They are manufactured in sizes to suit the varying requirements; the sizes ordinarily used being from four circuits up to fourteen. By reason of its great simplicity and substantial construction this cutout cannot fail to find favor with electrical engineers generally.

The electrical equipment of the Virginia Hotel is not less perfect in the other matters of call bells, tubes, etc. The electric call bell system, in fact, is a decided novelty. Each of the 60 apartments has calls from the private hall to the office, and from the servants' entrance to each kitchen. Every apartment has a call to the office in connection with the tube system. In the office there is a 60-number circular switch, arranged so that each apartment can be called separately, or all at once, as in case of fire. Each of the 60 dining-rooms has calls to the kitchen, with silk cord and spring jack plugs.

In the speaking tube system there are six 2-inch tubes from the tenth story to the office, or one tube for each tier of ten apartments. There are six 2-inch tubes from the tenth story to the janitor's room, or one tube for each tier of ten apartments. There are separate tubes to the main dining-room, kitchens and drug store. In case any one is called for on the city telephone, the clerk in the office can communicate with the party occupying any of the apartments without bothering them to come to the telephone in person.

In each of the two passenger elevators there is a 10-number elevator annunciator, with a push on each floor, connected with a flexible cable to the cab. All the pushes are of Bower-Barff bronze. In the janitor's room there is an annunciator that is operated from each floor by the four freight elevators, so that the janitor can tell at once which floor the call is from.

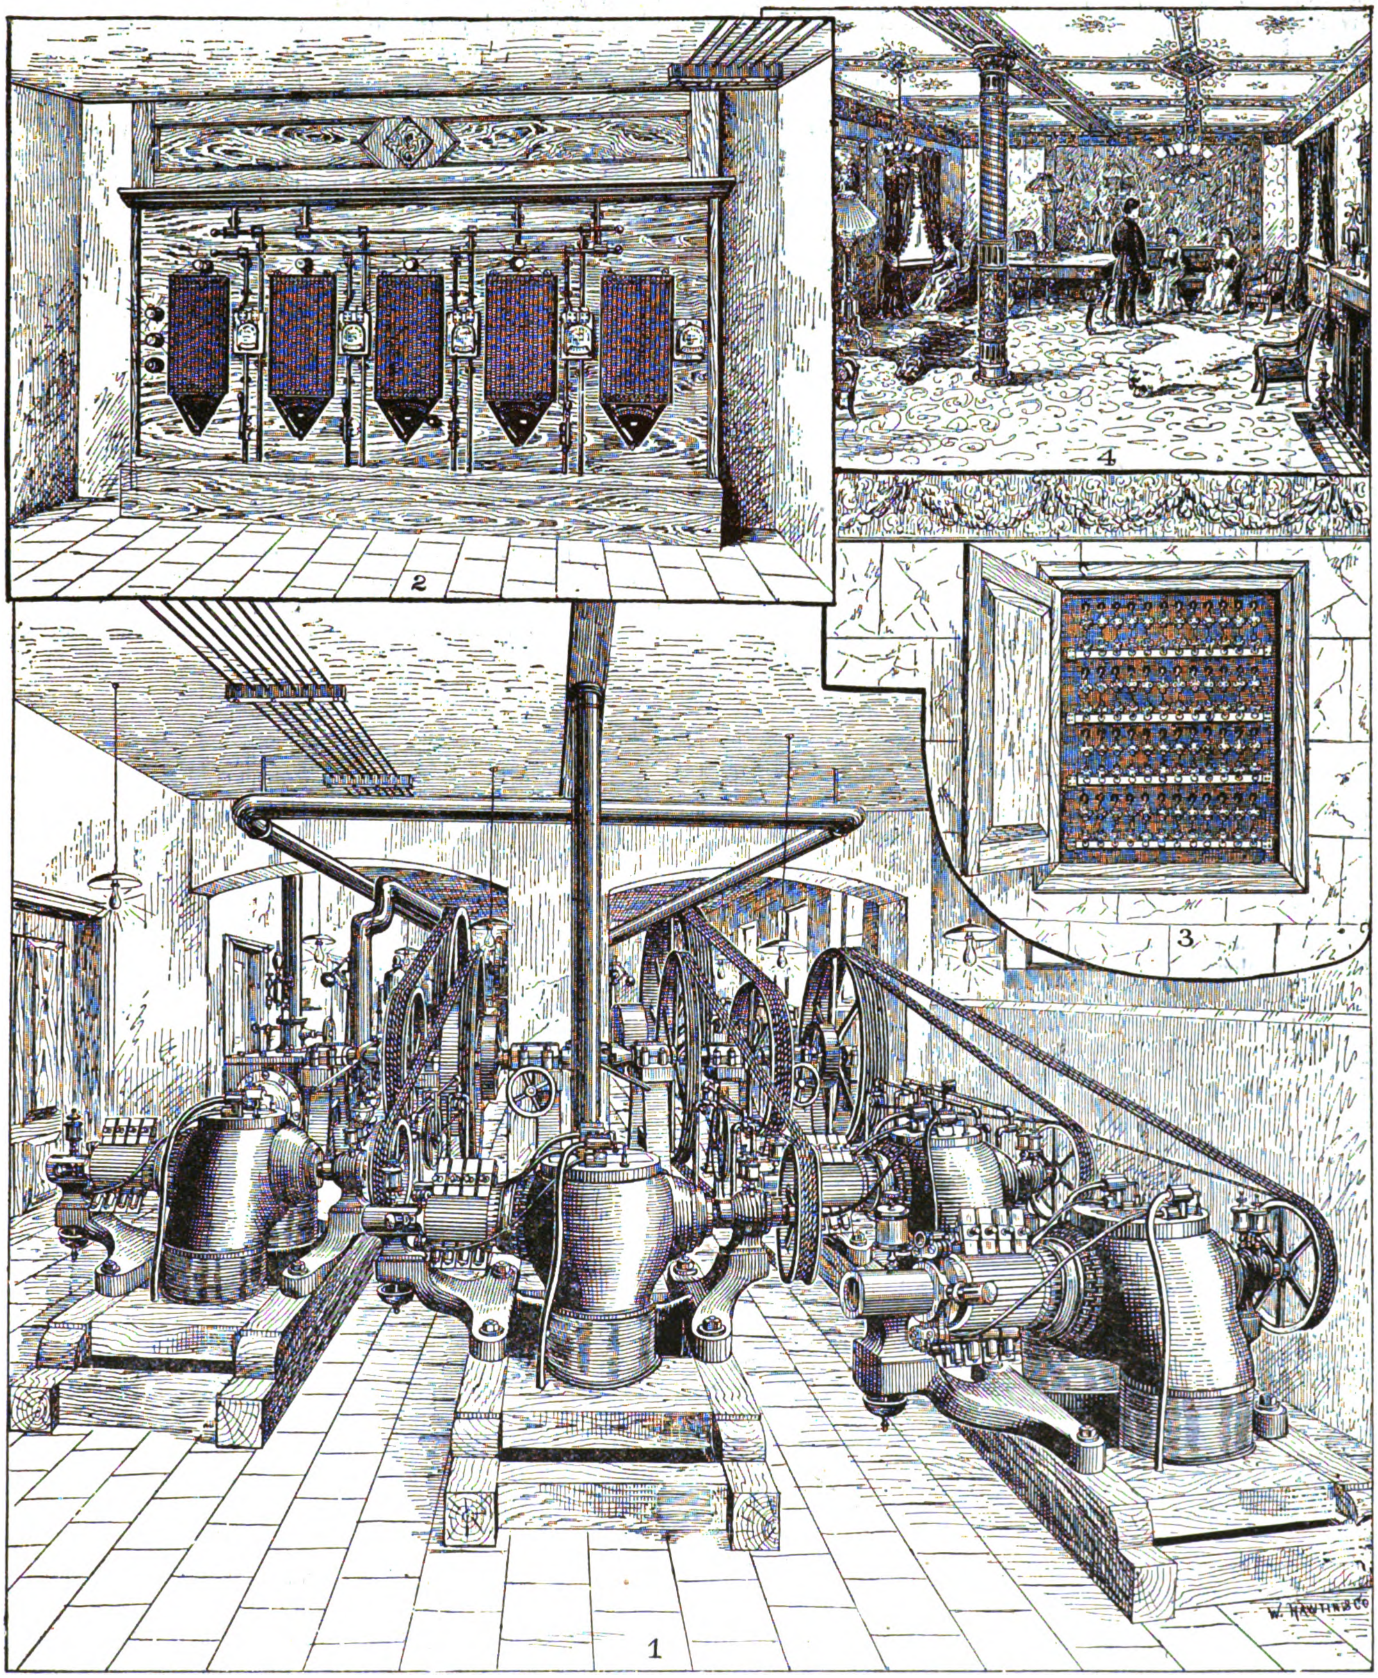
Thus it will be seen electricity has been resorted to for a variety of uses and services; and the results are eminently satisfactory to all dependent upon the plant for their comfort by day or night.

ELECTRIC RAILROADS.

BY R. S. DOBBIE.

ONLY those who are familiar with the struggles that the locomotive endured in its early days can appreciate how gradual was the evolution and slow the growth of the splendid engines of to-day, which seem the very embodiment of perfection. But on looking at the efforts of early locomotive builders we are at once struck by the fearful and wonderful complexity of the motive mechanism. "Sun and planet motions," "grasshopper beams" and a labyrinth of gear-wheels were once in high favor, and it was only the stern law of the survival of the fittest, that has given us the modern locomotive, so elegant in its simplicity, and so perfect in its fulfillment of practical requirements, that we almost think that it will stand unrivaled and unchanged forever.

We will here draw two interesting parallels—first, one between the steam and the electric locomotive. Both of them in the early stage of their existence suffered from gears and cog-wheels; these have disappeared from the steam locomotive and assuredly will do so in the electric locomotive of the future. Second, between two electrical industries, lighting and traction. Development of the former was hindered by the supposition that any shanty was good enough for a dynamo, and in the latter, dirt and mud do not seem to be considered as out of place when in gears and on commutators. Continuing our examination, we find that a few flimsy pieces of painted cotton, upon which the reliability of the entire machine depends may give way to the stresses, mechanical and electrical, that are brought to bear upon them. What would we think of a steam locomotive that virtually de-



Figs. 1, 2, 3 and 4.—Western Electric Plant, Virginia Hotel, Chicago.

pended as to its reliability upon a poor little scrap of cotton? The steam locomotive, however, only slowly attained its present practical development; and so the electric locomotive, despite our advanced knowledge of electrical laws, will only slowly become, as assuredly it will become in the near future, *the* perfect means of locomotion that we hope for and dream about.

Now let us suppose that all the gears, sprockets and chains, and friction wheels now considered so necessary, were swept away and the armature placed directly upon the axle. What would we have to do in order to keep the power the same? In the first place the motor would have to be considerably heavier than the motor of a geared car; but when we consider the weight of the gearing and frames, etc., necessary, it will be found that the discrepancy is not so great as may be imagined. For instance, at a lineal speed of 3,500 feet per minute of the armature, an output of 12 watts per pound weight of motor can be obtained. Now on a street car with wheels about 30 inches in diameter, it is possible to put an armature of 18 inches diameter; this in a 4-pole field will clear the street about 5 inches. Supposing the car to be traveling at 10 miles an hour we would have a lineal armature speed of 520 feet per minute, which is about 1/7 of the speed in armatures of ordinary machines. Now as the speed and weight are both in direct proportion to the power, we must increase the weight (since the speed, by the conditions, is limited) in the above ratio which, more exactly, is as 1 to 6.8. That is, we must make the slow-running armature 6.8 times the weight of one that runs at 6.8 times the lineal speed.

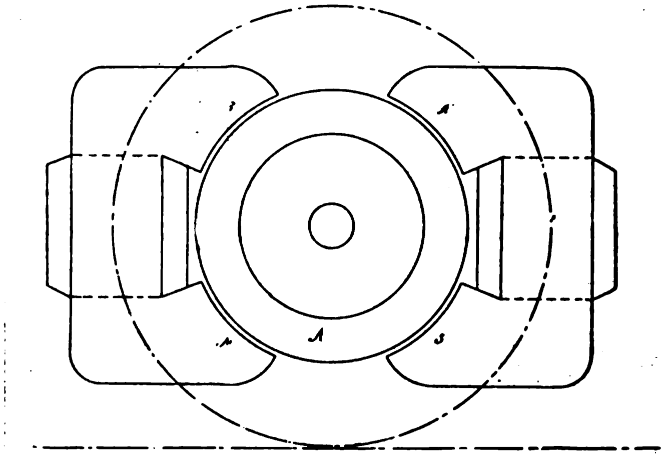


FIG. 2.—DESIGN FOR DIRECT CONNECTED RAILWAY MOTOR.

With say, 10 h. p. on one axle this would require about 4,000 lbs. in the motors; a weight, it is true, above that now usually used; but against this one objection we have many advantages: a reliable and durable motor not easily destroyed by a sudden rush of current, no noise, no gear, and the possibility of speeds far higher than the one taken here.

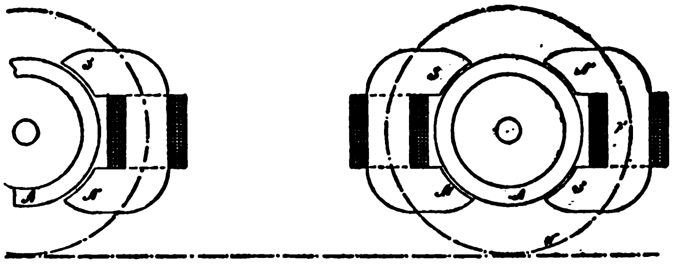

FIG. 1.—DESIGN FOR DIRECT CONNECTED STREET CAR MOTOR.

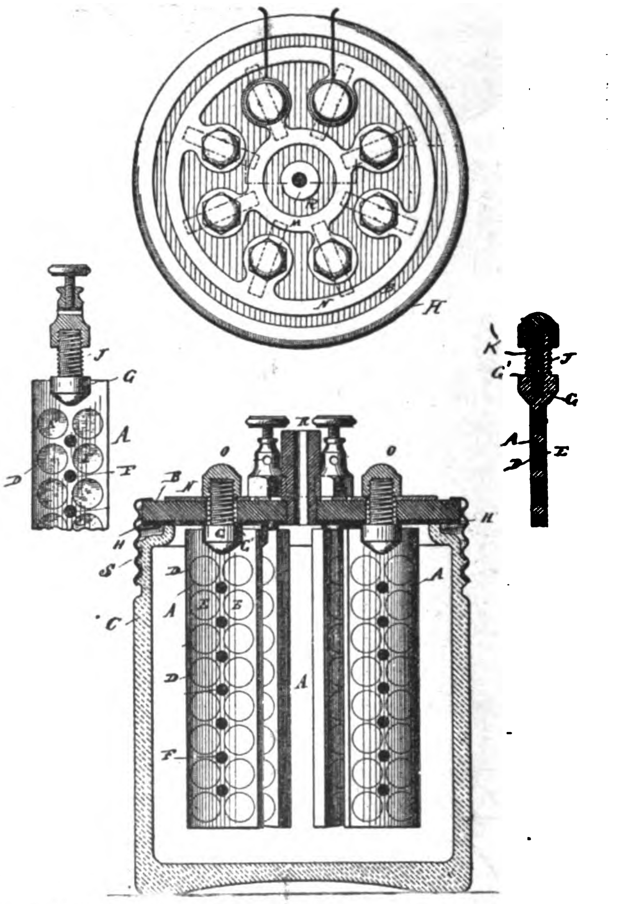
The accompanying illustration, Fig. 1, shows the arrangements for a direct-driving street car with two motors, each of 10 h. p., and designed to run normally at 10 miles an hour. The wheels are 30 inches in diameter, and the axial length of the armature and field magnets is 20 inches. The armature is 18 inches in diameter and revolves in a 4-pole field. Each motor weighs 2 tons, so that their combined weight is 4 tons. While the present design contemplates an axial length of armature and field of only 20 inches, there is sufficient room to increase this to 30 inches if desired.

I have made careful calculation and designs of motors with far more ambitious speed, and find that at speeds of 60 miles an hour with 72 inch wheels and a motor weighing 12 to 14 tons, on one axle a power of 350 to 400 h. p. is possible. A direct-driving high speed electric locomotive on this plan is shown in Fig. 2. The design shows an armature 45 inches in diameter and 30 inches long.

It does not need a prophet to say that no such power or speed is practical with gears, belts or any means of this nature that could be applied.

THE NEVINS SECONDARY BATTERY.

WE illustrate in the accompanying engravings a novel form of storage battery, the invention of Mr. Thomas F. Nevins, of Brooklyn. In this battery the electrodes A are suspended from the insulating cover B, resting on the top of the jar. The electrodes are composed of an alloy of lead and tin, containing not more than thirty parts of tin, and have two vertical rows of apertures D, the edges of which are beveled inward from both faces of the electrode, so as to form pockets for receiving the filling E of the oxide of lead. Additional apertures F are provided between the apertures D to permit of a thorough circulation of the exciting liquid.



FIGS. 1, 2, 3 and 4.—THE NEVINS SECONDARY BATTERY.

Each electrode is provided at its upper end with a projection G, the top of which forms the shoulders G′, which rest against the rubber packing plate H on the under side of the cover. From the projection G′ a threaded stem J projects upward, which contains a threaded core K, of iron, for the purpose of rendering the stem more durable. These stems are passed through apertures in the plate B and through apertures in the lugs of two rings M and N on the upper surface of the cover. The lugs of these rings alternate, as shown, so that the electrodes are alternately held in the lugs of the rings M and N. The ring M is connected with the positive wire and the ring N with the negative. Nuts are screwed on those ends of the stems J projecting above the rings, and by drawing them tight the electrodes are held in place and the rings clamped firmly on the top of the cover. A nut on one lug of the ring M and another nut on one lug of the ring N are provided with a projection through which the conducting wire can be attached.

A vent tube R projects through the top of the cover to permit the escape of gases, and a screw ring S is screwed on the jar, and its flange, pressing on the cover, presses the rubber packing plate H on the top edge of the jar, thus forming a tight joint. The electrodes are arranged radially, as shown in Fig. 1.

The arrangement is such that any electrode that has become destroyed, can be easily removed and another substituted.

NEW PORTABLE TESTING AND RESISTANCE SETS.

We illustrate on this page the new series of portable testing and resistance sets which are being put on the market by Messrs. Queen & Co., the well-known electrical instrument manufacturers of Philadelphia. These sets were all designed in their laboratory, and are intended to meet the requirements of electric light men, telephone line construction, dynamo and motor manufacture and general testing. They will be found adapted to the location of faults in telegraph and electric light lines, determination of armature and field resistance of dynamos and motors and the needs of government and other inspectors as well as to general expert work.

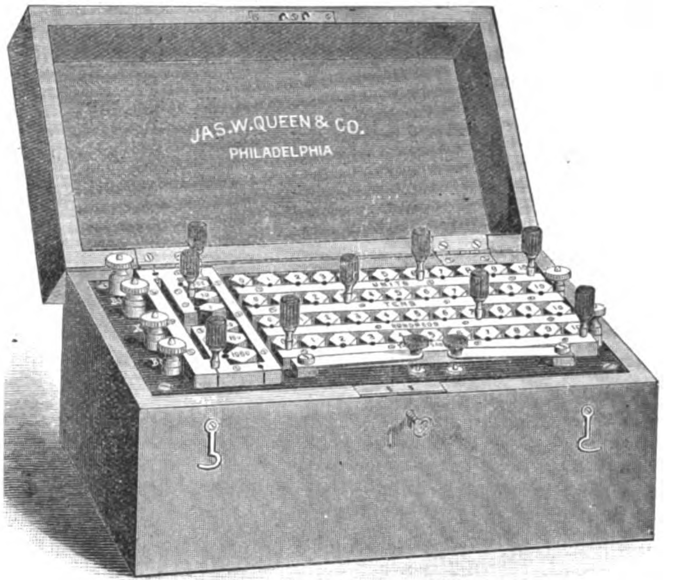


Fig. 2.—New Portable Testing and Resistance Sets.

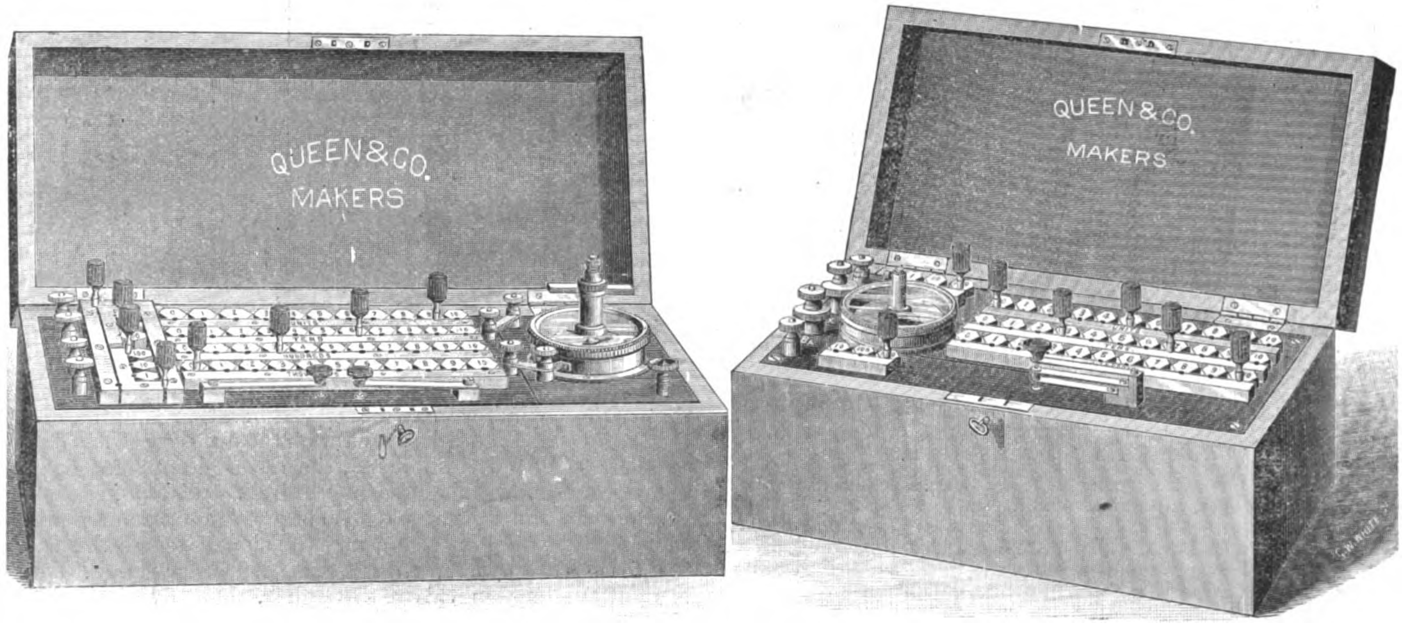


QUEEN & CO.
MAKERS
QUEEN & CO.
MAKERS

Figs. 1 and 3.—New Portable Testing and Resistance Sets.

The set shown in Fig. 1 is the best and most complete of the series, and is recommended for all kinds of work where considerable accuracy is required. The coils in this set are, as shown in the figure, arranged in four rows, each row being made up of ten coils of the same denomination. The blocks in each row are numbered from left to right and from zero to ten, while the longitudinal bars underneath have engraved upon them the denomination of the coils of that row. The connections of the coils are such that but one plug is required for each denomination; by inserting it in any block as many coils of that denomination are thrown in as may be indicated by the particular number engraved upon the block; thus, as the cut represents it, there are in circuit 369 ohms, *i. e.*, no thousands, three hundreds, six tens and nine units. Another special feature of this set is the arrangement of the bridge arms which are seen at the left; these are combined with reversing bars so that the proportional arms may be instantly interchanged, an operation which is absolutely necessary in many special methods. An additional advantage is that but six coils are necessary in the bridge instead of eight as usual, to get the proportion of 1 to 1,000 or 1,000 to 1, thus making the set smaller and more portable. The bridge coils are 1, 10 and 100 on one side and 10, 100 and 1,000 on the other. To effect this reversal, two plugs only have to be changed. The use of this reversing arrangement in testing sets is original with Messrs. Queen & Co., it having never before been employed, we believe, except in the most expensive and elaborate laboratory instruments. The coils are wound of the now famous platinoid wire, which has a very high specific resistance and changing by but .0023 per cent. for each degree Centigrade of temperature variation. They are adjusted by Prof. Wm. A. Anthony to an accuracy of from one-fifth to one-tenth of one per cent. while the bridge arms themselves are adjusted to a still higher degree of accuracy. The galvanometer is a successful adaptation of a laboratory instrument to the needs of portable work and is by far the most sensitive, complete and portable instrument ever combined with a set of this character. The wire is of several hundred ohms resistance and is wound so as to have a maximum effect upon the needle; the needle itself is an astatic one and delicately suspended by a very fine cocoon fibre so that there is practically no resistance to any deflecting force. By means of a very weak controlling magnet sliding upon the suspension tube, the needle can be made almost perfectly astatic and will show an appreciable deflection for currents as small as from one three-thousandth to one five-thousandth of a milliampere; the brass box containing needle and coil is movable about a vertical axis so that the needle can always be brought to zero whatever the position of the box as a whole. The whole galvanometer lifts out of its position in the case and can be used independently or in connection with other apparatus if desired, three leveling screws being provided for leveling when so used. By closing the cover of the box the weight of the needle is automatically taken from the fibre and the latter protected from injury. The battery and galvanometer key are seen in the front of the box and are independent of each other. The whole is mounted up in a polished mahogany box with leather handles and lock and key and measures when complete but 18 in. long by 6½ in. broad. Fig. 2 is a cut of the bridge set without the galvanometer and it is, of course, somewhat shorter. These sets have a range of measurement of from $\frac{1}{1000}$ ohms to 10 megohms.

Fig. 3 shows one of the other sets of the series and is of much the same general character. The coils instead of platinoid are made of German silver and are not quite so accurately adjusted, while the set is without the reversing arrangement found in the one just described. The galvanometer also is fibre suspended, but without the automatic release; for this purpose a small set screw is used which allows the needle to be lowered when not in use; the galvanometer is permanently mounted in the case and is without the control magnet. The keys are combined into the regular double contact form. This set as represented in the cut has but three rows of resistance, viz.: the units, tens and hundreds; it is also made with an additional row of thousands. This set is also made without the galvanometer.

A great number of the sets above described have been sold in all parts of the country and have given great satisfaction. They have been worked upon for some time and improved until they have reached their present satisfactory form. They are now being manufactured in large quantities by Messrs. Queen & Co. and introduced widely throughout the country.

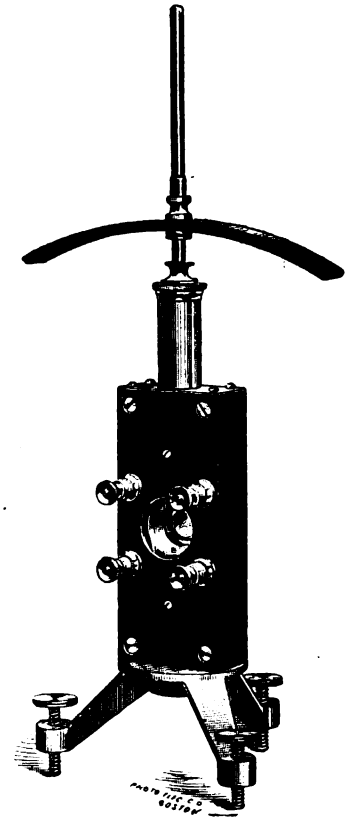
THE SCHARF GAS BATTERY.

The Scharf gas battery consists of a gas-tight vessel, preferably of cylindrical form, capable of holding the gases under very considerable pressure. The idea is to work with two gases in pairs, or with one gas and a liquid—one gas or liquid forming the positive, and the other the negative element in the cell. Among the gases of one class named by Mr. Scharf as suitable for his purpose are hydrogen, water gas, generator gas, coal gas, and all the vapors of the more or less volatile hydrocarbons of mineral oil. In the other class are placed air, oxygen, chlorine, fluorine, and the liquids hydrogen peroxide and nitric acid. Two typical gases for use in this way would be coal gas and oxygen, which would be compressed and stored separately. Each gas is admitted to one side of a carbon diaphragm, or rather, between two adjacent carbon diaphragms, contained in the vessel already described, and the plates of carbon are separated into pairs by alternate spaces filled with a gas and with asbestos saturated with acidulated water. All the intervals of even numbers in the pile would thus contain one gas, and all the others another of opposite electrical condition. In this way a pile of any number of cells might be built up.

A NEW FORM OF REFLECTING GALVANOMETER.

One of the essentials of a good reflecting galvanometer is that the exciting coils should be well insulated and as near to the needle as possible, in order to have the greatest effect upon it. Again, the coils should be well protected from injury and at the same time it should be easy to get at the needle in order to replace a broken fiber. The needle should be light and all parts should be reduced to the simplest form, while the whole should be firm upon its base in order to resist vibration. To meet these requirements, Messrs. E. S. Ritchie & Sons, of Brookline, Mass., have devised the instrument shown in the accompanying engraving.

It consists of a vulcanite case made, practically, in two parts. The exciting coils are held firmly in each part, so that when the pieces are screwed together the inner faces of the coils approach within one tenth of an inch to one another. When the instrument is made with four coils, the distance between the upper and lower pair of coils is sufficient to allow an opening to be made through the case, in order that a glass window may be placed in either side to allow the light to reach the glass mirror on the needle. When only one pair of coils are employed, the opening is placed either above or below the coils as desired. There is a slit through the top of the vulcanite case, which reaches below the centre of the lower coil, and the space around the coils is filled with paraffine so that when the case is closed, there is a slit running lengthwise through it, about five-eighths or three-quarters of an inch laterally, and as wide as the distance between the coils.



New Reflecting Galvanometer.

The coils are made of any desired resistance; each coil may be connected with a pair of pole cups on its own side of the instrument, or the opposite pairs of coils may be connected to one pair of pole cups upon the front of the instrument. In the former case they may be connected either in series or in multiple arc; in the latter case in series only. The coils once in place there should be no need to remove them, and the danger of injury is reduced to a minimum. But should it be desirable to examine the coils for any purpose, the case can be easily unscrewed, one part from the other, and the coils exposed to view.

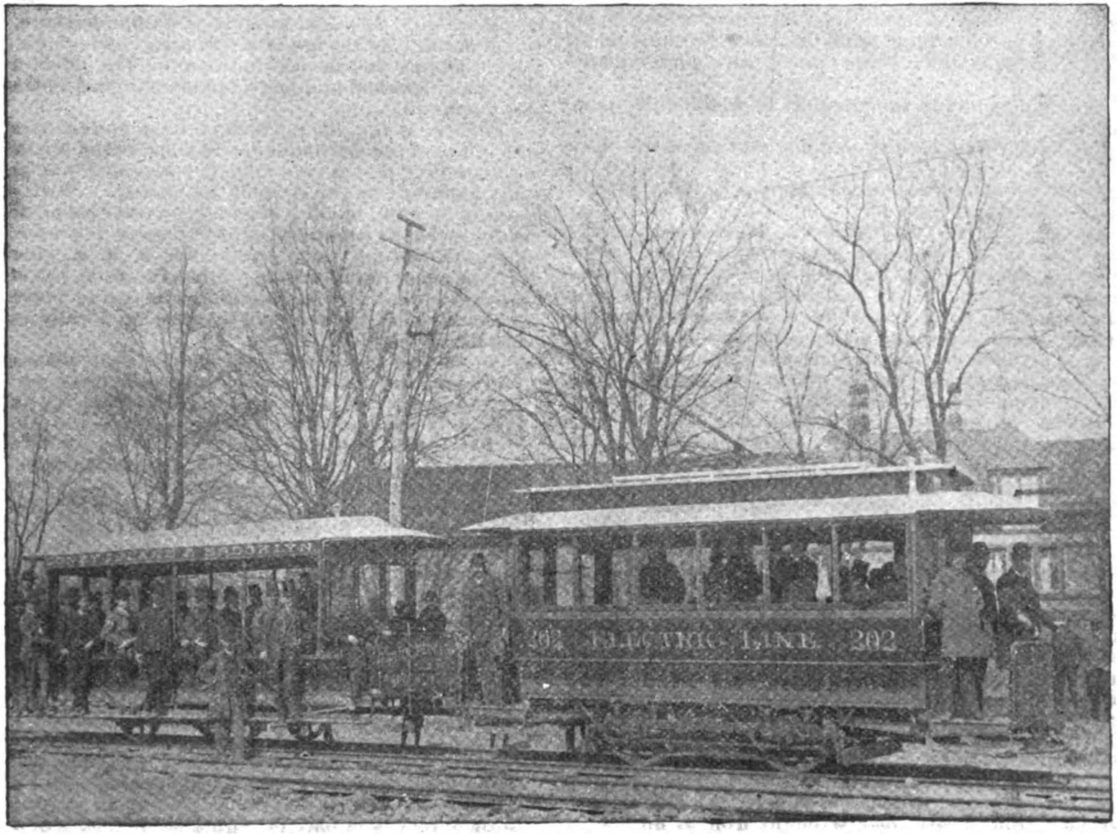
The fibre suspension is outside the vulcanite case. A small pin with a block passes through a marble cap at the top of a sliding tube, which can be raised, or lowered, or turned upon a vertical axis to remove the tension of the fiber. When it is desired to introduce the needle into place it is simply slipped into the slit in the top of the case till the mirror is in the centre of the opening in the side of the case. The fibre is easily fastened to the needle, as the work is done outside the case in the most convenient manner. When it is desired to remove the needle, the case is simply inverted, and it slides out without trouble, the tube carrying the supporting pin being removed at the same time. Two needles are made for the instrument, one of which is dead beat, and the other for use when the throw of the needle is used, as in insulation testing. The fibre suspension is covered by the adjusting magnet support. The whole case is fixed to a brass tripod with leveling screws, by thumb-screws, so that when it is desirable to use it as a portable instrument, the rod carrying the magnet is removed from the case and that in turn from the brass tripod, so that it can be packed into a very small space. As the exciting coils are entirely protected from injury in handling, this instrument is especially adapted for the use of students, or where a portable instrument is needed by the electrical engineer. The instrument as ordinarily made will give a deflection of one millimetre with the scale at one metre distance, with an E. M. F. of one volt through a resistance of 1,100 megohms.

Robbing Western Union.—It is reported from South Dakota that large defalcations have been discovered there by the Western Union Telegraph Company, reaching, in fact, a sum of from $50,000 to $75,000. Another discovery is that certain officials have been working in the interests of the lottery scheme, and that Northern Pacific officials have been assisting in the little game. In other words, telegrams favorable to the lottery project have been expedited, those unfavorable have been held back; and the secrets of their opponents have been revealed to the lottery ring.

ELECTRIC ROAD AT CONEY ISLAND N. Y.

The equipment of the Brooklyn and Coney Island Railroad has just been completed by the Thomson-Houston Electric Company, on its well-known system. This road consists of sixteen miles of track which is equipped with central pole double bracket suspension, the trolley wire being suspended from poles placed between the tracks 125 feet apart, and provided with ornamental iron brackets. The construction is done in the most thorough and workmanlike manner, and the general artistic appearance of the line has caused much favorable comment.

The car equipment consists of twelve double motor cars, and others will soon be added. The power station is provided with the necessary boilers for supplying steam to three 200 h. p. engines, and the usual heaters, pumps, etc. The electrical apparatus consists of six 100 h. p. Thomson-Houston railway generators, of the four pole type, and switchboard with the usual fittings. A part of the station is used as a car house and is provided with eight tracks with pits underneath, thus rendering the cleaning and repair work an easy matter.



Brooklyn and Coney Island Electric Railway.

A TELEGRAPH LINE IN AFRICA.

It would undoubtedly be possible, says the New York *Sun* to deliver in a few hours a cablegram sent from New York to Europe, down the African coast to Senegambia, up the Senegal River to Kayes, and through the forests to Seguiri on the Upper Niger, hundreds of miles from the coast, and for a long distance through a savage region in which there is not a single white station. In that region one sees no telegraph poles save those that nature planted, for the wire is fastened high up in the trees of the interminable forest. All the branches and foliage that would be likely to break the wire or interfere with its efficiency are carefully trimmed away. Probably the longest stretch of telegraph wire in the world through a wholly uninhabited region is that extending clear through Australia from south to north. It crosses the great interior wilderness which explorers so long tried in vain to traverse, though they were stimulated to their best exertions by the splendid offer of $50,000 which the Australian Governments pledged themselves to pay to the first man who crossed the continent from south to north.

AUTOMATIC ELECTRIC WELDING MACHINES.[1]

BY HERMANN LEMP, JR.

AMONG the latest achievements in electrotechnics, stands prominently Prof. Thomson's electric welding process. The broad underlying principle has so often been described and exhibited by its able discoverer and others, that to repeat it now would be imposing upon your patience. The evolution of a new process and its reduction to practice for commercial purposes, especially if the leading elements of its working are novel in themselves, must necessarily open a vast field for investigation. Such is the case with electric welding, and with a view of showing the commercial apparatus of to-day, it will be necessary for me to state the electrical and mechanical requirements which led to its construction.

The reason for which machines have been invented has been for the purpose of reproducing faithfully and constantly a set of conditions necessary to obtain a certain result. When the conditions in any case are few and the product simple, generally one design of machine will be sufficient. With an increased number of conditions, however, the complexity of the apparatus increases rapidly and demands, in many cases, a subdivision into different processes to be executed by separate machinery. What constitutes skill in a workman, for instance, is the ability to co-ordinately reproduce a number of operations or movements; to be, in other words, a perfect machine, or to produce the same result even if other conditions than those previously contemplated should arise.

To secure uniform results in the practice of a difficult operation, there are two ways possible.

1. To employ skilled help for the complex portion of the work alone.
2. To substitute for the more complex portion of the operation one more readily controlled.

The ordinary welding process requires the greatest skill at the hands of the blacksmith for heating the metals to the proper temperature and at the right spot, while preventing the accumulation of cinder or scale. While skill may be successful with metals of high melting points and low conductivity for heat, easily fusible metals and especially good conductors baffle all attempts as long as an exterior heating source is employed.

The electric welding process has, as you know, not only made it possible that operators not particularly skilled in the art of blacksmithing can produce good substantial welds, but has created an art equally adaptable to all metals and combinations of metals.

The following are all the metals, alloys and combinations so far actually welded with success by the Thomson process:

Metals.—Wrought iron, cast copper, antimony, aluminum, manganese, cast iron, lead, cobalt, silver, magnesium, malleable iron, tin, nickel, platinum, wrought copper, zinc, bismuth, gold (pure).

Alloys.—Various grades of tool steel, various grades of mild steel, steel castings, chrome steel, Musshet steel, stub steel, crescent steel, bessemer steel, cast brass, gun metal, brass composition, fuse metal, type metal, solder metal, german silver, aluminum alloyed with iron, aluminum brass, aluminum bronze, phosphor bronze, silicon bronze, coin silver, various grades of gold.

Combinations.—Copper to brass, copper to wrought iron, copper to german silver, copper to gold, copper to silver, brass to wrought iron, brass to cast iron, tin to zinc, tin to brass, brass to german silver, brass to tin, brass to mild steel, wrought iron to cast iron, wrought iron to cast steel, wrought iron to mild steel, wrought iron to tool steel, gold to german silver, gold to silver, gold to platinum, silver to platinum, wrought iron to Musshet steel, wrought iron to stub steel, wrought iron to crescent steel, wrought iron to cast brass, wrought iron to german silver, wrought iron to nickel, tin to lead.

But Prof. Thomson was not satisfied with this progress made above ordinary welding, and early recognized the importance of a machine in which all conditions for successful operations are mechanically controlled to produce uniform results, and which would be rapid working and require little or no attendance.

Such machines, now known as automatic welding machines, have proved to be of special importance in connection with easily fusible metals, enabling the successful welding of aluminum, silicon and aluminum bronze, which, even with the electric process, require considerable skill.

Before entering into a detailed description of the automatic welder a few general data on welding will be in order.

The Thomson process of electric welding can be, and has been, worked by means of continuous or alternating currents; secondary batteries or multipolar machines may be and have been used. There are such conditions as transportability, absence of motive power, situation in continuous distribution district, etc., which may make it advisable to use the continuous current. The alternating currents have so far been the best adapted to produce economically of large volume at low E. M. F. They are easily and economically controlled, allow of being distributed at high pressure with small conductors and of being reduced to working pressure wherever needed. They have, however, another beneficial effect, which is of importance in all welds of large sections.

It is a well-known fact amongst manufacturers of incandescent lamp filaments of large section that the inner portion in a filament is apt to be overheated. In treating filaments as used in the now commercial series lamp, in a hydro-carbon atmosphere, the writer attempted at one time to produce an extra good quality of carbon by starting with an extremely thin base .004 inch thick and obtaining a filament, 90 to 95 per cent. of which consisted of hard, gray, lustrous carbon. He thought to extend this process to the manufacture of arc light carbons and even produced pencils of about ¼ inch diameter. What was his surprise, however, to find that although the lustrous surface presented at all times a dense gray structure, the core lost this character after a certain thickness of carbon had been deposited. In fact, a number of concentric layers could be discovered from the innermost graphite to the dense gray semi-crystalline at the outside.

This action can, to my mind, only be attributed to the overheating of the carbon particles in the inside. A similar action takes place in a bar of iron if heated by an electric current. The surface exposed to radiation will be at a lower temperature than the core. It is true that the heating of the metal will increase its resistance and thus tend to equalize the temperature, but not enough in all cases. By the use of alternating currents we gain, however, an assistance in the self-induction. The effect of the latter is especially marked and has a tendency to concentrate the heat on the surface.

If there is any place which receives more current than another the effect of the self-induction is emphasized by the fact that the surrounding part is cool and its permeability is greater than the part traversed by the surplus of current. With very large, and especially wide, metal pieces the unevenness of distribution may be remedied by approaching iron masses to create at a given spot a greater self-induction or counter E. M. F., thus diverting the current from that section. Prof. Thomson has early recognized the importance of, and patented, a device to prevent the heating of the metal at a given spot by creating locally increased self-induction or magnetic effects.

In view of this experiment almost daily witnessed by us, it is interesting to note the paper controversy between parties disputing the priority of a device which is to produce exactly the opposite result with, however, the same means and conditions.

Two methods of distribution are in use, the direct and the indirect. In the former, an alternating current dynamo is used, having two windings on the armature, one of which furnishes currents rendered continuous by a commutator to excite the field magnets, and is controlled by switch and rheostat; the other consisting of a single turn of heavy copper cable furbishes the welding currents, which is led through collector and brushes to movable copper clamps suitable to receive and guide the welding specimens during the operation.

In some other forms the field magnet is the movable part, in which case no heavy currents have to be carried through collector and brushes. No direct welders are built at present for currents larger than 4,000 amperes.

The indirect method of distribution is almost exclusively used to-day. It consists in its simplest form of one alternating current dynamo, self or separately excited, and one welder which is a transformer with the necessary clamping and operating appliances. The self-exciting dynamos used are from 1,000 to 20,000 watts output, and may be regulated by means of a reactive coil to give a varying E. M. F. never exceeding 300 volts.

They are substantially built to withstand sudden strains, have self-oiling bearings; the brushes are designed never to be moved and are perfectly sparkless, requiring no other attendance but cleanliness.

The winding on the transformer being set once for all, variation in the E. M. F. has to be obtained either by varying by hand the initial E. M. F. of the dynamo or by exciting a dynamo to the lowest potential required, it being so compounded as to give with the maximum work the increased E. M. F.; or finally to maintain a constant E. M. F. at the dynamo under all loads and vary the E. M. F. at the transformer by interposing a variable resistance, or preferably a self-inductive resistance. The transformer itself may be built so as to give a different ratio of conversion, either by moving the primary and secondary relatively to each other or by shunting lines of force by means of an iron bridge between primary and secondary, or by altering the number of turns in primary or secondary by a switch.

When a single plant is used, viz., one dynamo and one welder, it is the dynamo, generally, which, if separately excited, is regulated by means of a rheostat in the exciter circuit, or by a reactive coil in series with the exciting coil on the armature if self-excited. The diagram, Fig. 1, shows the connections used with a separately excited machine. The only thing different from similar installations is the break switch which is operated by a foot treadle and automatically opens the circuit when the foot pressure is removed.

---

[1] A paper read before the General Meeting of the American Institute of Electrical Engineers, Boston, May 21st, 1890.

This prevents any mishaps when operated by uninitiated persons, as all action ceases when one leaves the apparatus. The primary voltage never exceeds 300 volts with 100 alternations, or 50 complete cycles per second. Nothing but the very best insulation is used in the primary wiring. It is deemed necessary to protect users of the apparatus not only against any shocks, but even against the scare of one, and we recommend the permanent grounding of the secondary which in welding apparatus is virtually the table and pressure devices.

CONNECTIONS FOR TYPE D. DYNAMO AND INDIRECT WELDER.

Fig. 3

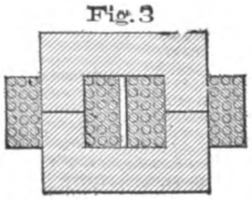

Fig. 4

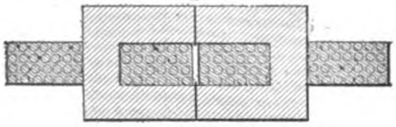

Automatic Electric Welding.

Fig. 2 shows the connections used for a self-excited composite dynamo, which has two windings on the armature, a longer main and shorter exciting coil. Both are wound in the same direction, and currents generated therein pass in multiple, connected through the shunted field magnet; after this through line No. 2, controlled by a break switch, and then split, one returning through reactive coil and line 3, the other through welder and line 1 to their respective windings. The exciting effects of each circuit add themselves. The reactive coil is conveniently placed near the welder. Dynamo is regulated from the minimum to 300 volts and is excited anew for each weld.

For some work which requires to be done at great speed, the second method is resorted to; that is, to keep the field constantly excited by fixing a variable reactive coil in a given position, just enough to produce about 150 volts, the lowest E. M. F. required. The proportion of the field magnets, the E. M. F. of exciting coil and the resistance of a shunt to the field are such as to produce an overcompounding of 100 per cent. in this case, with the largest current in the primary.

This method of regulation is very neat, as it is absolutely automatic, responds quickly, the field of the dynamo not requiring to "build" every time from residual magnetism alone. We sometimes call it "cubic compounding," as it produces a constant heating effect for variable cross sections and variable lengths as well. With this modification, the wiring of diagram, Fig. 4, is slightly altered, the break switch breaking only the main circuit, leaving the exciting circuit permanently closed.

Automatic Electric Welding.

The methods so far described are only used when a single welding machine is to be operated. It was early recognized that if the process is at all to be used on a commercial basis, the generating of the necessary current at least should be limited to as few machines as possible. It required, in other words, a dynamo giving a nearly constant E. M. F. of sufficient capacity to feed a number of welders while maintaining for each absolute independence.

Since all welding for a long while to come will probably be operated in isolated plants, the dynamo is to be placed in the hands of an engineer, generally not an expert in electrical matters, and has, therefore, to be easily attended and free from all the little faults and kinks which are at present the sole consolation of the dynamo tender. One of its prime requirements is close automatic regulation under all loads.

Constant potential, self-regulating dynamos are manufactured in various sizes and are self-exciting up to 30,000 watts output. Dynamos with larger output are separately excited, but also self-regulating. The methods employed to obtain regulations are novel and will form the subject of another paper at some future date. I would simply state that either constant potential, or a percental increase with load can be obtained and that the regulation will respond even if the load consists of self-inductive translating devices. I lay some stress on the regulation of the dynamo for the reason that the generators are not to be placed in the hands of special attendants as in case of a central station, but have to deliver their currents under constant pressure whatever may be the conditions of work they are subjected to; even an automatic regulator would hardly be able to follow the rapid variation of load.

The following conditions influence the perfection of the work and are variable with different materials and sizes:

1. Projection of the abutted pieces in the path of the current.

2. E. M. F. of welding current as controlling the strength of current flowing.

3. End pressure applied to force the abutting ends into each other at welding heat.

4. Interruption of current at proper time.

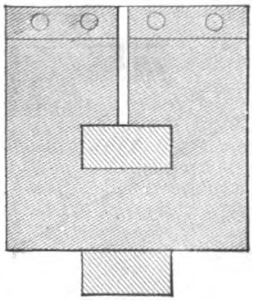
1. The projection of the abutted pieces varies with the diameter. It has been found that for copper, a projection of twice the diameter for each clamp gives the most economical results. With steel and iron, the most economical projection equals the diameter and is one and one-half times the latter for brass.

The projections sensibly affect the energy required and the most economical one depends upon the heat conducting properties and specific resistance of the specimens. Accordingly, highly conducting bodies require longer projections; highly resistant ones, short projections. Conductors of larger and smaller diameters may be welded by giving to each its respective projection. In the same manner wires of different materials may be joined to each other.

It is easily understood that since unequal projections on different sized conductors produce the proper heating of both at their junction, equal projection of equal sized conductors will be required. All other conditions aside, it is important to keep the projection for a given size and material constant.

2. The E. M. F. required depends upon the projection and the resistance of the material to be welded. For large cross sections the specific self-induction plays an important role, and indirectly, the shape of the specimen.

Fig. 9



AUTOMATIC ELECTRIC WELDING.

Another factor affecting the E. M. F. is the resistance between clamps and material and the resistance of copper conductors. The E. M. F. required for iron and steel is nearly double that for copper and would be four times if equal projection were used for both.

A certain drop of E. M. F. will be found from the clamps to the specimens. This drop is rather low on material having naturally bright surfaces, as, for instance, copper, brass, german silver, tin or even cold rolled iron and steel. For a large class of work, however, especially in carriage hardware, the surfaces to be used for contact have a light scale left after passing through the rolls, which has either to be removed by grinding or filing, or to be overcome by the E. M. F. of the current. In a good many cases the introduction of a special process of cleaning is deemed to be more expensive than to use a little extra power to work through the scale.

3. For uniformity of result the end pressure required to press the abutting specimens into each other at welding heat is of more importance than any of the former agencies; this is, in fact, the one which controls and rectifies any inaccuracies in the former conditions. If the pressure necessary for a given size and material is used, the weld cannot be performed until the metal has acquired the necessary plasticity to yield to the pressure. If for one reason or another, the E. M. F. and, consequently, the current should have been too strong, the time necessary for welding alone is affected, and in this case shortened. The bars will, however, be united at the same temperature and with the same force, whatever may have been the time required to bring about the necessary plasticity. The pressure will in some respects influence the heat by forcing the metals into each other at either higher or lower temperature, and by so doing cause the action to be interrupted at an earlier or later period as may be required.

The pressure required varies with the material and is approximately 1,800 lbs. per square inch for steel; 1,200 lbs. per square inch for iron; 600 lbs. per square inch for copper; it varies also with the area of cross section as indicated by its being expressed in a function with the surface as one of the factors.

4. The interruption of the current as soon as the weld is completed is important for all easily fusible metals. When two copper wires are welded together the welded portion being increased in cross section owing to the end pressure, if the current is not interrupted a large portion of the conductor on either side of the weld, including the latter, become heated and will melt and be torn asunder before any pressure device could follow and bridge the gap over.

The current should, therefore, be interrupted as soon as the weld is completed. It is also sometimes required that the parts to be welded should be of a certain predetermined length, in which case the interruption of the current as soon as the allowable distance has been reached is essential.

All these conditions are maintained constant in the automatic welder before us, which is the first commercial type of its kind. This welder is not entirely automatic in the strict sense of the word. The degree of automatic action has to be considered separately for each individual object. This machine contains, however, the leading features as covered by Professor Thomson's patent, June 26, 1888, No. 385,022, with a few improvements in mechanical construction.

The capacity of the machine is, nominally, copper wire, No. 6 to No. 17 A. G. It will, however, weld larger and smaller sizes. It weighs 130 pounds complete; the secondary is one solid copper casting of a cross section resembling a hollow, square box with one of the sides removed. This casting is firmly screwed to an iron table. A saw cut at right angles to the plane of loop creates the two poles, one insulated from the table, the other constituting a V-shaped bearing suitable to receive a sliding clamping device. The hollow part of the secondary receives the primary coil which is separately wound in a form and insulated with special care. Two U-shaped laminated iron cores embrace the primary and secondary.

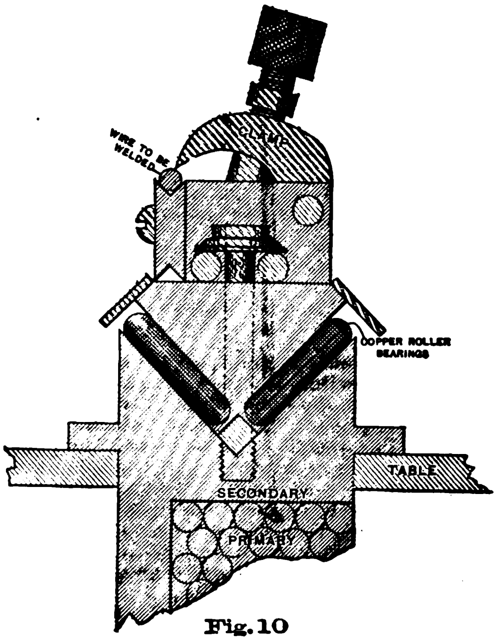


Fig. 10

AUTOMATIC ELECTRIC WELDING.

It has been found that the best form of transformer is the one in which the primary and secondary coils are co-axially placed in an iron core, so as to oblige all lines of force generated by the former to cut through the latter. If the two windings are placed side by side on an iron core or on opposite legs, as shown in Fig. 3, there is a tendency to form consequent poles at the point where the two windings meet, due to the leakage of lines of force. The leakage will depend upon the distance between the two legs, and upon the length of the magnetic circuit. It has been purposely increased and turned to advantage by Prof. Thomson, for obtaining constant current in the secondary while the primary is supplied with constant E. M. F., as shown in Fig. 4. When, however, constant E. M. F. in the secondary is required, it is important that this leakage should be decreased to a minimum.

Various forms of secondary may be employed to work consistent with the above principle. A few of these are shown in diagrams Nos. 5, 6, 7 and 8, in which cases the secondary is preferably a solid copper casting. The forms shown in Figs. 8 and 9, however, permit hard rolled copper plates to be used. For mechanical reasons and convenience, the forms shown in Figs. 5 and 6 are mostly used and actual experience shows practically no leakage. This construction permits of removing the primary without disturbing the secondary in the least. It also gives the least possible self-induction for a given cross section.

It is often stated that when large quantities of alternating currents have to be conveyed through copper conductors, it is important to have the same laminated or subdivided in smaller conductors to reduce self-induction. This may be true to a certain extent. The shape of the cross section is, however, far more important than the lamination. An experimental compound conductor consisting of a number of flat copper ribbons in parallel showed a self-induction of *three* when the ribbons were closely packed, of *two* when separated into two parts, and *one* when spread open like a fan. The explanation for this was given to the Institute last year by Prof. Thomson when he showed the self-induction to depend mostly upon the length of the lines of force surrounding a conductor when traversed by intermittent or alternating currents.

Returning to the subject before us we find that the pole which is insulated from the table constitutes the stationary clamp. The uninsulated pole, which is considerably larger, has on its upper side a long V-shaped groove parallel with the axis of the secondary, Fig. 10. A movable copper block, also V-shaped, fits in the bearing and can be slid forwards and backwards in the same.

This movable block carries the second clamp. The current necessary for welding has to pass through this sliding contact. The welding of small copper wire or any other easily fusible metal, is a very difficult thing if special apparatus is not used. The current required is very large, several hundred amperes for wire not larger than No. 17 A. G.

The metal when it reaches welding heat readily melts away and has to be followed by the movable clamp so as to prevent the breaking of the circuit. This latter action, when it occurs, is so violent that a special device is necessary to prevent injury to the coil in case of such a rupture. The moving clamp, in order to follow the softening of the metal has therefore to have as little friction as possible and yet has to make a good contact to carry the heavy currents. The clamp is furthermore required to move in true guides so as to abut the small conductors with their axes in line. The heating necessarily brought about when rapid and continuous welding is done must not interfere with the bearing and cause the carriage to stick through expansion.

All these conditions have been complied with in using the V bearings, the carriage being held down in contact by means of a heavy spring and a number of copper rollers being interposed between the carriage and the bearing. Fig. 10. The copper rollers are simple short pieces of ¼ inch hard rolled copper wire rounded at the ends. There are sixteen altogether, eight towards the front and eight towards the back of carriage, equally distributed on both sides of the bearing.

A stationary rod at the apex of the bearing prevents the interference of the two rows of rollers. Between the two sets of rollers in front and in back, a bolt passes, applying the spring pressure which forces the carriage into contact with the bearing. A pressure of 40 pounds may be employed, and yet the carriage will move freely. These sixteen rollers have to transmit a current of approximately 3,000 amperes. They absorb about 20 per cent. of the total energy, which loss is, however, fully balanced by the reliability and simplicity of the device. This loss is moreover only on the maximum sizes and becomes insignificant on small work.

An adjustable coiled spring pulls the sliding clamp towards the stationary one. In front and pivoted on a lever is the distance gauge which may be inserted between the two clamps. This gauge carries on a central disk a number of steel pins of varying lengths, but equal projection on either side of the disk. These projections, if inserted between the two clamps, give the necessary distance required for a given size wire, the disk against which the wires are abutted insuring equal projection of both ends to be joined. On the back of the apparatus a switch is located in the primary circuit, which is normally held open by a spring. By moving the handle to the right, the primary will be closed and the switch locked by a little catch underneath the table. A pin fastened to the movable clamp will lift the catch and release the switch, thus opening the circuit.

An intermediate lever between catch and pin operated by a sliding rule, which serves also as an index, permits of varying the point of cut-off, which has to be in a certain relation to the distance between the clamps. The position of cut-off, tension of spring, distance between clamps corresponding to each other, are marked with the same figure, which is also inscribed on a wire gauge fastened to the welder. By inserting a wire into the gauge, the number read will give the necessary adjustments at once.

If by imprudence, the switch should be moved to the right, while no stock is inserted and the clamps come in contact with each other, the switch cannot be locked and the fuse in the primary will be blown, without, however, causing any damage.

The insertion of the distance gauge between the clamps locks the switch so that the primary can only be closed after withdrawing the gauge.

The operation is as follows :

1. The wires to be welded are gauged.
2. The distance gauge and cut-off are set to correspond with the number on the gauge.
3. The movable clamp is moved to the right and the gauge inserted.
4. Both wires are securely clamped, care being taken to abut the ends squarely against the disk.
5. The gauge is withdrawn.
6. The switch is moved to the right.
7. The reactive coil is moved towards a position of minimum reaction, and restored to maximum after the weld has been completed.
8. The clamps are opened and the weld removed, after which the operation can be repeated.

If a good many welds of the same sized material are to be made, the reactive coil may once for all be set in a given position and the switch alone be operated. Welds made with the automatic machine have attained a uniformity not obtainable with the most skilled operators working without it. In fact, small, easily fusible wires can scarcely be welded with certainty with ordinary apparatus. For aluminum, especially, the automatic apparatus is needed.

The reactive device used in connection with welders is of the type recently described by Prof. Thomson, in which a case is made to more or less cover the primary, the self-induction of which is to be altered. To obtain a still larger range, the windings of the primary can be coupled in series, or multiple series, or in multiple by a switch in the base of the coil.

As mentioned before, the welding of easily fusible metals may sometimes cause a rupture of the secondary circuit, which, owing to its violence and volume of energy may cause a burn-out of the primary if not guarded against. This danger is not very great in the automatic machine, since the end pressure does not depend upon the attention of the operator. A special device is, however, used as an extra precaution against all emergencies.

Breaking a high tension circuit rapidly is not easily done. An arc generally follows the break and this lengthens the time of the rupture. If the voltage of the circuit to be broken is so low that over the slightest distance an arc cannot follow, the break will be instantaneous. This is the case with the secondary circuit of a welding transformer. The voltage being ordinarily only one volt, would, even if increased ten-fold, not be able to maintain an arc. However, multiplied in the primary it will cause E. M. F. sufficient to pierce through the insulation as ordinarily used. This action is similar to that of a Ruhmkorff coil in which the interrupter is caused to break under oil or water. This discharge is taken care of by a special apparatus, the description of which I reserve also for another communication to the Institute.

While the machine before us is only one type embodying the principal features contained in all, others have been manufactured or are in process of construction in which the automatic character has been carried out even further, as in the welding of rings and chains. I am not permitted to give a detailed account of these latter at the present time, but would say that the present model in its first form, is able to produce 250 feet of chain in a day without any attendance to speak of, the plain wire being fed into the machine at one end and the complete chain coming out at the other.

The automatic principle is, however, not confined to small conductors. We have welders with 40,000 watts output, capable of welding 1 inch copper or 2 inch iron, constructed and working daily on that plan. The projections are determined by adjustable stops, the pressure, the most important of all, is hydraulic, and regulated by an automatic reducing valve, the exhaust being used for cooling the clamps at the same time. The primary is controlled by adjustable reactive coils from a constant potential circuit and is interrupted at the proper time by the clamps. While not all machines are to-day operated on this plan, I am convinced that the evolution of the welding process tends in that direction and that the welding in future will be in the full sense of the word a purely mechanical operation. This cherished idea of Prof. Thomson's, uttered a few years ago, has well been borne out by the experience gained in actual operation on a commercial basis.

RESIDUAL DISCHARGE IN CONDENSERS.

The phenomenon of residual discharge which occurs with condensers has sometimes been attributed to an actual penetration of the electricity into the substance of the dielectric. M. Bouty, in a recent investigation of the subject, has experimented on mica condensers formed of very thin plates. It was assumed that the positive and negative electricities, soaking into the dielectric from the electrodes, would meet and neutralize each other if the plates were sufficiently thin. A constant current would therefore pass under the influence of a steady electromotive force, and the dielectric would behave like a conductor. It is a deduction from theory that for condensers having the same dielectric the product of the capacity and dielectric resistance should be constant. The experiments of M. Bouty appear, however, to disprove this law. The experiments seems to show that the conduction of dielectrics is due solely to extraneous surface leakage arising from imperfect insulation of the electrodes or to flaws in the material. M. Bouty accounts for the phenomenon of residual discharge, which causes the variations in the current on first applying the battery, to progressive change in specific inductive capacity during that time. It, however, appears easier to follow Maxwell in accounting for the separate effects by the simple assumption of a heterogeneous dielectric. In view of the great practical importance of insulators, it is desirable that these experiments should be repeated, for the results are at variance with recognized views.

THE ELECTRIC CURRENT AS A TRACTION INCREASER.

BY ELIAS E. RIES.

WITHIN the past three or four months a number of articles have been published in THE ELECTRICAL ENGINEER purporting to show, some theoretically and others by experiment, that the passage of an electric current between a driving-wheel and rail could have no effect in increasing the traction or coefficient of friction between the two surfaces in contact, and that if the current had any influence at all upon the friction it could only act to reduce the traction, instead of increasing it.

As the writer was probably the first to call general attention to the importance of increasing tractive adhesion by the direct action of the electric current, and the first to point out the laws bearing upon this subject, as determined by experiments made by him several years ago for that purpose, it may be thought proper that he should reply to these articles. It was hoped by him, however, that what he had already stated would have been sufficient to enable the intelligent reader to judge for himself as to the correctness of the conclusions arrived at by the authors of the articles referred to, but it seems that some of the writers have themselves lost sight of, if they ever understood, the fundamental principles involved in this method of increasing traction, and it, therefore, becomes necessary to describe more specifically the conditions under which this increased traction is obtained, and to briefly point out why the experiments in question failed to show what was expected of them.

It appears to have been taken for granted by many persons, probably because the phenomenon of increased traction was first observed in the operation of electric railway motors, that the mere use of the track rails as the return conductor in an electric railway system is all that is necessary in order to insure increased adhesion between the motor wheels and the rails. This is by no means the case, as the result is entirely dependent upon the nature of the current employed and the circumstances under which the current is permitted to act. As a matter of fact, the conditions existing on single trolley railways, as at present operated, are not such as to be favorable to the production of increased traction, and although a certain amount of increased adhesion occasionally manifests itself, it is not such as to be relied upon with any regularity or certainty, and is due, as will hereinafter appear, to causes entirely different from those that produce increased traction in cases where a local or independent traction circuit moving with the vehicle is employed, such as embodied in the method of electrically increasing traction patented by the writer.

In my original paper upon this subject, read before the American Association for the Advancement of Science, in August, 1887,[1] the underlying principles and conditions governing the production of increased friction by the action of the electric current were set forth for the first time in the following paragraph :—

"Before entering into a description of the means by which this result is produced and how it is proposed to apply this method practically to railway and other purposes, it may be well to give a general outline of what has so far been determined. These experiments have shown that the coefficient of friction between two conducting surfaces is very much increased by the passage therethrough of an electric current of *low electromotive force and large volume*, and this is especially noticeable between two *rolling* surfaces in peripheral contact with each other, or between a rolling and a stationary surface, as in the case of a driving wheel running upon a railway rail. This effect increases with the *number of amperes of current* following through the circuit of which the two surfaces form part, and does not materially depend upon the electromotive force so long as the latter is sufficient to overcome the electrical resistance of the circuit. This increase in frictional adhesion is principally noticeable in *iron and steel*, although present in other metallic bodies, and is due to a molecular change in the conducting substances at their point of contact (which is also the point of greatest electrical resistance in the circuit), *caused by the heat developed at that point*. * * * The most economical and efficient results have been obtained by the employment of a transformed alternating current of *extremely low electromotive force but of very large volume or quantity*, this latter being *variable at will* so as to obtain different degrees of frictional resistance."

The correctness of the principles originally set forth in the above paragraph have been repeatedly substantiated by subsequent experiments, and it will be seen therefrom that in order to produce increased traction by the direct action of the electric current, the following conditions must be observed :

1. The current must be of such volume as to produce an appreciable amount of heat at the point or points in contact.

2. The electromotive force must be as low as possible. Experiments made by the writer have shown that a high electromotive force has a tendency to *diminish* friction, especially if the pressure between the surfaces in contact is a moderate one.

3. The metals in contact should be of iron or steel, as these have the requisite electrical resistance at their contact surfaces and are of such molecular structure as to permit of a close and intimate union between them under the influence of the current.

4. One or both the metals should preferably roll upon the surface of the other. This is desirable in the first place in order to economize current by concentrating the heating effect upon as narrow a line of contact as possible. Furthermore, a rolling motion, where the line of contact moves progressively and uniformly along both surfaces, as in the case of a wheel and rail, where the contact is continually established at a new point before the old is broken, requires less current to produce a given tractive effect than does a case of sliding friction, where the surfaces move at different rates of speed and are never in fixed relation to each other for an appreciable length of time.

Let us now see whether or not these conditions have been fulfilled by those who have endeavored to show that the electric current is incapable of increasing tractive adhesion. We will then look at the matter from a more practical standpoint, and show what the electric current *has* done and is capable of doing in this direction, when properly applied.

In THE ELECTRICAL ENGINEER for May 7, 1890, Prof. Lucien I. Blake, of Kansas, describes and illustrates a number of experiments stated to have been made for the purpose of determining whether an electric current would, as stated, increase the friction between a wheel and rail in electric railways. Four different experiments are described, not one of which even *approaches* the conditions met with in railway practice. In two of these experiments such metals as platinum immersed in flowing murcury, and a brass bar sliding upon brass rails were employed! The flat surfaces in frictional contact "varied from 1⅛ to 3 square inches," an amount several times greater than the combined effective area of contact of four ordinary railway car wheels, while the current sent through these surfaces was several times less than that ordinarily used in railway practice, being but 1 ampere and 10 amperes respectively! The two remaining experiments illustrated a case of rolling or sliding friction in which the current used was presumably the same as in the first experiment—"varying from 0 to 1 ampere." In short, these experiments seem to have been devised for the express purpose of showing "how *not* to do it," since Prof. Blake himself admits, in concluding, that "the currents employed were not sufficient to produce heating at the surfaces of contact," and adds (probably after having accidentally demonstrated the fact) that "such heating would doubtless produce an increase of the coefficient of friction."

In THE ELECTRICAL ENGINEER for April 9, 1890, Mr. O. T. Crosby describes some dynamometer tests also tending to show that no increase in traction occurs. These tests were made by him with an ordinary single trolley motor car, and consisted in first returning the motor-operating current through the wheels and rails in the usual manner, and then repeating the experiments with the wheels out of circuit. The current employed was varied from 0 to 42 amperes during the experiments, and the electromotive force, though not stated, was probably 500 volts. Unfortunately the capacity of the dynamometer at Mr. Crosby's disposal was less than that needed to register the ordinary tractive effort of the car on a level track, and he found it necessary to jack up one end of the car so as "to *skid* only one pair of wheels, and to relieve these of part of their weight." It will be apparent from what has been said that the conditions under which these tests were made were not only unfavorable to the production of increased traction, but were of such a nature as to bring about the very opposite result.

There seems to be an impression among many persons that the increased traction, if present, must be due in some way to magnetic action. This view of the matter has been taken by Mr. Nelson W. Perry, of Cincinnati, in a communication published in the New York *Electrical Review* of March 1, 1890, in an endeavor to show that no appreciable increase in traction can result from the direct passage of an electric current from wheel to rail or *vice versa*, because there would not be sufficient *attractive* force produced. It was further stated that the passage of current in this manner could only result in a repellant action between the metals in contact, the author citing, among other things, the action of the electro-motograph in support of his views, and in general denying that increased traction could result by reason of *any* change, molecular or otherwise, caused in the surface of the metals by the action of an electric current, notwithstanding the fact that elsewhere in his communication he admits having witnessed an experimental demonstration in which the current *did* have the effect which he endeavors to prove it *could not* have. It is needless to state that there is not the slightest basis for any of the theoretical conclusions referred to, which in the case of this writer we will charitably assume arise entirely from a misconception of the real actions to which the increased adhesion is due.

We will now consider the part the current plays in the production of increased traction. It has already been said that this phenomena is directly due to the *heating effect* of the current upon the metals at their point of contact. A certain slight magnetic effect is necessarily also present, but this is so small in the case under consideration that it does not enter to any appreciable extent into the result, and may therefore be neglected. This heating produces a molecular change in the surfaces of the metals which causes a variation in the coefficient of friction between them, but the nature of this variation and the manner in which the increased adhesion is produced depends upon the nature of the metals and the degree of heat developed at their points of contact. As an illustration of this, it may be stated that a moderate current of sufficient strength to cause increased adhesion between iron or steel surfaces will have a lubricating effect upon brass contacts and cause a diminution of the normal friction between them, although with a sufficiently large current the friction between the latter may be increased.

---

[1] See *Railroad Gazette*, Aug. 19, 1887; *Electrical World*, Aug. 27, 1887; *Scientific American Supplement*, Dec. 10, 1887.

Experiments have shown that in the case of iron and steel a comparatively slight amount of heat will serve to increase the friction to an appreciable extent, this being due to a slight expansion and elevation of the metal at one or both sides of the normal line of contact. This action is practically instantaneous, the heating effect taking place on the *surfaces* of the metals long before the bodies of the latter have had time to become sensibly warm. That the particular effect here referred to is due principally, if not entirely, to the heat, and not to the current directly, is proven by experiments made by the writer with a small electric railway model, in which the increased friction continued an appreciable length of time *after* the traction current had been cut off, the wheels of the motor car having been previously heated by the current so as to retain for a time a portion of the heat imparted to them.

The friction between driving wheels and rails is considerably increased beyond this point, however, by increasing the current strength so as to produce a still greater local heating of the metals at the point of contact, and this is the method preferred by the writer, and most economically carried out by the use of a closed traction-increasing circuit of low resistance, moving with the vehicle and including the driving wheels and that portion only of the track rails that lie between them; when the current strength is sufficiently augmented the increased traction becomes due to an *incipient welding* of the metals along the line of contact. This action leaves no permanent trace upon the wheels or rails, nor is there any appreciable increase in rolling resistance noticeable. The writer has even increased the current strength so as to produce an actual weld between the wheels and rails, without material injury to either of the rolling surfaces; in some experiments on overcoming inertia the metals separating again on the line of the weld, due to the film of oxide between them. By the employment of converted alternating current of high periodicity with respect to its volume, the heating effect may be confined to the surface of the rails without penetrating into the interior. As a rule the amount of current needed to produce a given increase in traction is found to be proportionate to the area of the surfaces in contact and, to a certain extent, to the speed of the driving wheels. The conditions under which increased traction is called for in practice are favorable to the use of a comparatively small amount of electrical energy for this purpose, since it is only in starting heavy loads and in ascending grades, when the rate of speed is much below the normal, that increased adhesion is usually required.

The writer has recently had occasion to construct a small electric motor car and track with which a number of important features bearing upon this subject have been satisfactorily illustrated. This model is still in existence, and may be seen in successful operation at the writer's office, room 27,* Chamber of Commerce Building, Baltimore, at any time. The apparatus in question consists of a small electric railway car having two driving axles insulated from each other and operated by a small electric motor supplied with current through flexible conductors in circuit with a single cell of secondary battery. The driving axles are arranged so that one of several sets of iron or steel driving wheels of different diameters can be placed thereon. The traction-increasing current is derived from an independent source and is varied according to the requirements of the experiment in hand. This current, by means of a second pair of flexible conductors connecting with binding posts on the car, is sent from the forward to the rear driving axles through the intervening driving wheels and track rails, although the arrangement is such that it can be sent directly from one rail to the other across the wheels and axles, thus enabling the terminals of the traction-circuit conductors to be attached to the rails at one end of the track, instead of being carried by the motor. The weight upon the driving wheels without extra load is about three pounds.

With this apparatus, employing a continuous traction-increasing current derived from one cell of secondary battery, the tractive effect of the motor car was increased considerably over 150 per cent., the car climbing grades of 30 feet to the hundred with perfect ease against the pressure of a spring tending to pull it backward, whereas with the same propelling current flowing through the motor, but with the traction circuit open, the car remained spinning at the bottom of a 10 per cent. grade, not having sufficient tractive adhesion to lift its own weight. Upon again closing the tractive circuit the car instantly regained its grip upon the rails and shot up the incline like a flash until its further upward progress was stopped by the distended spring and cord that secured the car to a post at the lower end of the track and prevented it from running over the top of the incline. No sparking, flashing or other visible indication that current was passing between the wheels and rails could be observed in this experiment.

There is no mistaking the action of the motor, or the important part the current plays in increasing tractive adhesion. If, while the car is ascending a steep grade, the traction-increasing circuit be opened and then again closed, the car will commence to slip backward and continue doing so with accelerated speed until the moment the circuit is completed, whereupon its descent will be almost instantly checked, and it will promptly proceed to mount the grade again as if nothing had happened.

Among other things it was shown by this apparatus, as originally predicted, that the traction is not diminished, but (compared with mechanical traction under like conditions) enormously increased when the rails are wet or slippery. The presence of water on the rails seemed to make no difference in traction while the current was passing. With the rails and wheel tires thoroughly *oiled* the car remained stationary, with the motor running at the bottom of a 6 per cent. grade. One end of the track was then elevated to form a 25 per cent. grade, and on closing the traction circuit the little car actually climbed up the slippery track as far as the spring would permit without a single idle revolution of the driving wheels!

On increasing the traction current by connecting a second cell in series with the first so as to produce a perceptible and progressive incipient welding between one or more of the wheels and rails, the tractive pull of the car on a level track, as measured by a standard spring balance dynamometer, was rapidly increased from 6 ounces, the normal pull without traction current, to 31 ounces with the current, *an increase of over* 500 *per cent!* Were it not for the fact that at this point the load and the tractive adhesion exceeded the maximum power developed by the little motor, the increased traction actually registered would have been much greater. With the same current passing between the wheels and rails the car performed the remarkable feat of ascending, without any slip, a 50 *per cent. grade, part of which was coated with oil!* This experiment has since been witnessed by a number of prominent electricians and engineers, who expressed themselves as astonished beyond measure at the wonderful increase in friction obtained, and the comparatively small amount of electrical energy required to produce it.[2]

In order to determine some of the conditions bearing upon the application of this system of increasing traction to ordinary railway train service, a series of preliminary experiments upon a large scale were made by the writer nearly a year ago with a locomotive on the Philadelphia and Reading Railroad.

These tests were made with a locomotive selected by the railroad company, a "consolidated" engine weighing 111,000 pounds (one of the heaviest and most powerful in the service of the road), of which 98,000 pounds, or nearly 50 tons, was distributed over *eight* coupled driving wheels measuring about 54 inches in diameter. The traction current was generated by a special low tension, direct-connected steam-driven dynamo mounted upon the locomotive, one terminal being connected by a heavy stranded copper cable with the forward and rear pairs of drivers respectively, which were insulated from the frame of the locomotive by special insulated brasses at the boxes and journals, the opposite terminal of the dynamo being connected with the two intermediate pairs of drivers. This arrangement was adopted to avoid interruption in the circuit at the rail joints, which on this road, as is usually the case elsewhere, were not directly opposite on both rails, but overlapped. The average resistance of the traction circuit with the locomotive at rest measured less than one two-hundredths of an ohm, practically all of which was located at the respective points of contact between the wheels and rails. The current could be varied during the different tests by varying the field strength or speed of the dynamo, or both, from about 500 amperes to the maximum output of the machine.

The first experiment was made on a substantially level track, and consisted in coupling the locomotive to a train of twelve loaded coal cars and setting the brakes on these so that the engine could not possibly start the train without continuous slipping, several unsuccessful attempts to do so being made. The dynamo was then started up and the performance repeated with *entire success*, the train being brought under full headway from a position of rest without a single slip of the wheels. This was repeated a number of times, the engineer being instructed to do his utmost to make the wheels slip while the current was flowing, as by suddenly throwing open the throttle to its widest extent with the eccentric lever in its foremost notch, etc.; but without effect. It was estimated that the load moved by the engine during this test was equivalent to a train of 110 cars.

---

[2] It appears that the presence of water or oil upon the rails, as shown by these experiments, has a tendency to confine the passing current to a much narrower and smaller area of contact between the wheels and rails, thereby enabling a given current to produce a much greater heating effect at the very point where it is wanted. In other words, the weight upon the drivers is sufficient to "squeeze out" whatever oil may lie directly under the mathematical line of contact, but the film of oil or water at either side of this line offers sufficient resistance to the low tension current to confine the passage of the traction current to the exceedingly narrow portion of the wheel surface in actual metallic contact with the rail. Thus, what has always been a decided disadvantage to mechanical traction is, or may be, utilized in a most important manner in increasing traction electrically.—E. E. R.

A number of subsequent tests were made on the Frackville branch of the P. & R. R. R., upon a steep mountain grade seven miles in length, averaging 185 feet to the mile, and containing numerous sharp and difficult curves. Regular service runs were made over this grade both with and without the current, under conditions as nearly alike as the traffic over the road would permit, with entirely satisfactory results. The official records of the tests show that in nearly every instance the use of the current produced a decided increase in the tractive capacity of the locomotive, and prevented the enormous wear and tear, loss of time and consumption of coal occasioned by the excessive slipping that took place when natural adhesion alone was relied upon. On one occasion the time required to ascend the grade with a load slightly in excess of that usually carried, was, without current, 55 minutes, as against 29 minutes with the current flowing, under exactly similar conditions. The amount of coal consumed on the last named trip was *less than one-half* of that used in the trip without current, by reason of the absence of the rapid exhaust and loss of power consequent upon the slipping of the drivers.

These tests, though made under some disadvantages, were so satisfactory that they are now being continued under conditions and auspices more favorable for carrying out this work. It is estimated that the tractive adhesion of steam locomotives can by this method be increased 25 per cent., and even more in special cases, or where the construction of the locomotive is such as to permit it to utilize a greater increase. This not only means that four locomotives will be enabled to do the work that now requires five, but that longer and heavier trains can be moved, better time made, steeper grades overcome, quicker stops effected, inertia more promptly overcome and, more fuel saved than by the present methods, and what is perhaps of the greatest importance, without any material increase in the weight upon the drivers or roadbed. These and other advantages are by no means limited to steam locomotion, but apply to electric railway operation with equal or even greater force.

The question will now probably be asked: "Are the conditions existing on electric railways employing the rails as a return conductor for the propelling current such as render this current a factor in increasing the traction, and if so, to what extent?" Before answering this question let us briefly review these conditions.

In the early days of electric railways the potential difference under which the motors were operated was very small, in some cases as low as 120 volts, and the currents correspondingly large. The track rails were usually of some obsolete light weight T pattern that have done more or less service on some suburban horse railway line, and the bearing surface of which was curved to such an extent that the driving wheel contact amounted barely to a point. Under these circumstances, a useful amount of increased traction was obtainable, especially in starting the motor on a grade, when the flow of current was unusually heavy. On "single trolley" railways as at present operated, under a potential difference of 500 volts, the currents employed are not sufficiently large to produce increased traction by the *direct heating* of the metals in contact, except when, as sometimes happens, the tread of the wheel runs upon an exceedingly narrow portion of the rail surface, and even this effect is largely, if not entirely, counteracted by the high electromotive force of the current.

However, a certain amount of increased traction may be, and often is, *indirectly* produced by the current on single trolley railways. This occurs when the contact between the wheels and rails is temporarily interrupted at more or less frequent intervals by particles of sand or other foreign matter on the rails, thereby giving rise to small electric arcs and producing the "flashing" noticed under these conditions. The heat generated by these arcs is in many cases sufficient to soften the metal and to cause an actual fusing or welding action between the surfaces of the wheels and rails when they again meet beyond the grain of sand or other obstruction, the latter being sometimes vitrefied or decomposed by the arc or embedded in the heated metal. As the car moves forward, the arc, which is originally sprung behind the obstruction, advances along the wheel and rail to a point in front of it, and the points of the metal thus heated, approaching each other, unite under pressure and almost instantly cool, extinguishing the arc in so doing and producing a more or less perfect weld at the point of contact, to which the increased traction is due. The welds thus formed are again broken, during the separation of the wheel and rail surfaces on their line of least resistance, which is generally that corresponding to the original surfaces because of the film of oxide and other impurities usually found between the fused metals, and which in most instances prevents a homogeneous weld.

From this it will be seen that notwithstanding the small volume of the current on single trolley railways, an appreciable amount of increased traction may manifest itself by reason of the comparatively high electromotive force producing a slight change in the action of the current. The use, for example, of a moderate amount of sand in conjunction with the current on grades of more than usual steepness will serve to increase the adhesion both mechanically and electrically to a certain extent, but this plan is not nearly as efficient, economical, or reliable, leaving out for the present the question of its advisability, as the employment of a current of lower voltage and larger volume for the direct and uniform heating of the contact surfaces.

It may be stated in general that while it is possible to obtain a certain appreciable percentage of increased traction on electric railways in which the propelling current is returned through the wheels and track rails, and while in some few cases a slight increase is necessarily present as a function of the propelling current, yet the conditions under which such roads are usually operated are not favorable to the production of such increased traction. Numerous experiments made by the writer have shown that the most satisfactory and economical method of employing the electric current as a traction-increaser, whether on steam or electric railways, is to establish an independent low resistance circuit, including the driving wheels and so much of the track rails as lie between them, and to charge this circuit with a low-tension traction current, capable of producing the desired heating effect. As this circuit is entirely independent of, even though it may be derived from, the motive power of the vehicle, the amount of increased traction can be regulated without regard to the speed of the motor, and can also be used on down grades to assist the brakes in stopping the car. The increase in the adhesion on single trolley roads under the most favorable conditions is limited by the low heating effect of the propelling current, whereas in the case of the independent traction circuit there is practically *no* limit to the amount of increased adhesion obtainable, since this adhesion may be increased to such an extent as to actually weld or "freeze" the driving wheels to the rails.

PUBLIC CONTROL OF ELECTRIC LIGHTING.[1]

BY VICTOR ROSEWATER, JOHNS HOPKINS UNIVERSITY.

THE question of municipal control of public electric lighting involves two opposing interests. The individual, as a stockholder in a corporation disposing of its product to a city, is influenced by a policy different from that of the individual in his capacity as a citizen and a taxpayer. The former seeks to obtain the greatest possible return upon his investment; the latter is interested in keeping the cost of street illumination at its lowest limit. For the general public, then, the most important part of the discussion must revolve about the point of comparative cost under the two systems.

The business of electric lighting is now usually considered as monopolistic in its nature, and only to be engaged in after a franchise has been secured from a local authority. This privilege immediately assumes a market value, and if the plant be sold the franchise becomes an article of commerce. Why should a community grant out a privilege, valuable to others, when that privilege has the same, if not a greater, value to itself? The statistics published by the Common Council of Scranton, Pa., show that in ninety-one cities, illuminated by private electric lighting corporations, the average annual price for each arc light is $105.13, while in seventeen cities supplying their own service, the average annual cost is but $52.12½ per lamp. The same economic phenomena may be illustrated by comparing the cost of illumination to the taxpayers of two neighboring cities in Massachusetts. Danvers and Franklin have each 1,200 candle-power lamps burning every dark night until midnight. Danvers, owning its own plant, pays annually $45.37 per light; Franklin pays a corporation $80 per light yearly.

But one of the defenders of monopoly, in criticising these figures, says:

"The cost price given for all-night lighting in nine cities owning their own plants averages $53.80 per lamp per year. It is ordinarily estimated that one arc light, requiring about forty-five volts and nine amperes, consumes one horse-power at the engine. In an article in the Buffalo *Express*, April 3d, it is stated that a horse-power of steam costs $39 per year in Rochester, N. Y., $46 in Lockport N. Y., and $45 in Baltimore, Md., making an average of $43.33 per year. At this cost for steam power the difference is $10.47 to cover all other expenses of operating the electric light plants in the nine cities named. The carbons cost $5.40 per lamp per year. This will leave those cities but $5.07 per lamp per year for all other expenses, including depreciation and interest on other investment."

This calculation, so far as it is a mere assertion, may pass for what it is worth in contradiction to statistics compiled by official authority of the Scranton Council. But it is nevertheless a fact that the Brush Electric Light Company, a corporation conducted with a view to large dividends to its stockholders, recently made a bid to do the public lighting of Cincinnati at $52.40 a year for each lamp, and this is less by $1.40 than the average cost in those nine cities. Even though the Brush Company, seeing an opportunity to obtain a larger remuneration, withdrew its bid later, a bond for $50,000 was deposited at the time as an assurance that the offer was originally made in good faith.

---

[1] *N. Y. Independent*, May 15, 1890.

Again it is complained that cities operating their own electric lighting plants, use buildings erected for different purposes, such as gas supply or water works; that their employés put in a portion of their time at other labor; that the superintendent is engaged in the supervision of other departments. It is sought to use these facts to impeach statistics showing the expense of these operations. But the effect is quite the reverse; for this is one of the strongest arguments in favor of municipal management of electric lighting. It shows one of the legitimate advantages which accrue from such control. Electric lighting is but one of those monopolies of service, so closely allied in character and management that their union not only promotes economy but also satisfactory service. Such industries may be conducted much more cheaply upon a large than upon a small scale. This peculiarity of natural monopolies is even being recognized by the private corporations controlling them. Gas companies are everywhere investing in electric lighting plants. It is but an indication of the strong tendency urging monopolies to combine. An instance may be cited. The Cincinnati Electric Lighting Company has just purchased a controlling interest in the five other companies located in that city. This corporation is in turn owned by the Cincinnati Gas Company. All that is still necessary to complete the industrial evolution is that the municipality itself should now step in and unite all under a city management.

It may easily be seen that prices in this industry are not governed by the cost of production. The great difference between the average cost to cities illuminated by contract and to those furnishing their own light gives good ground for this inference. But how strongly is that confirmed by the wide range in which prices charged by private corporations vary! As mentioned before, a bid was made to light the streets of Cincinnati for $52.40 annually per arc light. Peabody, Mass., pays $200 for the same service. Salem, Mass., but a few miles distant, is charged $164.25. Here is a difference of price equal to $147.60, almost 300 per cent. of the lowest offer.

The spread and propagation of these facts are rapidly bringing about the natural result. The number of cities making use of their power to supply themselves with electric light cheaply and economically is increasing with astonishing quickness. So far as known the list of cities which have already operated their own electric lighting plants for a year or more comprises: Aurora, Ill., Bangor, Me., Bay City, Mich., Champaign, Ill., Chicago, Ill., Danvers, Mass., Decatur, Ill., Dunkirk, N. Y., Easton, Pa., Frederick, Md., Grand Ledge, Mich., Hannibal, Mo., Huntington, Ind., Lewiston, Me., Little Rock, Ark., Lyons, Ia., Madison, Ind., Martinsville, Ind., Meadville, Pa., Michigan City, Ind., Painesville, O., Paris, Ill., Portsmouth, O., Topeka, Kan., Xenia, O., Ypsilanti, Mich.

Many more have taken steps in this direction, or are preparing to enter the field. During the year 1889 some twenty municipalities purchased, or took measures for the purchase of, their own electric lighting stations. Within the last few months Peabody, Mass., Sioux City, Ia., and St. Charles, Mo., have voted in favor of municipal plants; a committee of the Council in Oberlin, O., made a report advocating public control; Fort Worth, Texas, voted bonds to the amount of $125,000 for the establishment of a city plant. Chicago is extending its system, while Milwaukee, not to be outdone by her rival sister, has decided to invest $20,000 in apparatus for the manufacture of electricity. A committee of the Select Councils of Philadelphia was so highly pleased that the municipal gas works are not only paying expenses under its new management, but actually earning a profit, that it reported an appropriation of $300,000 for the extension of the public lighting system to the field of electricity. It was only owing to the influence of the electric lighting corporations that this item was stricken off the appropriation bill. This is but one of the many instances in which corporations, claiming to be ever out of politics, have turned their industrial power to use as a political force.

All these facts and figures assist in showing that monopoly is the field for public activity. Monopolistic industries, when given over to the control of private corporations, serve only to oppress and burden the citizen. This is particularly true of street illumination. Municipal management of public electric lighting tends to purify politics, and brings the citizen a cheaper service, better service, more satisfactory service.

THERMO-ELECTRIC INVESTIGATIONS.

Some experiments on thermo-electric currents between amalgamated zinc and zinc sulphate were recently described by Herr K. A. Brander. The primary object of the investigation was to determine the relation between the electromotive force developed and the difference of temperature between the electrodes. The electrodes, of amalgamated zinc were placed in two vessels communicating by means of a syphon, and filled with a solution of zinc sulphate. One of these vessel was kept at the temperature of the place of observation, while the temperature of the other was gradually raised. The *Journal* of the Chemical Society says that the author found that, within the limits of errors of observation, the electromotive force was proportional to the difference of temperature, until this difference exceeded 20.45° C., after which the electromotive force appeared to increase rather more rapidly than the temperature difference. Experiments show that concentration of the zinc sulphate solution increased the electromotive force.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.

Anonymous communications cannot be noticed.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.

In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the serial number of such letter, and of the page on which it appears.

Sketches and drawings for illustrations should be on separate pieces of paper.

All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

THE MARX ACCUMULATOR.

[127.]—In your issue of May 21, an article entitled "The Marx Accumulator" contains the following extraordinary claims:—"If an electric current is passed through a dilute solution of hydrochloric acid and perchloride of iron, in which are immersed carbon electrodes, the following reaction takes place:—$2\,FeCl_2 + 2\,HCl = Fe_2Cl_6 + H_2$. If, then, a carbon and an iron electrode are plunged into the electrolyte, the following reverse reaction, giving rise to a powerful current, takes place:—$Fe_2Cl_6 + H_2O = 1\,FeCl_2 + 2\,HCl + O$. * * * The iron electrodes are not consumed; on the contrary, on open circuit iron is deposited on them, so that they must be removed when the battery is not at work."

The first reaction, $2\,FeCl_2 + 2\,HCl = Fe_2Cl_6 + H_2$, while it is not impossible under the conditions named, is highly improbable. An electric current passing through the solution of a metallic salt tends to reduce, rather than to oxidize, the metal. This is well illustrated in the electro-deposition of nearly every known metal, including iron itself and even such highly electro-positive metals as sodium and potassium. The deposition of iron is accomplished from a ferrous salt. If a ferric salt is used, more energy is required and the ferric salt becomes ferrous as the first stage of reduction.

In the case above cited it is probable that some ferric chloride (Fe_2Cl_6) would tend to form at the positive pole, while ferrous chloride ($FeCl_2$) would be formed at the negative pole. If Mr. Marx can arrange the conditions so that H will be evolved and no O evolved, the reaction may be complete, and he will have a process identical in principle with using an electric current to assist in burning coal!

In the second reaction we have metallic iron immersed in a solution of ferric chloride. It is stated that the iron is not acted upon but the ferric chloride undergoes spontaneous dissociation with liberation of free oxygen and ferrous chloride! And that this dissociation evolves electrical energy!!

The fact is, the reaction, $Fe_2Cl_6 + H_2O = 2\,FeCl_2 + 2\,HCl + O$, cannot take place without a reducing agent which must itself become oxidized, or in some way supply energy. The reaction absorbs energy, instead of evolving it. But the metallic iron used as an electrode *is* acted upon and the following reaction is what actually takes place:

$$Fe + Fe_2Cl_6 = 3\,FeCl_2.$$

If the iron is in the form of a solid mass the action is slow in the cold, but more rapid when heated. If the iron is finely divided, such as iron reduced by hydrogen, the action is very rapid, even when cold. With free HCl present we would also have the following reaction:

$$Fe + 2\,HCl = FeCl_2 + 2\,H.$$

The free hydrogen which escapes in this reaction Mr. Marx has evidently mistaken for oxygen. The black powder of metallic iron and oxides which disintegrates with some graphite while the iron is in excess of the acid was probably thought to be "deposited" iron.

The statement that the iron electrodes are not consumed and that on open circuit iron is deposited upon them is certainly *new* and opens a wide vista. If it is true, we have the remarkable phenomenon of metallic iron precipitating metallic iron from its solutions and remaining itself unacted upon!

Orange, N. J. CHARLES J. REED.

LOWELL, Mass.— A special dispatch from Lowell, of June 1, says: A serious accident occurred Saturday night at the electric light station in Middle street, causing the sudden extinguishing of 300 arc lights in the city. Two employees were working under the shafting, when a rasping, buzzing sound warned them to fly to the next apartment. They had just got there when a heavy counter-shaft, weighing two tons, fell, demolishing the dynamos. The shaft was 23 feet long, 2½ inches in diameter, and upon it hung eight Hunter friction clutches and six belts. The damage is estimated at $2,000.

CORRESPONDENCE.

BOSTON.

Chief Inspector Goddard—A Proposed Electrical Exhibition—Report on Welding, Etc.—Whitney on the West End—A Boom In Thomson-Houston Stock—Close of the Electric Club's Season.

MR. C. M. GODDARD has been appointed as Chief Electric Inspector of the New England Insurance Exchange in place of Captain Brophy, retired.

The subject of holding an electrical exhibition in Boston during the coming autumn has been broached to representatives of several of the large electric manufacturing interests in this city, and appears to have been received with general favor. The exhibition of this nature which was held in Boston some six years ago was a fine affair, and failed only because public interest in electrical matters had not been sufficiently aroused. The case is altogether different to-day. Then electricity in the minds of the general public was more of a curiosity than a thing of the wide utility it has since been demonstrated to be. Now, when people ride in electric cars, and look with favor upon electric lights and motors, and when general interest in the matter is fully aroused, it would seem as if an exhibition, showing some of the latest and most useful novelties of the art, ought to be well patronized.

In the State Senate this week the West End Elevated Railway bill was passed to be engrossed and sent to the House. The Meigs bill has also passed the Senate to be engrossed, and some definite action may soon be looked for.

Lieut. A. B. Wyckoff, of the navy yard, Washington, D. C., who has been making a tour of inspection of several electric plants and factories, has returned to Washington, and expresses himself as well pleased with the results of his visit to Boston. The most instructive result of his trip was a careful examination of the new Thomson electric welding process as seen at their works in West Lynn, Mass. He is convinced that the process is a great success, and that it is but a question of time when the electric welders will come into general use, as doing much more rapid and perfect work than manual labor. Lieut. Wyckoff's tour of inspection was made in connection with the introduction, in the near future, of electric light and power plants at several of the navy yards

President Henry M. Whitney of the West End Railway Company was a guest of the Roxbury Club last Saturday night. His presence evoked a discussion of the rapid transit problem. Mr. Whitney delivered a lucid and exhaustive address upon street transportation. Gen. John L. Swift dealt with the passengers' side of the question, and Hon. Moody Merrill, president of the club, strongly advocated the pending West End bill for an elevated road as the only practical solution of the problem under consideration. Mr. Whitney made a clear and concise and timely statement of the many advantages to accrue from a system of electric rapid transit.

Thomson-Houston stock took a decided "boom" this week and gained five or six points at one time. Various reasons are assigned, new and important contracts, the impending consolidation, and the formation of the new debenture bond company being all fully discussed. Though somewhat premature in publication the *Boston Advertiser* makes the following statement: "The real cause of the sudden demand for Thomson-Houston stock, as exclusively given by me this morning, is the organization of the debenture company, through which it will be possible to realize cash on the securities which the T.-H. Co. takes to a large amount in payment of its work. The wide significance of this matter has not yet fully dawned on the stock market operators Last year the T.-H. Co. did a business of over $8,000,000; the indications are that it will this year do a business of perhaps $15,000,000. Call 25 per cent. of that profit and you have $3,750,000—a sum sufficient to pay dividends on $2,200,000 preferred stock and nearly $20 a share on 180,000 shares of common stock. The trouble hitherto has been that these profits, and more than the profits, have been tied up in the stocks and bonds of local companies. Given a method of realizing upon these local company securities, and the path to cash dividends is easy. This new debenture company will have a capital of $1,000,000, all or most of which will be owned by the Thomson-Houston Co. It will issue 5 per cent. debentures based on collateral bonds deposited with the American Loan and Trust Co. as trustee, $1,250 collateral being deposited for each $1,000 bond issued. The collateral bonds will bear 6 and 7 per cent. interest, and the difference in interest will constitute part of a sinking fund to redeem the 5s. The collateral bonds may likewise be sold, and the proceeds applied similarly. The debentures may be drawn at 102½ and interest. The debentures will be sold through Messrs. Lee, Higginson & Co. and Kidder, Peabody & Co., and the association of these houses with the scheme is a guarantee of success."

A careful perusal of the above statement will give some idea of the enormous growth of the electrical business,—a growth almost more rapid than it is possible to provide for in ordinary financiering. Capital in many cases of local companies, has got to be provided, and though electric light and railway stocks are well taken up, after a local company has fairly started, it is at the same time a little hard for parent companies to carry them till such a time as the stocks and bonds can be floated. The formation of the Debenture Bond Co. will largely relieve this pressure, and though, as I said, the announcement is a little premature, yet it is a fact that a company has been formed for such a purpose, on the lines indicated above.

It is also rumored that a very strong syndicate of English and American capitalists are at present investigating all the electric railways in the country, with a view to the purchase of their bonds, and their ultimate control.

The series of meetings of the Boston Electric Club, are now at an end, and there will be no more dinners or papers read until next fall. The anniversary of the club takes place on June 21st, and it is probable that an excursion to some neighboring beach may be arranged.

BOSTON, May 31, 1890.

PHILADELPHIA.

The Powelton Electric Company's Ordinance—A Denial From J. F. McLaughlin—The Telephone Agitation - Electric Railroading.

THE Powelton Electric Company's ordinance, which was objectionable to the Department of Public Works in the shape in which it passed Councils a week ago, was recalled from the Mayor's hands yesterday by City Councils and amended so as to meet the objections made against it. The bill was then passed by both Select and Common Council. In its present shape the bill provides that "nothing contained herein shall be construed to grant permission to run cars or vehicles by overhead service on any streets of the city. The city shall have the right to use the poles and conduits of said Powelton Electric Company, to attach wires thereto for municipal purposes, without cost, and all poles and wires shall be erected under the supervision and approval of the Department of Public Safety." The clause in the old bill which repealed all ordinances inconsistent with the grant to the Powelton Company was stricken out, and it is understood that the Mayor will now sign the bill. The Powelton Electric Company is chartered for the purpose of supplying light, heat and power by means of electricity to the people of West Philadelphia. For this purpose it is authorized to lay underground conduits and erect poles on any of the streets in that section of the city. The promoters of the scheme say it has not yet been decided whether to build their line underground or overhead. In the outskirts of the city the latter system will undoubtedly be used, but the company is considering whether to adopt this plan for Walnut, Chestnut, Market and other important streets. After the company is once secure in its privilege, and the great difference in the cost of the two systems is laid before its directors it will not take them long to decide which system to adopt, since there is nothing in the ordinance to prevent wires being strung along any street in West Philadelphia. City Councils have for years been struggling with the problem how to get rid of overhead wires. No new overhead lines have been constructed in several years, and the companies have all been notified that within the near future all wires must be buried. Yet in the face of this the Powelton Electric Company has been granted the privilege of erecting an overhead electric light line, and all ordinances which might interfere with this grant are repealed so far as they relate to the Powelton Company. The prohibition against overhead wires is permitted to remain so far as it relates to other companies, so that the Powelton is afforded complete protection from competition. The incorporators are :—John P. Lutz, William J. Latta, William J. Moore, Charles M. Corbin, W. W. Ingram, Samuel A. Welsh, L. A. Lee and Elliott C. Smith. Each man owns 100 shares of stock of the par value of $10, and 10 per cent. of the capital has been paid to William J. Moore, Treasurer.

The American Financial Association, to which the letter here quoted refers, suspended payment some days ago :—

ROOM 281 BULLITT BUILDING,
PHILADELPHIA, May 19, '90.

To the Editor of The Inquirer: My attention has been called to a statement in your issue of this day to the effect that they (referring to the American Financial Association) held possession of the McLaughlin Electric Company, etc.

I beg to correct you in this matter, and state that beyond the fact that Messrs. Macfarlane and Pfeiffer subscribed to and paid for a certain amount of the stock of the McLaughlin Electric Company, and by virtue thereof were elected directors, there is not, nor has there been, any connection whatever between the American Financial Association or any of its stockholders or officers and my company.

I have to add that both Messrs. Macfarlane and Pfeiffer long ago resigned as directors of the McLaughlin Company, and that the vacancies thus created will be filled by the election of gentlemen of undoubted financial standing and ability.

The McLaughlin Company is independent in every way. It has no association or affiliation with any other company in existence. *I personally control it in every way.* Very truly yours,

JAMES F. MCLAUGHLIN.

The chief result of the recent telephone agitation led by the grocers was the allowance of a rebate by the telephone company for time when their instruments were wholly useless. It was stated that the amount of rebate allowed up to date was nearly $10,000. No complaints have been made recently, and the company is making every effort to give good service, and is meeting with much success.

The East Reading, Pa., Electric Railway was opened for business last Sunday, and large crowds used the cars all day.

Experimental trips of the new electric cars on Market street, Camden, N. J., were made on the eastern section of the track a few days ago. It is understood that everything worked satisfactorily.

PHILADELPHIA, May 30, 1890.

ST. LOUIS.

The Municipal Electric Lighting and Power Company.—Important Work on the Lindell Electric Railway.—Electric Railway Work.—Emerson McMillan's Schemes.—Miscellaneous.

The Municipal Electric Lighting and Power Company have increased their capital stock from $750,000 to $1,500,000, the result of which has been the purchase of the St. Louis Illuminating Company. This places the Municipal Company in absolute control of all the arc lighting in the city and also the incandescent commercial lighting by the Heisler system, supplied by the original station of the old St. Louis Illuminating Company.

The only competitors of the Municipal Company are the Missouri Electric Light and Power Company—Westinghouse incandescent—and the electric station of the Laclede Gas Co.—Brush and Heisler incandescent systems—and it is likely that one or both of these will finally be absorbed by the Municipal Electric Lighting and Power Company. The Municipal Electric Lighting and Power Company are controlled by a syndicate composed of Seligman & Co., and Ladenburg, Thalman & Co., of New York, and James Campbell and Mortimer F. Taylor, of St. Louis. John O'Day, president of the company, is the representative of Seligman & Co. The company have also increased their bonded indebtedness from $750,000 to $1,500,000. Statutory statements for this purpose, filed in the recorder's office, show, assets, $1,645,000; liabilities, $1,379,000.

The Lindell Railway Co. have begun the erection of their new power station on Compton avenue. The new station will have an aggregate capacity of 3,600 h. p., one-half of which will be ample for the operation of 215 cars, and will be installed this summer. The remainder of the plant will be added as the traffic demands. The boiler room, 100 x 78, will be fitted with 20 Rohan Bro.'s boilers, 72 x 18, with 4 inch tubes, $\frac{1}{2}$ inch shell and $\frac{5}{8}$ inch heads. Coal will be supplied from a track running through the centre of the building, the boilers being arranged in two rows on each side of the track. The floor of the boiler room will lie some 6 feet below the railway track so that the coal can be fed into the furnaces almost by gravity. The engine and dynamo room cover a ground space of 115 x 89 feet, 24 feet in the clear, with trussed roof and turret skylight for ventilation and leading in mains. The walls are of St. Louis pressed brick with stone trimmings; the inside walls will be faced with finished brick. The floor will be granitoid. Two traveling cranes, each of 5 tons capacity, will be provided for moving dynamos or engines. Eight Armington and Sims compound engines, each of 400 h. p. at 100 pounds pressure and 245 revolutions, will be supplied and erected by E. P. Hampson & Co., of New York. The generating plant will consist of 16 new pattern Edison No. 60 compound generators, each of 150,000 watts capacity, belted direct to the engines. All interior wiring of the station will be run clear of the walls and flooring. The overhead plan of wiring will be used. The dynamo leads and the outside mains all land on two switch tables located in the centre of the room, the tables being centrally located between the eight generators.

The trolley wires will be supplied by the Aluminum Brass and Bronze Co., of Bridgeport, Conn. All high grade rubber insulated wires for feeders and mains will be supplied by the New York Insulated Wire Co., of New York, and fibre insulated wire by the Edison Machine Works. The railway company are erecting their poles and doing their own track wiring. The general contract for line material and fixtures and the erecting of the entire outside electrical work is being carried out by J. G. White, of the United Edison Manufacturing Co.

One hundred motor cars are being constructed by J. G. Brill & Co., of Philadelphia. The cars will be fitted out at the car shops, with interior electrical conduit tubing furnished by the Interior Conduit and Insulation Co., of New York.

A fully equipped machine shop for general repairs is being fitted up at the old car stables on Choteau avenue. The entire plant and equipment was planned jointly by J. H. Vail, chief engineer, of the Sprague Electric Railway, and J. A. McClure, superintendent of motive power, Lindell Railway Company.

The Motor Company filed articles of incorporation on the 19th of April, with a capital stock of $10,000, one-half paid up. The incorporators are James Campbell, E. McMillan, J. C. Van Blarcomb, John Scullin and Robert McCulloch. It now transpires that the object of this company is to experiment with Connolly gas engines, one of which will be received about the middle of June. It will be tried on the Benton-Bellefontaine Road, of which Jas. Campbell is president. The Connolly gas engine was tried by the Missouri Railroad Co. several years ago, and at that time proved to be a very unmanageable piece of fireworks. The inventors now claim to have developed a practical machine

Emerson McMillan, president of the Laclede Gas Co., has gone to Europe, ostensibly for his health, but it is generally known that his object is mainly to interest English capitalists in a scheme for controlling gas industries in the United States. The United Gas Improvement Co., of Philadelphia, who control the Laclede Gas Co., of St. Louis, the Kansas City Gas Light Co. and the gas companies of Burlington, Iowa, and Atlanta, Ga., and also the Heisler system of incandescent lighting, have lately sold out to an English syndicate for $10,000,000. Mr. McMillan's trip will probably result in increasing the capitalization of the syndicate to the sum of $50,000,000. One-half of this sum has already been subscribed by the American members of the syndicate.

A bill has been introduced before the Municipal Assembly, authorizing the St. Louis Conduit Company to construct and operate conduits for electrical purposes.

The bill authorizing the lighting by electric lights of all parks except Tower Grove and Lafayette parks has passed both branches of the Municipal Assembly.

The Vandeventer Avenue R. R. Co. have filed bond for $10,000, also an acceptance of their franchise for an electric railway.

The St. Louis Cable and Western Road is advertised to be sold by special commissioner, June 20th. The road embraces 16 miles of narrow gauge steam road extending from Vandeventer avenue to Florisant Village and a cable division in the city proper some three miles in length. The road will probably be purchased by the newly organized Central and Western, who have a franchise for an electric extension from the junction of the steam and cable divisions to Forest Park.

Mr. Charles A. Benton, special agent of the Sprague Electric Railway Co., made a short stay in this city and reports the closing of a contract with the Greenlawn and Glenwood Road at Columbus, Ohio, for an equipment of five cars.

The East St. Louis Electric Railway Co. have elected officers as follows: G. W. Allen, president; H. F. Bader, vice-president; P. J. Doer, treasurer, and A. D. Sexton, secretary.

Lebanon, Mo., by an almost unanimous vote, has accepted a proposition for electric lighting, and work on the $100,000 hotel and bath house at the magnetic well will commence at once.

The Metropolitan Electric Railway Co., of Springfield, Mo., have been incorporated with a capital stock of $500,000. The new Westinghouse Electric Railway Co. have secured the contract for the equipment of this road.

ST. LOUIS, May 31, 1890.

PITTSBURGH.

Patent Litigation—Allegheny County Light Company's Work—Electric Railway Work.

UNITED STATES Commissioner Gamble has been in this city for the past week. Testimony was taken before him in the United States Court in a suit between the Edison Electric Light Company and Westinghouse, Church, Kerr & Co., of New York. The case has been pending in the courts of New Jersey for some time, involving an alleged infringement of a patent used for the distribution of electricity. The testimony taken went to show that the invention had been used in Pittsburgh prior to the time Mr. Edison claims to have invented it.

The first cars for the Oakland and Linden Grove Electric Railway company have arrived in this city and the road will be in operation within a few days.

Among the latest improvements made by the Allegheny County Light Company of this city is a photometer room which is somewhat of an innovation as an accessory to a central station plant. The company has given this experiment a thorough test and finds it a most useful part of its outfit. The company not only tests the vacuum and candle-power of all new lamps, but also returned lamps are examined, and if the carbon is found to be still intact and in pretty good order, the lamp is put into use again. Over one hundred lamps are thus tested each day.

The new switchboard of the company has quite a number of advantages, but it recommends itself especially for its compactness, the facility with which everything can be handled and its systematic arrangement. The board consists of two separate parts, a lower front part which is smaller, and a larger one arranged behind, covering an entire wall. On the lower front portion of the switchboard are the dynamo regulators for eight 3,000 light Westinghouse alternate current dynamos. Behind and above this are the circuit regulators for twenty circuits, capable of carrying two thousand lights each. There are also three three-thousand light machines of the company run from the Allegheny branch of this station through the same switchboard, making space for a total machine capacity of 33,000 16 c. p. lights.

The management of the Second Avenue Electric Railway Co. of this city is about to build a system of electric street car lines which will be the longest in this part of Pennsylvania. It is projected to run the company's West End line from this city direct to Grafton and Mansfield, a distance of ten miles. The West End line is still operated by horse cars, but the change of motive power is to take place this summer. When the latter road is finished, the company will be able to carry its passengers from Homestead direct to Mansfield, a distance of twenty miles.

General Manager Blaxter, of the Allegheny County Light Co., will leave for England in a few days. Mr. Blaxter will visit his boyhood home in Devonshire and naturally looks forward with keen pleasure to the coming trip.

PITTSBURGH, May 31, 1890.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the last meeting of the Council of the Institute, on May 20, the following gentlemen were elected to associate membership:—

Bunce, Theodore D., Jr., battery expert, the Julien Electric Traction Co., 239 E. Twenty-seventh street, New York city.

Brooks, Morgan, secretary and treasurer, St. Paul Gas Light Co., St. Paul, Minn.

Peck, Edward F., general sup't, Citizens Electric Illuminating Co., cor. Navy street and DeKalb avenue, Brooklyn, N. Y.

Jones, F. R., sup't of construction, the Western Engineering Co., Kearney, Neb.

Bradley, Fred W., United Edison Mfg. Co., 65 Fifth avenue, New York.

Bell, Dr. Louis, Editor *Electrical World*, 167 Times Building, New York.

Williams, Arthur S., electrician, American Telephone and Telegraph Co., 18 Cortlandt street, New York city.

Storey, Imle E., electrician and manager, Storey Electric Drill and Power Co., 16 Broad street, New York city.

Watts, H. Franklin, electrical engineer, Altoona, Pa.

Lozie, Robert T. E., Electrical expert, the Edison United Mfg. Co., 65 Fifth avenue, New York.

Sweet, Henry N., chief of Patent Bureau, Thomson Electric Welding Co., 89 State street, Boston, Mass.

Marks, Louis B., graduate student, Cornell University, Ithaca, N. Y.

Total, 12.

THE NEW JERSEY POSTAL TELEGRAPH COMPANY.

New Jersey and New York capitalists have incorporated a new telegraph company for New Jersey, to be known as the New Jersey Postal Telegraph Company. The promoters of the company are principally residents of Orange and Newark, N. J. The corporators are Everett Frazar, Francis R. Upton and Henry P. Winter, of Orange; Philip Lowry, of Newark; Joseph A. McClary, of Rahway, and Edward Alden, of New York. The paid-up capital stock of the company is $50,000, which will be increased as necessity arises. The President of the company is Everett Frazar.

The company will be operated in close connection with the Postal Telegraph Company of New York, favorable arrangements therefor having been concluded with John W. Mackay. The company will thus be in connection with all parts of the United States and Canada, and through the Mackay-Bennett cables with Europe. About 100 miles of lines will be built at once, running through Newark, the Oranges, Elizabeth, Rahway, Plainfield, New Brunswick, Perth Amboy, Keyport, Matawan, Middletown, Red Bank, Long Branch, Asbury Park, Ocean Grove, and later on every town in New Jersey. Newark is already wired, an existing system there having been purchased. The general manager of the business in New Jersey, with offices at Newark, will be Mr. McClary, at present the manager of the Postal Telegraph Company's Wall street office. The office of the President of the company will be at No. 124 Water street, New York city. The Treasurer and Secretary of the company will be Mr. Alden. It is the intention of the company to give the people of New Jersey a far better service than they now have—a quick and trustworthy day and night service—with special advantages for news matter. There will be no cutting of rates against the Western Union, the chief advantages to be offered by the new company being the superior service which will be guaranteed. It is because the Postal Telegraph Company of New York has not cut rates that it remains the only competitor of the Western Union Telegraph Company. The New Jersey Company has acquired the right to the use of a new patent printing telegraph instrument, and all its despatches will be printed.

MR. G. C. SIMS, of the Armington & Sims Engine Co., Providence, R. I., has been chosen by the Governor of Rhode Island, as one of the State World's Fair Commissioners. The selection is not less admirable than it is popular.

REPORTS OF COMPANIES.

THOMSON-HOUSTON COMPANY.

The Thomson-Houston Company shows this summary of gross sales and profits, also the orders for electric motors and generators for the three months to April 30, 1890, compared with 1889, it being the first quarter of the fiscal year:

	1890.	1889.	Increase.
Gross sales	$2,133,099	$1,139,833	$993,266
Profits	$650,724	$299,613	$351,111
Motors ordered	1,106	247	859
Generators ordered	112	16	96

AMERICAN BELL TELEPHONE COMPANY.

The American Bell Telephone Company reports a net increase in instruments of 469 for the month ended May 20, and an increase of 1,124 for five months. The comparative figures follow:

Month May 20.	1890.	1889.	Inc.
Gross output	6,938	5,902	1,036
Returned	2,135	1,568	567
Net output	4,803	4,334	469
Since December 20.	1089-90.	1888-9.	
Gross output	25,819	23,705	2,114
Returned	10,177	9,187	990
Net output	15,642	14,518	1,124

The total number of instruments in use May 20 was 460,503.

SUB-COMPANIES OF THE ERIE TELEPHONE SYSTEM.

The Cleveland Telephone Company, the Northwestern Telephone Exchange Company and the Southwestern Telegraph & Telephone Company report for the year ending March 31, 1890:

Gross income	$721,860.47
Gross expenses, including dividends paid	719,258.98
Surplus	$2,601.49

SUBSCRIBERS.

Number connected March 31, 1889	11,315
Added during the year	930
Total number connected March 31, 1890	12,245
Proportion of earnings and dividends received by the Erie Telegraph & Telephone Company	$225,061.73
Dividends paid (four) of $48,000 each	192,000.00
Surplus	$33,061.73

The statement of assets and liabilities March 31, 1890, shows:

ASSETS.

Licenses	$2,300,000.00	
Stocks	2,500,000.00	
Unissued treasury stock	200,000.00	
Cash deposits for unpaid dividends	1,471.00	
Accounts receivable	1,351.37	
Cash in banks and loaned at interest	67,660.65	
		$5,070,483.02

LIABILITIES.

Capital stock (par value $100)	$5,000,000.00	
Unpaid dividends	1,471.00	
Surplus	69,012.02	
		$5,070,483.02

COLLEGE NOTES.

Harvard University.

Fleming's *Alternate Current Transformer* has been used as text book in Physics IV. (Electrodynamics) during the last half year. Dr. Fleming's systematic treatment of his subject is very pleasant to the students after their attempts to follow the intricate reasonings of Maxwell. The summaries in the first few chapters are especially helpful in showing the connection between different parts of the subject.

Prof. B. O. Pierce has recovered from his illness, and resumed his classes in Mathematics and Physics at the close of the April recess. Every one is glad to have him back again.

In the course of some delicate experiments, some time ago, it was found impossible to keep the instruments perfectly steady. The independent brick piers on which they were placed were shaken enough by railroad trains half a mile away, and by the men exercising on the ball grounds near by, to disturb seriously the very delicate apparatus, so that it was possible to work only a few hours at midnight, when everything was still. This trouble was finally remedied by placing on the pier a large flat stone, weighing about half a ton, separated from the pier by thick pieces of rubber. The rubber took up the vibrations perfectly, and the experiment was made, indifferent alike to railroads and to base ball players.

At the annual election of officers of the Electric Club, held May 21st, the following were the successful ones, those marked (*) being reëlected. *President*, G. H. Chittenden, '91. *First Vice-President*, *E. H. Lewis, L. S. S. *Second Vice-President*, A. N.

Barron, '91. *Secretary*, H. C. Smith, '93. *Treasurer*, *A. N. Barron, '91. *Librarian*, *G. T. Page, '92. *Members at large of the Executive Committee*, W. R. Westcott, '92; *G. S. Curtis, '92; P. W. Davis, '93.

At the previous meeting of the club Mr. A. N. Barron, '91, read an interesting paper on Storage Batteries.

LEGAL NOTES.

BREACH OF CONTRACT, ETC.—W. K. FREEMAN *vs.* U. S. ELECTRIC LIGHTING CO.

Walter K. Freeman's suit in the New York Supreme Court against the United States Electric Light Company for $100,000 damages for alleged breach of contract and balance of salary came on for trial last week before Judge Ingraham, who dismissed the complaint, holding that the alleged contract with Charles R. Flint, the president of the company, was not binding, as it was not shown that he had authority to make it.

THE RIGHT TO OPERATE A ROAD ELECTRICALLY.

TAGGART VS. NEWPORT, R. I., STREET RAILWAY CO.

This was the suit to enjoin the defendant from operating its road electrically. The Supreme Court of Rhode Island in denying the injunction say:

"The street railway here complained of is operated neither by steam nor horse-power, but by electricity. It does not appear, however, that it occupies the streets or highways any more exclusively than if it were operated by horse-power. The answer avers that 'electricity, besides being as safe and as easily managed as horse-power for the propulsion of street cars, is more quiet, more cleanly, and more convenient than horses, both for residents on the streets used by said cars, and for the public generally, and also causes much less wear and injury to the streets and highways than is occasioned by street cars of which horses are the motive power.' These averments, the case being heard on bill and answer, must be taken as true. We see no reason to doubt their truth. It is urged that electricity is a very dangerous force, and that the court will take judicial notice of its dangerousness. The court will take judicial notice that electricity, developed to some high degree of intensity, is exceedingly dangerous, and even fatally so, to men or animals, when it is brought in contact with them; but the court has no judicial knowledge that, as used by the defendant company, it is dangerous. The answer denies that it is dangerous to either life or property. It is also urged that the cars, moving apparently without the application of external force, alarm and frighten horses. This so far as it is alleged in the bill, is denied in the answer. We see no reason to suppose that this form of danger is so great that on account of it the railway should be regarded as an additional servitude. The answer alleges that a great many street railways operated by electricity, in the same manner as the railway of the defendant is operated, are in use in various towns and cities in different states, and that many others are in process of construction. Reference has been made to cases which hold that telegraph or telephone poles and wires erected on streets or highways constitute an additional servitude, entitling the owners of the fee to additional compensation; and from these cases it is urged that the railway here complained of is an additional servitude, by reason of the poles and wires which communicate its motive powers. There are cases which hold as stated, and there are cases which hold otherwise. But, assuming that telegraph and telephone poles and wires do create a new servitude, we do not think it follows that the poles and wires erected and used for the service of said street railway likewise create a new servitude. Telegraph and telephone poles and wires are not used to facilitate the use of the streets where they are erected for travel and transportation, or, if so, very indirectly so; whereas the poles and wires here in question are directly ancillary to the uses of the streets, as such, in that they communicate the power by which the street cars are propelled. It has been held, for reasons which we consider irrefragable, that a telegraph erected by a railroad company, within its location, for the purposes of its railroad, to increase the safety and efficiency thereof, does not constitute an additional servitude, but is only a legitimate development of the easement originally acquired. *Telegraph Co.* v. *Rich*, 19 Kan., 517. Our conclusion is that the complainants are not entitled to the relief prayed for on the ground alleged; and that the bill be dismissed with costs."

Metal Working:—*Sliding Clamps for Electric Welding Apparatus*, H. Lemp, 428,616. *Electrical Apparatus for Welding Rings*, H. Lemp, 428,617. *Method of Welding Rings by Electricity*, H. Lemp, 428,619.

Miscellaneous:—*Double-Pole Switch*, G. H. Alton, 428,586. *Transformer for Heavy Currents*, H. Lemp, 428,618. *Casing for Induction Coils*, E. Thomson, 428,648. *Electric Switch*, E. Thomson, 428,704. *Register for Gas-Meters*, L. Ehrlich, 428,900. *Electric Switch*, J. F. McLaughlin, 428,935. *Watch Demagnetizer*, F. F. Ide, 429,033.

Railways and Appliances:—*Guard-Wire Protector and Lightning Arrester for Electric Railways*, E. Thomson, 428,658. *Electric Locomotive*, E. Dummer, 428,669. *Device for Maintaining Electrical Connection Between Separate Railway Trains*, D. M. Fike and J. Huffman, 428,748. *Electrically Propelled Vehicle*, A. A. Ingraham, 428,917. *Suspension for Trolley Wires*, E. P. Morris, 428 930. *Device for Suspending Electric Conductors*, H. I. Pierce, 429,058. *Staff Apparatus for Controlling Traffic on Single-Line Railways*, F. W. Webb and A. M. Thompson, 429,074. *Electric Railway*, R. M. Hunter, 429,093.

Secondary Batteries:—*Process of Assembling Secondary Battery Electrodes*, J. F. McLaughlin, 429,049.

Telephones and Apparatus:—*Machine for the Manufacture of Wax-Coated Tablets for Graphophones*, G. S. Taintor, 428,646. *Single-Cord Multiple Switch-Board System*, C. E. Scribner, 428,698. *Coin-Actuated Attachment for Phonographs*, L. Glass and W. S. Arnold, 428,750 and 428,751. *Attachment for Telephone Desks*, B. Schram, 428,818. *Coin-Released Telephone Lock*, H. L. Cassard. *Process of Resurfacing Phonogram Blanks*, O. P. Austin, 429,079.

D. VAN NOSTRAND COMPANY.

D. Van Nostrand Company, 23 Murray and 27 Warren streets, this city, have issued a notice that in consequence of the appearance (ignoring the right of the English author) of a reprint of "Bottone's Electric Bells and All About Them," they have reduced the price of the English edition from $1.20 to 50 cents.

ROSE POLYTECHNIC INSTITUTE.

THE Rose Polytechnic Institute, an advertisement of which appears in the present issue, is one of three or four schools in the United States which are especially devoted to the education of civil and mechanical engineers. One of the peculiar features of the Institute is the thorough and extensive "shop practice" of the students in mechanical engineering. Not only are machines designed and working drawings made, but actual construction is required and is made possible in extensive workshops, the equipment of which has cost over forty thousand dollars. It also pays no little attention to electrical engineering, and is doing good work in that field.

ORGANIZING AN ASSOCIATION OF PHONOGRAPH COMPANIES.

WHILE it may not be of direct interest to electrical engineers, the recent gathering of the phonograph interests in Chicago is one that cannot be passed by without notice. The convention in question, held last week, was composed of licensees of the North American Phonograph Co., and no fewer than 31 such local companies were represented. The meeting was held in the Auditorium Hotel and lasted through Wednesday and Thursday, evening sessions being also resorted to. Among those present were Jesse H. Lippincott, president of the North American Phonograph Co.; Samuel Insull, representing Mr. Edison and the Edison Phonograph Works; Mr. Charles Cheever; Col. Sampson and no fewer than 60 or 70 of the officers of local companies throughout the country.

While to many it seems a matter of surprise that interests still unfamiliar to the public should organize, there can be no doubt that the business-like proceedings and the largeness of the gathering impressed everyone with the fact that the phonograph industry is destined to take a commanding position. Not a few of the men present had passed through the pioneer work in the introduction of the telephone and the electric light; and all were of the opinion that the phonograph to-day is much further advanced, and is, industrially speaking, in a far more healthy condition than were those great applications at a parallel stage of their career.

It is needless to add that a large number of questions connected with the introduction of the phonograph were discussed, the main idea being the adoption of uniform apparatus and uniform methods throughout the country.

The great and interesting feature of the meeting was the use of the graphophone and the phonograph for reporting the proceedings. This was done by the graphophone on Wednesday and the phonograph on Thursday. As fast as the sentences were uttered by each speaker they were repeated into the machine, and thus not a word was lost. It is claimed that the superior qualities of the phonograph in recording and reproducing were remarkably exemplified in this performance, it being possible to dictate to that instrument in a far lower tone than was possible with the graphophone. The results obtained were so perfect and so striking as to open up an entirely new era and field in verbatum reporting. Even accomplished stenographers often find it impossible to keep up with fast speakers, although they may afterwards be able to write out a straight record; but with the phonograph the "recording angel" soon gets the knack of repeating to the machine the words he hears; and he is the quicker to do this if he has had the peculiar training of the memory that is so much an element in the success of the efficient stenographer. The report on Thursday on the phonograph was taken by between 30 and 40 cylinders, which were, of course, immediately ready to be placed in the hands of typewriters for transcription in the ordinary manner. The method followed for repeating, in "taking down" the discussions, was to have two instruments ready, side by side, and simply to move from one to the other, the filled up cylinder being taken off and replaced while the other was being "charged" on the machine in service. This process was as easy to perform as it is to describe and was carried on throughout the sessions without a hitch.

Before dispersing the convention organized formally and permanently, and elected president, secretary, treasurer, etc. Regular meetings will be held, and the membership will be restricted to local companies, as in the case of the National Telephone Exchange Association, a body whose rules and methods have been approximated to by the new Association.

It is believed that without delay the work of stenographic or verbatim reporting will undergo a radical change in this country, as one result of the convention, and that the phonograph with its tireless little electric motor will be the means by which all the legal proceedings, public meetings, debates in Congress, etc., will be recorded.

THE COX METHOD OF CONVERTING HEAT INTO ELECTRICITY.

THE following interesting item of news is from the *Hartford Courant*, of May 31: "For fifty years electricians have been trying to discover a method of converting heat directly into electricity. Until recently no results of commercial value have been obtained. Such a method seems now to have been discovered or invented by a young man from Maine, H. B. Cox. If Mr. Cox's claims are just—and capitalists have confidence enough in them to have formed a company with a capital of $1.000,000—the whole system of power and lighting will be revolutionized and steam will be regarded as too expensive for ordinary uses.

"As has been said, a company has been organized and incorporated in Maine, where Mr. Cox was when some Hartford men met him. Since then the business has all been brought to Hartford, and all that has been done since has been done at the factory of the Pratt & Cady Company. The capital stock is $1,000,000, and none of it is now for sale. Francis A. Pratt, of the Pratt & Whitney Company, is the president; R. N. Pratt, of the Pratt & Cady Company, is vice-president, and Ernest Cady, of the same company, is the treasurer. E. Henry Hyde, of Hyde & Joslyn, is a stockholder, one of the directors, and legal adviser of the new company. All the patents asked for by Mr Cox have been allowed, and they will be issued in a few days. Both foreign and domestic patents have been applied for.

"Before the company was formed Mr. Cox had a furnace at home by which he ran many electric lights. This furnace was injured in being transferred to Hartford. and a new one of the same size has not yet been completed. Experiments and private exhibitions have been conducted here on a smaller scale, but in a short time the company intends to show to the world that with the power thus obtained anything that steam or electricity now does may be done. Several members of the company saw what could be done with the furnace of Mr. Cox before any attempt was made to remove it. The one now being built will be an improvement on the old one, and the results from it are expected to be correspondingly better.

"Most of the stock of the company is owned in Hartford. Some of it is held in Boston. The whole affair has been kept secret until the company should be ready to make it public. Even now the officers of the company are unwilling to talk for publication, but gossip about the new invention has been so frequent in Hartford and elsewhere that it seems proper to print a general statement. The officers of the company say they will be ready for public exhibitions in a few weeks."

THE PULLMAN-WESTINGHOUSE RUMORS.

With regard to the rumors that have been current of an alliance between Mr. George Westinghouse, Jr., and Mr. Pullman, a Chicago paper says:

"The visit to Chicago of George Westinghouse, Jr., who is at the Auditorium Hotel, is said to be in connection with a plan which George M. Pullman and he have been considering for some time for the formation of a company for the construction and equipment of electric street railways. Mr. Westinghouse has a new electric motor and Mr. Pullman is said to be building a car adapted to its use. An exhibition of the electric apparatus was given in Pittsburgh not long ago and the interest then manifested by Mr. Pullman led to the plan for the company's formation. A visit to New York by the two persons most interested led to the promised purchase by capitalists of a large quantity of stock in the new concern when it shall have been chartered. It is probable that the articles of incorporation will be taken out in Pennsylvania. It is not thought that a special plant will be built at present for the construction of the cars and motors, although one object of Mr. Westinghouse's visit to Chicago is to consult about the feasibility of building motor works at Pullman. In a conversation on the subject Mr. Pullman said the selection of a site at Pullman would be of benefit to him and that he regarded the proposition favorably. A new air brake for use on electric cars has been invented and arrangements for its manufacture made at the Wilmerding, Pa., works, and as the motors are now making at Pittsburgh it will be seen that the company will be ready to begin operations immediately on the granting of the charter. Mr. Pullman denied the rumor that a plan for the union of all the street car lines in this city is under consideration; also the one to the effect that a new line was to be built."

MARSHALL FIELD'S WESTERN ELECTRIC PLANT.

Amongst the numerous large isolated plants in Chicago, one of the most important is that which is lighting Marshall Field's magnificent wholesale department building, which could no more dispense with its electric light plant than with its elevators, so important a factor is a cool, powerful and non-destructive light in establishments of this kind.

The electric plant comprises 8 Western Electric Company's arc dynamos, 6 being of 30 light capacity each, and two of 25 lights. These machines are running 212 arc lamps throughout the building, and give a beautifully soft and at the same time powerful light. In addition to the arc lighting machines, are 2 Edison incandescent dynamos, each capable of generating a current of 300 amperes, which at present run some 580 20 candle-power incandescent lights. All the dynamos are run by two Buckeye engines, at present giving 143 h. p., each under a pressure of 70 lbs. by means of countershafting to which they are belted, and steam is obtained from 8 tubular boilers, five only of which are employed during the summer months, three furnishing steam for the above engines and the remaining two operating the elevator engines and furnishing the steam necessary for heating the building. The plant is run all day continuously, and with the greatest satisfaction. Each of the two engines operates one-half of the plant, 5 of the dynamos being coupled to each engine, thus rendering extinction of the light by a breakdown impossible. Mr. Naylor is the chief engineer and electrician, and great credit is due him for the very excellent way in which everything about the whole plant, even to its minutest details, is maintained, and to which its thoroughly successful operation is so largely due.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

FITCHBURG STEAM ENGINE COMPANY.

The Fitchburg, Mass., Steam Engine Company, through Mr. W. E. Sheldon, their treasurer, write us as follows:—"We are running full time and have a large number of orders on hand. We are building engines now for the Springfield Milk Association, Springfield, Mass.; two engines for the Falulah Paper Co., Fitchburg; engine, boiler, etc., for Shirley, Mass.; engine for Standard Thermometer Co., Peabody, Mass.; are putting in a large high speed engine for Orange Electric Light Co., Orange, Mass.; are building one 100 h. p. and one 20 h. p. engine for a large paper mill in Delaware; are just about to start a 50 h. p. engine in the Vanderbilt Building, Beekman St., N. Y., for running their electric lights; are also building a pair of cross compounds for the North Adams Gas Light Co.; also 150 h. p. engine, boilers, shafting, etc., for a large brick concern in Missouri; are just starting a 200 h. p. engine, boiler, condenser, etc., for a large paper mill in Birmingham, Conn.; have recently shipped 50 h p. engine to parties in Springfield, Ohio; also 60 h. p. engine to Frontenac Paper Co., Dexter N. Y.; are building 100 h. p. engine for Bourn, Hadley & Co., Templeton, and recently started a complete outfit for a brick company, in Millville, N. J.; also recently shipped engine to Central America, and are sending our engines all over the world."

PROCEEDINGS OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

The proceedings of the National Electric Light Association at its recent conventions held at Niagara Falls and Kansas City, will be published shortly by the association in two handsomely gotten up volumes. A limited number of pages have been reserved for advertising, and those desiring representation will do well to make arrangements at once for space, with the Manufacturers' Advertising Bureau and Press Agency, 111 Liberty street, New York, who, we are informed, have entire charge of this portion of the work.

QUEEN & CO.

Philadelphia has the reputation, with some, of being rather slow and conservative, but it is interesting to notice that Queen & Co., the well-known Philadelphia makers of electrical test instruments, have pushed vigorously beyond their surroundings and are building up a wonderful business in their line. Until within the last two or three years, practically all the measuring apparatus used in this country was imported from abroad, a popular feeling existing that the value of an instrument was enhanced if a foreign name appeared on it. We are glad to say, however, that such is not the case now. Queen & Co., for example, have demonstrated that they can make electrical test instruments at least equal in quality to the best of foreign makes and as reasonable in price. They are finding customers for their standard resistance boxes, portable testing sets, ammeters and voltmeters and their other specialties in all parts of the United States, and have even had inquiries from abroad. They report a recent large sale to the Northwest, comprising Ayrton & Perry instruments, portable testing sets, Cardew voltmeters, tachometers, etc., to the amount of about $1,500. This is a sample of the demand for their apparatus. We are informed that a new and enlarged edition of their catalogue 166 is in the printer's hands now. It will pay all who desire a copy to correspond with them.

ORDERS FOR EUREKA TEMPERED COPPER.

The Eureka Tempered Copper Co., of North East, Pa., having removed into their new brick plant, report an increased and permanent business for the last sixty days. Among their orders for electrical work during this time, they report good orders from the following manufacturers and plants:

St. Paul City Ry. Co., St. Paul, Minn.; Card Electric Motor & Dynamo Co., Cincinnati, Ohio; Sperry Electric Co., Chicago, Ill.; Brush Electric Co., Cleveland, O.; Westinghouse Electric Co., Pittsburgh, Pa.; Brush Electric Light Co., Buffalo, N. Y.; La Roche Electric Works, Philadelphia, Pa.; Quaker City Electric Co., Philadelphia, Pa.; Rhodes Mfg. Co., Philadelphia, Pa.; Jeffrey Mfg. Co., Columbus, Ohio; Electro-Dynamic Co., of Phila., Philadelphia, Pa.; Riker Electric Motor Co., Brooklyn, N. Y.; Tufts College, Boston, Mass.; Belding Motor & Mfg. Co., Chicago, Ill.; Thomson-Houston Electric Co., Lynn, Mass.; C. & C. Electric Motor Co., New York.; Wenstrom Consolidated Dynamo and Motor Co., Baltimore, Md.; Standard Electric Co., of Vermont, Boston, Mass.; Eddy Electric Mfg. Co., Windsor, Ct.; National Electric Mfg. Co., Eau Claire, Wis.

The use of pure copper without alloys, hard enough for electrical work, appears to give satisfaction and solves a problem that has retarded electrical progress for some time. It is well worth investigation by all electricians who desire durability, perfect conductivity, etc., for commutators, brush material, gear pinions or bearings.

THE PORTER BOILER MANUFACTURING COMPANY.

The Porter Boiler Manufacturing Co., is the name of a new corporation which has succeeded to the business of Porter, Jackson & Co., of Chicago. They have opened fine new offices in the Rookery, and are doing lots of business. Their factory is situated at South Chicago, and their large shops there are equipped with the latest and most improved machinery, thus enabling them to furnish the finest boilers at reasonable prices and very promptly. Among the tools which they have purchased from the best makers in the country may be mentioned the 20-foot rolls, whereby they are enabled to make 2-sheet boilers up to that length. They have also a hydraulic riveting plant of the latest patent, and an improved spacing table together with other new and fine machinery. This company manufactures boilers and accessories of all sizes, of the finest workmanship and finish.

THE GREAT WESTERN ELECTRICAL SUPPLY COMPANY.

The Great Western Electrical Supply Co., George Cutter, manager, are rapidly getting settled in their new and handsome quarters at 190–192 Fifth avenue, Chicago. Carpenters and cabinet makers are very busily engaged in building bins and receptacles for the various electrical supplies which will be carried, and constructing office partitions and the like. The whole of the first floor will be used as a store, surpassing in size anything heretofore attempted in the supply line, where all kinds of goods will be handsomely displayed. The offices which are situated on the second floor will be finished in oak and fitted out with every possible convenience for office work on a large scale. Mr. Cutter has secured the services of an able and well-known electrician to take charge of his house-goods department. Some remarkably large orders have already been received during the last few days, which notwithstanding the present somewhat unsettled state of affairs consequent upon change of quarters, have been filled with old-time promptitude and despatch. Mr. Cutter, although very conservative in his remarks, feels that he is warranted in saying that he is now fitting up and filling with goods, a building which will be the largest electrical supply house in America in the very near future.

SOME NEW WESTINGHOUSE PLANTS.

The following are among the recently established central station electric light plants operating the Westinghouse alternating current system: Grafton, W. Va., 500 incandescent lights; Lebanon, Miss., 500 incandescent and 40 arc lights; Emaus Borough, Pa., 25 arcs; Negaunee, Mich., 25 arcs.

Laconia, N. H., has recently shown her enterprise in the organization of an electric light company, which has since awarded the contract to the Westinghouse Electric Company for the furnishing of alternating current apparatus of 1250 lights capacity.

The Salem Electric Light, Heat and Power Company, of Salem, N. J., after having, for nearly three years, been running a very successful incandescent plant has just decided to go into the arc lighting business also, in order to meet the great demand which is made for that method of illumination. The Company has just contracted with the Westinghouse Electric Company for one of its new arc machines.

The Electric Light and Power Company of San Antonio, Tex., has been in operation since 1887, and it was one of the first in this country to adopt the Westinghouse alternating current system. The company has lately been obliged to make some enlargements in the plant and added new Westinghouse apparatus of 850 lights capacity.

The Westinghouse alternating current apparatus for central station plants has been installed in the following places outside of the United States and Canada: London, England, 25,000 lights; Canton, China, 1500; Halifax, Nova Scotia, 1400; Havana, Cuba, 4500; Juis de Fora, Brazil, S. A., 1500; Santa Anna, Salvador, C. A., 500; Sansonate, Salvador, C. A., 500; Shidsnoka, Japan, 1500; Vancouver, B. C., 750.

The Westinghouse alternating current incandescent system has now been established in nearly three hundred central station plants throughout the country with a total capacity of almost six hundred thousand 16 c. p. lamps. Of these stations the following have a capacity exceeding 1000 lamps: Albany, N. Y., 1300; Allegheny, Pa., 13,000; Allentown, Pa., 1500; Amherst, Mass., 1500; Annapolis, Md., 2250; Aspen, Col., 1400; Auburn, Me., 2250; Austin, Tex., 5200; Baltimore, Md., 5000; Batavia, N. Y., 1250: Bath, Me., 1400; Bay City, Mich., 1500; Beaver Dam, Wis., 1300; Binghamton, N. Y., 3000; Birmingham, Ala., 1000; Boston, Mass., 3750; Bristol, Pa., 1000; Buffalo, N. Y., 3250; Butte, Mont., 2250; Carbondale, Pa., 2050; Cedar Rapids, Iowa, 2050; Chattanooga, Tenn., 1960; Clinton, Ill., 1400; Colorado Springs, Col., 3450; Columbus, O., 2600; Conshohocken, Pa., 1300; Connelsville, Pa., 1500; Cornwall, Ont., 1300; Council Bluffs, Ia., 2250: Dansville, N. Y., 1000; Denison, Tex., 1500; Dennison, Ohio, 1000; Denver, Col., 16,800; Des Moines, Ia., 1000: DuBois, Pa., 1000; Duluth, Minn., 2800; Eau Claire, Wis., 1300; Elmira, N. Y., 1500; Englewood, Ill., 2250; Flint, Mich., 1150; Evansville, Ind., 1300; Fort Worth, Tex., 2300; Galveston, Tex., 1300; Greensburg, Pa., 1350; Hagerstown, Md., 1300; Halifax, N. S., 1400; Hamilton, Ont., 2000; Hartford, Ct., 4750; Helena, Mont., 1500; Hoboken, N. J., 1300; Kansas City, Mo., 3000; Kansas City, Kan., 1500; Lincoln, Neb., 1950; Little Rock, Ark., 2250; Louisville, Ky., 3000; Mansfield, O., 1400; Mauch Chunk, Pa., 1500; Media, Pa., 1500; Minneapolis, Minn., 4500; Moline, Ill., 1500; Montgomery, Ala., 1300; Morristown, N. J., 1300; Nashville, Tenn., 5500; Newark, N. J., 2250; New Bedford, Mass., 5800; Newburg, N. Y., 1500; New London, Ct., 1400; New Orleans, La., 6500; New York, N. Y., 53,500; Oakland, Cal., 1300; Ottawa, Ont., 1500; Oxford, O., 1000; Parkersburg, W. Va., 1950; Peekskill, N. Y., 1300; Philadelphia, Pa., 2700; Pine Bluff, Ark., 1300; Pittsfield, Mass., 2650; Pittsburgh, Pa., 26,450; Pittston, Pa., 1200; Plainfield, N. J., 3900; Plattsburg, N. Y., 1500; Port Jervis, N. Y., 1400; Portland, Ore., 6000; Pottsville, Pa., 1500; Providence, R. I., 7500; Pueblo, Col., 2800; Richmond, Va., 6950; Salem, N. J., 1000; Salem, O., 2050; San Francisco, Cal., 1300; Sandusky, O., 1300; Saratoga, N. Y., 1500; Savannah, Ga., 3350; Schenectady, N. Y., 4100; Seattle, Wash., 1500; Sheffield, Ala., 1300; Sing Sing, N. Y., 1300; Sioux City, Ia., 1400; Skaneateles, N. Y., 1500; Springfield, Mass., 4300; Springfield, O., 1950; Stapleton, N. Y., 5300; Sterling, Ill., 1000; Steubenville, O., 2250; St. Joseph, Mo., 3750; St. Louis, Mo., 15,000; St. Paul, Minn., 4100; Tampa, Fla., 1150; Torrington, Ct., 1300; Trenton, N. J., 3900; Troy, N. Y., 1300; Tyrone, Pa., 1700; Washington, Pa., 1250; West Superior, Wis., 1500; Wheeling, W. Va., 1950; Wilmerding, Pa., 1500; Williamsport, Pa., 2250.

NEW THOMSON-HOUSTON ELECTRIC RAILWAYS.

The Thomson-Houston Electric Company has recently finished the equipment of the following roads on which cars are regularly running: Georgetown and Tenalleytown Street Railway, 6 cars and 6 miles; Vancouver, B. C., Electric Railway, 4 cars and 3.50 miles; Utica, N. Y., Belt Line Railway, Utica, N. Y., 25 cars and 20 miles; Milwaukee, Wis., Cable Company, 12 cars and 15 miles; Knoxville, Tenn., Street Railroad, 5 cars and 3.40 miles; North Side Railway, Fort Worth, Texas, 15 cars and 15 miles; Attleboro, North Attleboro and Wrentham Street Railway, 5 cars and 6.50 miles; the Albany Railway, Albany, N. Y., 32 cars and 14 miles. The power station at Albany is one of the finest which has been built for electric railway purposes. It is a substantial brick building, divided by a brick wall into two rooms, one containing the battery of boilers and the other the engines, generators and electrical appliances. The boilers are ten in number, and have a total of 1,250 horse-power. There are six engines of 200 horse-power each. The generators are twelve in number, two being belted direct to each engine, and are capable of producing 80 horse-power each. The boilers, engines and dynamos rest upon brick foundations, which are supported in beds of concrete two feet in thickness, which obviate entirely all tendency to vibration which is usually found in the operation of heavy machinery. The plant throughout in every detail is constructed in the most thorough and substantial manner, and this, not less than the motor cars, has given the utmost satisfaction since the start. The power house was designed by, and built under the direction of, Mr. L. H. McIntire, the engineer of the Thomson-Houston Railway Engineering Department.

The San José and Santa Clara Railway, San José, Cal., just started, is interesting, not only from its excellent construction, but because it is the first railway in California equipped with the Thomson-Houston system. The road consists of nine miles of track, on which the double overhead construction has been used, and will operate six double motor cars.

NEW ENGLAND TRADE NOTES.

The Wright Electrical Engineering Company have commenced work on the outside construction for the North Adams, Mass., Electric Light Company, who are at present changing over from their old station to the new one. There are in all about 68 arc lights, and about 11 miles of street circuit. The Wright Company will do all the electric work in the station. The Wright Company has also prepared plans which have been accepted for the new station at Taunton, Mass., to take the place of the one which was burned down a few weeks ago. Plans have also been prepared and accepted for Clinton, Mass. The Wright Company recently secured the contract for a 100-light isolated plant for the factory of B. S. McDonald, Boston, and will take charge of the whole construction.

DETROIT TRADE NOTES.

Detroit Motor Company.—Under the successful management of Mr. F. A. Blades this company have so outgrown their present quarters as to have found it necessary to buy ground for the erection of a new and larger factory. The demand for the motors seems to be general.

Detroit Electrical Works.—The new factory of this company is now ready to be occupied, and the removal of machinery, tools, etc., will be completed by July 1st, at which time the business will be pushed harder than ever—if possible.

Detroit City Lighting.—Now that the Detroit Electric Light and Power Company have secured the city contract for lighting the streets of Detroit, the towers owned and operated by the Brush Company will be unused. Speculation is rife over the effectiveness of the pole lighting as it will be carried on by the new company, and the knowing ones say that the towers will be in darkness only till the expiration of the new contract. The Brush Company, in the meantime, are making special preparations to fill the increasing demand for house lighting, and Manager J. E. Lockwood is busy with the details of the increased plant he will install.

WESTERN TRADE NOTES.

Anti-Magnetic Shields. The B. & O. R. R. Co. have adopted the anti-magnetic shield, manufactured by Giles Bros. & Co., as a protection for the timepieces of their employees. This action has been rendered necessary by reason of the very extensive use that they are making of electrical apparatus and appliances. They are also installing the Giles time service in all their principal depots, and have appointed Giles Bros. & Co., of Chicago, as chief inspectors, with a competent staff of sub-inspectors.

The Chas. Munson Belting Co. have recently taken some very large orders for their famous "Eagle" and "Dynamo" belting, some of which run into miles. They have greatly enlarged their factory, increasing its facilities one-third, and now take in Nos. 22–36 on South Canal street. The additions comprise four more floors in the adjoining building, which they are now fitting out with the latest and most approved machinery for the manufacture of their belting specialties. They have acquired an immense reputation for the high class of their goods and the general excellence of their manufactures. They have been compelled to take these steps to cope with their rapidly increasing business, and meet the increased demands with promptness and despatch.

Mr. George Kelley, the inventor and manufacturer of the World's Fair Wire Link Belt, has issued a handsome circular with cuts and descriptive matter pointing out the advantages of his new belting. The advantages claimed for this wire link belting are strength, durability, flexibility, economy and perfection. It is formed of spiral wire links, which are made flat from one inch to three inches wide, coupled together with steel rods. These rods work in horizontal sockets running parallel with the rod, making the link a perfect hinge. These links are not round spirals, flattened, nor are they flat oval, but they are spirals wound flat and set to keep their proper shape to receive the rods which couple them together, or, in other words, to have the proper socket for the rod to work in. The wire used in these links ranges from No. 8 to No. 12, giving the desired strength, and the belt is capable of being run perpendicular, horizontal and twisted, quarter, half or three-quarter turn. It is the easiest belt in the world to lengthen, and this is accomplished simply by the removal and insertion of a rod. It is specially adapted for dynamo work for the following reasons: On a long horizontal stretch, the belt is perfectly straight on the bottom, with a graceful curve turning over the top of the pulleys and the belt running comparatively slack, showing no strain on the belt whatever, and it is equally adapted for any other work where a belt is used.

Shay, Stephens & Co. are quite busy filling the demand for their glass insulators and battery jars. These specialties have gained a reputation to be envied amongst the trade, and their employment is increasing largely all the time.

Mr. Geo. P. Nichols, the Western agent of the stationary motor department of the Thomson-Houston Co., is sending out notices of his forthcoming marriage with Miss Mabel Nobles, of Aurora, Ill., event to take place on June 3d. We desire to congratulate them heartily and wish them many long years of happiness.

The Charles Munson Belting Co., through their New York branch, have just sold a large order of their famous belting, comprising 1,200 feet of single and double "Eagle belting," for use in Brazil, S. A. They are extending their business to all parts and its growth is entirely due to the great excellence of the product which they turn out. Another of their recent orders is one to the American Wire Works, Cleveland, O., of 300 feet of 44 inch three-ply "Eagle" belting.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed*, Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

Vol. IX. NEW YORK, JUNE 11, 1890. No. 110

I have, I think, universally found that the man whose mind was by nature or self-education fitted to make good and worthy suggestions was also the man both able and willing to work them out.—Faraday.

ELECTRIC LOCOMOTIVES IN RAILWAY WORK.

THE large and increasing number of electric street railways now in successful operation having definitely settled the question of their practicability, notwithstanding the misgivings expressed by many who are wedded to the older methods of propulsion, the next stage in the development of electric railroading is undergoing an experience similar to that through which its precursor has passed. The operation of the main lines of railway by the same methods, some time since hinted at in a general way, is now receiving active and serious discussion by electrical engineers; and recent essays on the subject, such as the magnificent paper of Mr. O. T. Crosby, read before the American Institute of Electrical Engineers, have placed the subject in strong relief as a problem involving by no means extraordinary conditions, but, on the contrary, requiring only the application of well defined engineering and economic principles. That this is becoming more generally recognized may be gathered from the fact that journals devoted to the steam railway service which have heretofore remained entirely silent on the subject, on the assumption of its utter impracticability, have recently taken it up for comment and criticism. Thus in a recent number of *The Railway Review* we note an article on this subject which is worthy of attention as indicating some of the aspects of the question as seen from the steam railroad man's point of view. While the writer of the article admits the success of electric propulsion on short lines where traffic is heavy, or on suburban lines in the vicinity of large cities, the statement is made that "when the cost of the stationary engines, dynamos, motors and electrical circuits can be reduced to the amount now necessary to furnish the same power with locomotives there will be chance for the electric motor, but not until then." There was a time, when, we believe, this argument would have been a valid one, but numberless instances can be pointed out that prove its fallacy in the present case. We believe that the investor of the present day considers less the first cost of an enterprise than the prospective increased gain on the outlay, from the most economical apparatus. We see this principle applied daily in the investment of thousands of dollars in coal saving devices by steam users, who, by the application of ordinary business principles, recognize that the reduction in the amount of their coal bills far exceeds the interest on their investment to effect that reduction. This very principle has perhaps more than any other effected the transformation of numerous horsecar lines into electrical roads, the companies operating the former having wisely spent sums aggregating many millions in addition to their present investment in order to secure an increased revenue. The reduction of the cost of the electrical equipment to that of the present steam equipment of a railroad is therefore by no means a paramount condition to be fulfilled.

We read further in the article referred to: "It is pretty certain that at present there are no manufacturers who are ready to build and guarantee electric motors large enough to take the places of the locomotives of to-day, and if they ever do build motors of that size and sell them to railways they must be contented with smaller profits than they now make." With the knowledge of the work which is now being accomplished in dynamo and motor construction we do not hesitate to say that an electric locomotive of the size and power described would at once be forthcoming on a demand for it. Indeed, we are convinced that a contract calling for such a machine would elicit a number of bids with ample bonds for the proper execution of the work. We make this statement not only as a result of our past observation, but because we have recently inspected plans of an electric locomotive of the power designated, which will probably be carried into execution at an early day.

The reduction in the cost of the electric locomotive which our contemporary insists must come about before its adoption can become general, is based on the calculation that an electric locomotive, costing at the rate of $20 per horse power, is twice as dear as a steam locomotive of the same power. In the absence of any definite estimates on the subject, it seems futile to enter into a comparison on this head, but it is more than probable that the estimate given above for the electric locomotive can be largely reduced.

But granted even an increase of first cost, the same rule of economy already pointed out holds in this case. Our contemporary also takes up the question of the method of equipment to be adopted, and shows the difficulties which would be encountered in the attempt to apply a separate motor to each car. So far as this method of operation is concerned, we do not recall an instance in which it has been seriously proposed for regular railway traffic. True, Mr. Frank J. Sprague proposes to furnish the elevated railway cars in New York City with individual motor equipments, but this plan is dictated, he considers, by the strength, or rather the weakness, of the elevated structure which does not permit of a concentration of load on the drivers of a locomotive capable of handling 6-car trains as proposed. We are therefore prepared to agree entirely with our contemporary that if electricity is to be used to move railway trains it must be made to conform in many features to present practice, which is the result of many years of experiment and successful application. Electrical engineers yield to no one in their admiration of what has been accomplished by steam railroad engineers, but they have an unshakable conviction that in electricity they have a better motive agent than steam for a very large proportion of railroad work.

SAFETY DEVICES AND CUTOUTS.

The difficulties with which the early workers in the field of electric lighting had to contend, and the innumerable safety devices which were invented to overcome them, would make an interesting volume indeed. There is, in fact, hardly a property of the current which has not, in some way or another, been called into play in the operation of an electric safety device; and individual properties have been varied in numberless ways to effect the desired end. Among these the heating effect of the current is probably the one most generally employed in a cutout and the fusible plug is probably justly considered to be the most reliable and simple device of this nature when properly proportioned. But it has come to be recognized that if the fuse can be assisted in its work by some means that will insure its quick action, additional security will be attained. An ingenious device of this nature is the air space cutout designed by Mr. W. J. Jenks, and described in another column. Relying upon the "jumping" power of the current, Mr. Jenks inserts an air space of corresponding width in the path of the circuit, which, acting in conjunction with the fuse or other device, makes the action of the latter certain.

We are very glad to see the great attention, thus indicated, now being paid to the question of safeguarding circuits that carry small currents against invasion by heavy currents. The matter is one of the highest importance. Indeed, we sometimes think that it is one of the points in which even a little legislation would be beneficial; but probably, before long, the universal opinion among electrical engineers will enforce the rule that no apparatus of whatever class shall be without its appropriate "safety" device. The cost of such insurance will be insignificant in comparison with the immunity secured from danger.

Electric Motor Launches.

One of the features of boating on the Thames, above London, has been the use of electric launches, current for which is furnished from storage batteries. These launches have now been shown also at the Edinburgh Electrical Exhibition, on the adjacent Union Canal, and have excited very favorable comment. It is a little surprising that nothing of the kind has been seriously attempted here, if only on the lakes of the larger parks of such cities as New York and Brooklyn. Perhaps the main difficulty lies in the rarity of charging stations, but there are ways to overcome that. If nothing of any magnitude can be done before 1892, then it is to be hoped that at that time visitors to the World's Fair will find a whole flotilla of electric launches awaiting hire, not only in the parks, but on Lake Michigan itself.

Electric Hoists on Docks.

The application of the electric motor to the loading of vessels alongside docks, though evidently within reach, has up to the present been practically neglected, owing no doubt to the enormous development of, and attention absorbed by, the other branches of motor application. We are therefore pleased to see that a start has been made in the direction mentioned by the installation of an electric hoist on a dock in Brooklyn, in which it is principally employed in the loading of cotton. The highly inflammable character of this material, and the general inhibition against the employment of boilers and steam engines on docks, makes this installation one of note, and sets an example which will be largely followed in the near future. Our progressive friends in the South, especially, would do well to keep this application in mind.

The Permeability of Iron.

The study of the magnetic properties of iron has of late years been taken up with renewed vigor, and as a result some of the theories of magnetism thus far offered to account for the phenomena observed are gradually undergoing modification, while others are becoming untenable in the light of modern research. Any research which can throw some light on the nature of magnetic action is therefore of special value at the present time, and hence the results obtained by Mr. A. E. Kennelly, as embodied in an admirable essay on another page, will be read with interest. In this original research, Mr. Kennelly arrives, at least in one case, at the fact that the permeability of wrought iron at right angles to the direction of magnetization is relatively increased. With the observed phenomena as a basis, Mr. Kennelly discusses the various theories of magnetism now in vogue, and proposes another which is designed to reconcile the discrepancies existing in them as they now stand.

Friction on Dynamo Bearings.

The excellent workmanship which is now being bestowed on the manufacture of dynamos and motors has effected considerable economy in the power absorbed by these machines, but it may not be amiss to call attention to the fact that improvement in some directions is still desirable. Where motors, for instance, are coupled directly to the machine to be driven, the loss in friction at the bearings will, under any condition, be comparatively small, but with the transmission effected by means of belting, the loss in friction at the bearing may, under certain conditions, be comparatively high. This is well shown in the results of experiments in this direction given in another column, in which it is shown that under a light load the existing forms of bearings may absorb quite a large percentage of the total power developed by the machine. Too much stress must not, of course, be laid on conclusions based on a single series of tests with only two bearings compared, but the results reached plainly demonstrate the necessity of lessening, so far as it can be done, the friction of the journal bearings of dynamos and motors.

THE JENKS AIR SPACE CUTOUT.

The evolution of methods for street lighting by incandescent lamps has developed more than one device in which are apparent no little ingenuity and the results of years of experience. The most of these apply either to current regulation of series circuits, where several loops are operated in parallel from one dynamo, or to the preservation of the continuity of any series which may tend to become broken by the rupture of the most delicate and practically the only destructible portions of the circuit, namely the lamp carbons.

As by the normal operation of the system these incandescent bridges burn out one after another, the rise of the potential at the terminals of each dying lamp tends to form an arc across the consuming ends of the carbon loop at the point of rupture, and one of the most difficult problems which has presented itself has been to suppress this arc before its vicious action could destroy the carbon terminals, eat its way through the seal and possibly melt the base of the lamp and the mechanism of the socket into a heterogeneous mass.

The first plan adopted by the Edison Company in the operation of the "municipal system" was to shunt each lamp and its socket by a high resistance magnet. Upon a material increase of potential above that normally expended in the carbon, such as would result from a decided tendency to break the circuit in the lamp while burning, or from a connection with a dynamo of 1,000 volts after the circuit had been accidentally opened in the lamp or its socket, this magnet would attract an armature, which by a locking mechanism was made to securely close a short circuit. The main difficulties with this device arose from the unreliability of any apparatus involving mechanically moving parts exposed to the moisture of the out-door atmosphere and seldom operated, and from the fact that a rupture of the carbon, the most obvious and frequent cause of increased resistance and consequent rise of potential, usually developed an arc of a resistance hardly greater than that of the carbon loop itself, and sometimes actually less.

After a long series of most interesting experiments, Mr. Edison applied to the lamp a principle which he had used very early in the art in connection with a current regulator, and later (in 1883) as a potential indicator. A third wire is sealed into the stem between the leading conductors, its inner terminal extending into the vacuum space a short distance, and its outer end connecting with a fusible wire holding a short-circuiting spring in tension. During normal action this middle wire carries no current, but when an arc occurs between the carbon clamps a portion of the current is taken up by the intermediate channel, and melts the fusible wire, liberating the spring and closing the circuit around the lamp.

The great importance of this continuity of a series circuit has necessitated the addition of a second or reinforcing cutout in the socket, and for this a very effective and cheap device was in 1885 arranged in the form of a "film" or "paper" cutout, an application of the old telegraph lightning arrester, in which a sheet of paper was interposed between a line plate and an earth plate, and when punctured by a disruptive spark, short-circuited the instruments. In order, however, to render the film reliable it was necessary to use paraffined paper or some other moisture-proof equivalent, and to make the operation certain at comparatively low pressures, say 500 volts, it was essential to use a thickness of about $\frac{1}{1000}$ inch. This frail barrier was so often broken through as to become troublesome, and after about three years of practical work an improvement was seen to be indispensable.

This was presented in an arrangement for which a patent has just been granted to Mr. W. J. Jenks. It involves the principle of another old form of lightning arrester, similar to the first, excepting that an air space takes the place of the film of mechanical insulation, so far as to form the path for the disruptive spark. It is a curious fact that the resistance of an air space, though practically immeasurable by any of our most delicate instruments, is overcome by a lower potential than an equal thickness of mica, paper or other mechanical insulator, which is so much better as a conductor as to be readily measured by an ordinary bridge.

Taking advantage of this Mr. Jenks has adopted the ordinary plate lightning arrester to the uses of electric lighting, power, telephone, telegraph, burglar alarm, fire alarm, and other circuits employing, or likely to conduct, either atmospheric or dynamic currents, by enclosing or separating the surfaces by a wall of refractory material, such as mica, or lava, which is also practically moisture and dust proof. This method of enclosing within an isolated cell, the air space which is to be relied upon to form the track of the current, is found by careful experiment to be absolutely essential in dealing with the low potentials from which delicate instruments must be protected, and the very close adjustment required to provide for a short-circuiting action with a predetermined potential may be secured by several methods. For the purposes of the "municipal system" it is sufficient to bring the opposing conducting surfaces within about $\frac{3}{1000}$ inch of each other, while for other uses it may become necessary to narrow the space to about $\frac{1}{2000}$ inch.

Evidently adjustments as delicate as these can in practical work be made by the ordinary operative only by interposing between the electrodes a distance piece or washer of definite thickness, having one or more holes through which the discharge will occur, and this distance piece forms one of the most important points of the invention. It may consist either of mica, of perforated paper, silk bolting cloth or other suitable perforated film. By its means it is easy to set this potential cutout so that a rise of pressure from 150 to 200 volts, or even from 75 to 100 volts, will operate it with certainty, and cause the shunt to carry, either as a dead-short circuit or through a compensating resistance to the line beyond, or to ground, as the case may be, the normal current which might otherwise be broken, or the accidental current from some high pressure circuit, which might injure the instruments, and interfere with the circuits.

The accompanying engraving, Fig. 1, shows the air space cut-out as applied to an Edison "municipal" lamp, and Fig. 2 shows its construction. As will be seen, it consists simply of two plugs, L and L′, which are screwed into the sleeve K, against a washer *n*, of insulating material, which has an aperture; the air space thus formed constitutes a bridge across which the current passes when the potential exceeds a given amount corresponding with the width of the air space.

One of the best evidences of the utility of this device is the fact that several thousand have been in satisfactory use on the Edison "municipal" circuits in this country for about two years.

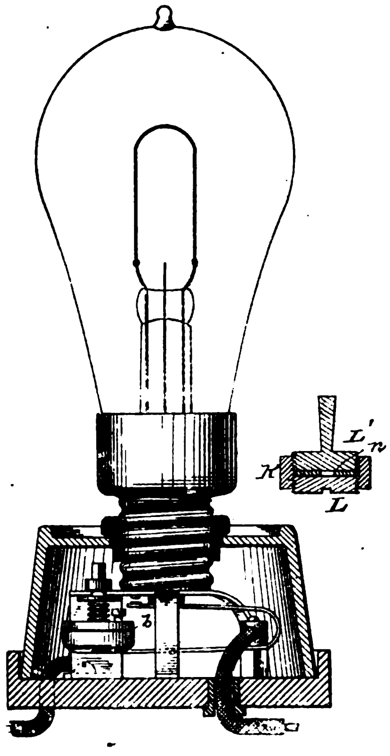
A more important application of the idea was shown at a recent test before the Underwriters of New England, of a large number of devices proposed for adoption as protectors of telephone and other "innocuous" circuits from the effects of accidental contacts with high pressure wires. While many of the forms of apparatus then submitted operated promptly to open a grounded circuit even by the application of abnormal currents of low amperes, the air-space cutout (or some equivalent device) in combination with a fuse, electro-magnetic or other circuit-opening apparatus, was pronounced by the insurance inspectors to be absolutely essential to the safety of the instruments, operators and patrons of metallic circuit systems likely to become crossed with high pressure lines.

The application of the air space cut-out to a grounded circuit is shown in Fig. 3. Here a telephone wire T comes into electrical contact with a point C in an arc circuit. If no leakage to earth has previously existed on the arc circuit, no current will, of course, flow through the telephone line in consequence of this contact. If, however, another path exists, as at G, a difference of potential will be at once set up between the point at the cross C and the point where the telephone line is grounded at E, causing a current to flow through the line T, the fuse, and either the bell B or the telephone, according as one or the other may be in use.

If the air space cut-out at A S be so applied as to form a path or shunt around the instrument with a break of a small fraction of an inch air space, the difference of potential, if amounting to a predetermined standard of, say, 100 volts, to which the plates of the air space cut-out have been adjusted, a disruptive spark will bridge this air space and establish a sufficient connection between the plates to allow of a continuous flow of current through the fuse for a sufficiently long interval of time to melt it and open the circuit. This action will probably take place simultaneously at both ends of the line, or at a point beyond the cross where a similar fuse and cutout have been placed.

Thus the central station, or any intermediate office, would be protected as well and as promptly as that of the customer.

This combination of air space cut-out and fuse produces for metallic as well as for grounded circuits a result more sure, so far as the melting of the fuse is concerned, than can be secured with a fuse alone. The existence of a cross with any high pressure wire, or with any wire whatever capable of producing a predetermined difference of potential of moderate degree, as 50 or 100 volts, between the telephone circuit and the earth, instantly results in a disconnection of the portion of the line within the building from that outside.



Figs. 1 and 2.—The Jenks Air Space Cutout.

With any device operating merely to break the circuit by means of the flow of an abnormal current, and which does not respond to a rise of potential with respect to the earth, no indication or warning would necessarily be received of such a cross until by some means, as by an accidental contact of a person operating the telephone with one of the binding posts of the receiver and a steam, gas or water pipe, the circuit would be completed.

It is evident that the protection of complete metallic telephone and similar circuits can also be effected by similar means.

In applying the device in such cases, it had been found that electrodes of carbon suitably prepared and properly separated by a washer of mica, afford specially satisfactory results, making it easy to adjust for very low potentials, while reliability is not seriously jeopardized by the use of magneto call currents, as on telephone lines. With such a construction an ordinary discharge forms a momentary arc of low resistance across the space, opens the circuit instantly by melting the fusible strip or actuating the electro-magnetic device, and is ready for a second service as soon as the circuit is restored.

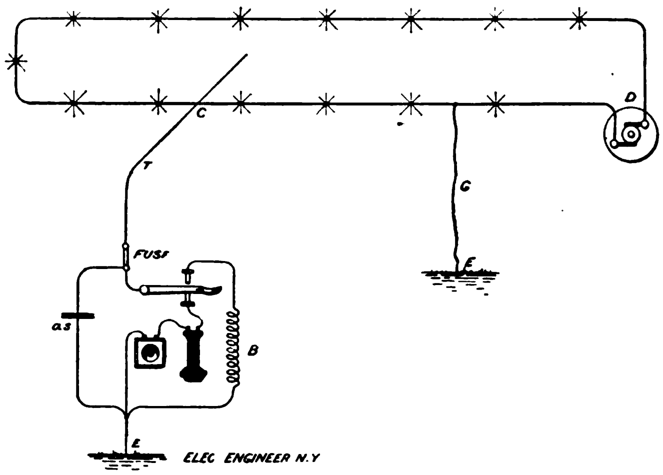


Fig. 3.—The Jenks Air Space Cutout.

It should be remembered that the general adoption of circuits without ground connections for many widespread uses is foreshadowed by the results of years of fire-alarm telegraph work, and by the recent experience of the telephone people in long distance service and comprehensive city switchboards and cables, and that the basis upon which safety (from shocks and fires) in the use of such circuits could be secured was pointed out by Prof. Elihu Thomson in one of the most important papers read before the National Electric Light Association at Kansas City in February last. With these facts in view it will be seen that devices like the one to which allusion has been made are worthy of the most careful consideration by all those personally responsible for the safety of modern electrical conveniences, and also in a very important sense by those who use them with only a general and superficial knowledge of the proper conditions of their operation.

FRANKFORT ELECTRICAL EXHIBITION.

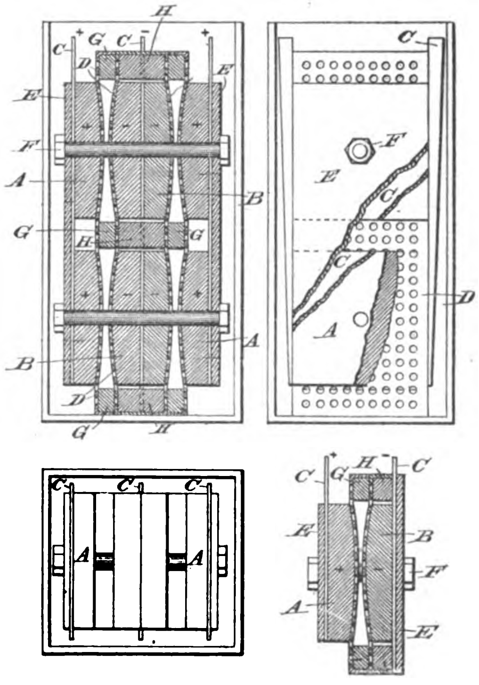
The preparations for the electrical exhibition to be held at Frankfort-on-Main next year are being rapidly pushed forward. Among the numerous applications already received the Swiss Maschinenfabrik "Oerlikon" is noticeable. In connection with electric shipbuilding, the firm of Escher, Wyss and Co., of Zurich, will send a large electric boat, driven by accumulators and capable of carrying 100 persons. This boat, which will be artistically fitted, and furnished, of course, with electric light, will ply on the River Main to serve as aid in the traffic between the interior of the city and the eastern part, where the exhibition is situated. In view of the scope offered for the use of an electric boat service on the lakes in South Germany, Switzerland, and Austria, this part of the proposed exhibition will be regarded with especial interest. We also understand that the Electro-Technical Society of Frankfort have decided to organize an international electrical congress, at the time of the exhibition, at which numerous practical questions will be discussed. At a recent meeting of the organizing committee of the Exhibition it was resolved that, having regard to the expenses and sacrifices which electrical firms and houses taking part in exhibitions of this kind are put to, it is only just that they should be allowed to share in the profits of the undertaking.

HERING'S STORAGE BATTERY.

In a patent recently issued to Mr. Carl Hering, of Philadelphia, the inventor describes a new process of manufacture of the positive and negative plates, which involves several novel features.

For the preparation of the positive plate Mr. Hering employs a dry mixture of powdered peroxide, minium, and lead carbonate (or sulphate) which is mixed with a solution of acetate of lead to a stiff paste. This is then pressed into a mold and punctured in numerous places and dried in an oven. It is then hardened by immersion in sulphuric acid, after which it is mounted and formed.

Secondary battery plates are usually formed in sulphuric acid. Mr. Hering prefers, however, to form them in an alkaline-sulphate solution—such as sodium or or potassium sulphate—as this prevents in a degree the formation of the peculiar white growth around the supports, which attacks the latter when made of lead. After they are formed such growths do not appear. The plates are furthermore strengthened and hardened by a process called "treating." This consists in immersing the plates in a solution of a soluble lead salt or compound—such, for instance, as acetate of lead—then drying them and afterward forming them again with a positive current, as usual. This may be repeated as often as desired, thereby giving the plate any degree of hardness and density. By this process of treatment the soluble salt of lead on drying forms a thin coating on the surfaces of the porous spaces, and on its conversion to peroxide decreases the size of the porous spaces without diminishing their number.



Hering's Storage Battery.

To still further strengthen the plates and render their surface very hard, Mr. Hering electroplates them, after they are formed, with peroxide of lead, by supporting them in a bath of a soluble lead salt—such as the nitrate—together with a suitable cathode, and passing a current through this, making the plates the anode. They then become coated with a layer of deposited peroxide of lead, which is about as hard as highly-tempered steel.

For preparing the negative plates of his battery, Mr. Hering passes a heavy current through an acid bath made of a soluble salt of lead—such, for instance, as the nitrate. The anode in this bath is a slab of lead, and the cathode, straps or wires of lead terminating in points. Arborescent crystals of lead will then be formed at the cathode in large quantities. These crystals are exceedingly thin and possess the property, when fresh, of adhering to each other, or interlocking when pressed together, thus forming a very porous, tenacious mass which is soft, pliable and fibrous, almost resembling a textile material. These crystals are gathered and kept under water until a sufficient quantity is obtained for a plate. They are then put into a mold and sufficient pressure applied to make them adhere to each other. By this means a porous, strongly coherent plate of finely divided lead is obtained which is said to be admirably adapted for the negatives of secondary batteries. The plates prepared in the manner described above are assembled in special manner which is illustrated in the accompanying engravings, the object being to support them so that they can be readily removed and inspected without having to unsolder joints. As will be seen, the blocks of peroxide, A A, are made flat on one side and somewhat cylindrical on the other; B B being the negative plates. The replaceable conductors C C lie against the flat sides of the positive blocks, while the perforated insulating strips D D lie against the rounded sides. The insulating bolts F F which pass through the whole set of plates serve to bind them firmly together, the rubber stops, H H, serving to relieve the negative plates from the excessive pressure due to the bolts F F.

By this construction, the only perishable part, namely, the lead conductors for the peroxide plates, can readily be replaced at small cost, and any defective blocks can readily be renewed, and a block which may break will not necessarily fall out, but will remain in as good working condition as before. The dead-weight is also reduced to a minimum. Ample room is given for expansion in all directions, as well as for unequal expansion of the active material and its conductor, and buckling is thus claimed to be effectually prevented.

A NEW ELECTRIC COAL CUTTER.

The Thomson-Houston Motor Company of Boston, has put in operation an electric coal cutting machine which has attracted attention from mining men throughout the country. The machine is in practical operation near Osceola, Pa. The plant consists of a 7 h. p. steam engine belted direct to a 7 h p. generator. The electric current is conveyed through the mine to the coal cutter, by a wire suspended along the roofs of the chambers. The cutter in this case is nearly a mile from the generating plant. A 5 h. p. motor operates it, and is compactly placed on the same bed plate with the machine. The cutter itself consists of an iron frame 24 inches high, 8 feet 6 inches long, and 36 inches wide. Nine auger shaped drills similar to those now used in mining are placed in the lower part of the frame. Between each drill is a steel cutter-bar which cuts all coal left between the holes drilled by the auger bits. On the under side of each cutter-bar are attached several scrapers which hang loosely and pull all the coal back as fast as it is cut or drilled, keeping it out of the way and making the opening clear. All coal taken out of this cut is coarse and none is wasted.

The height of the cut is four inches. The machine makes two cuts in five minutes, as it is easily handled and needs only to be pushed along the breast by lever bars. The switches and controlling devices are so placed that one man easily operates the cutter. The machine is provided with twin wire cable which is long enough to extend along any ordinary chamber, and does away with the need of permanent wiring except in the headings. A suitable truck is provided for the cutter, upon which it may be carried around the mine with ease. An ingenious device will be provided on future machines, by means of which the motor will pull itself and the cutter off and on the truck as required. The weight of the complete machine is a little over one-half a ton. One strong point in favor of this machine is the readiness with which it accommodates itself to varying hardness of strata. The motors are wound for but 220 volts pressure, so that all danger from high potential currents is done away with. The capacity of the machine is 180 tons of coal per day of ten hours in a four foot vein. Several improvements on the first machine will be embodied in the regular apparatus which is now being manufactured at the Thomson-Houston Motor Company's factories, Lynn, Mass.

ON THE REDUCTION OF THE FRICTION ON THE JOURNAL BEARINGS OF DYNAMOS AND MOTORS.

THAT the loss in efficiency of dynamos and motors, due to the friction on the journal bearings, is considerable, is well understood. But the magnitude of this loss when the machines are under light loads has not been fully appreciated, or if so, has not been given the prominence which it deserves.

On machines under full load the friction on the bearings may be said, in general, to be a very small and often negligible proportion of the total resistance; when, however, the load grows less, this bearing friction becomes a much larger proportion of the total resistance and introduces a loss in efficiency which cannot be considered negligible. This is particularly the case with machines which, while running all the time, are only occasionally under load, as is the case with elevator motors.

In the following are described certain tests made in the laboratory of the Massachusetts Electrical Engineering Co., on an anti-friction roll journal bearing designed especially for dynamo and motor use, and the results of which tests show the importance of the subject.

Efficiency tests were made upon a Weston 15-light arc dynamo, running as a motor, with first, the regular phosphor bronze bearing; second, the anti-friction roll journal bearing.

The armature shaft was of steel. In all, twenty-four tests were made, the object being to make a complete test with each bearing under similar loads. This was accomplished by the arrangement of apparatus shown in Figs. 1 and 2. The motor was belted to a pulley, driving the shaft through an Emerson power scale. On the same shaft was a friction brake, regulated by a tightening screw, and cooled by a tank of water. Great care was taken to keep the belt tension the same; its constancy was assured by weighing, before and after each test, the downward pull of the centre of the belt when raised to a certain height by a special contrivance for the purpose.

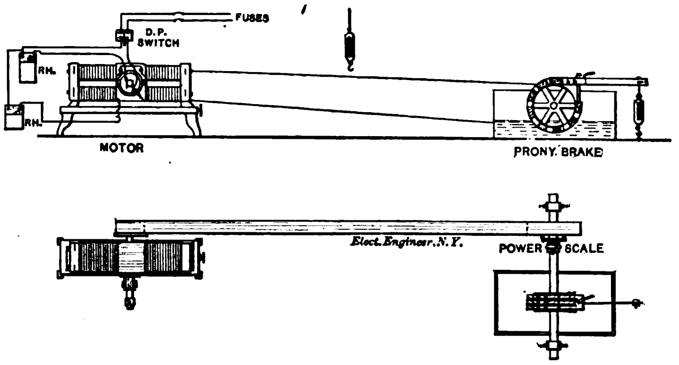


FIG. 1.—MEASURING FRICTION ON DYNAMO BEARINGS.

The electrical measurements were made with a Weston voltmeter and ammeter. Simultaneous readings were taken of the current, electromotive force and speed at the motor, and the weight on the power scale and speed at the countershaft. The Prony brake was used as a check for the power scale.

The commercial efficiency was calculated for each test and a curve drawn for each series, one with the phosphor bronze bearing and the other with the anti-friction bearing. The curves were drawn with the horse-power delivered at the countershaft as abscissæ and the efficiencies as ordinates. From these two curves the increased efficiency at any horse-power output could be found. Fig. 3 is a curve representing the percentage of increased efficiency with the anti-friction bearing.

With the motor running free, 7.9 per cent. more power was consumed with the phosphor bronze bearing than with the anti-friction bearing. With a load of ¼ h. p., the percentage increase in commercial efficiency was 59 per cent. With a load of ½ h. p., the percentage increase in commercial efficiency was 37 per cent. With a load of 5 h. p., the percentage increase in commercial efficiency was 13.5 per cent.

With a load of 7 h. p., the percentage increase in commercial efficiency was 13.3 per cent. With a load of 12 h. p., the percentage increase in commercial efficiency was 4.8 per cent.

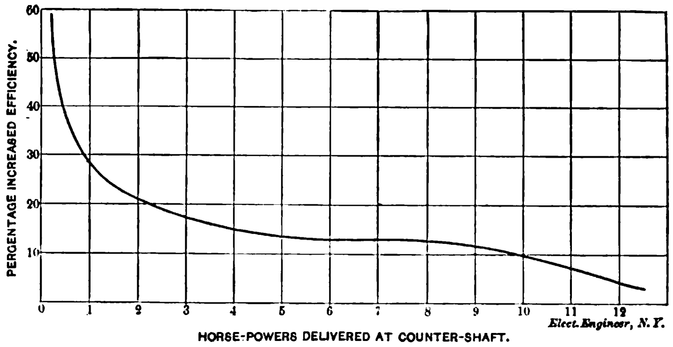

FIG. 2.—CURVE SHOWING INCREASE OF EFFICIENCY WITH INCREASING LOAD.

The greatly increased efficiency on ¼ h. p. load was due to the fact that the journal friction due to the belt tension constituted nearly the whole load. During the test the phosphor bronze bearings were kept as cool as possible. The roll bearings were lubricated when put on to the motor and were not again touched during the test; they did not heat at all.

The results of these tests fully substantiate the assumption that when not under full load the bearing friction is an important factor of the loss. This is all the more important as it has been the practice of nearly all the power companies to install motors of a capacity much above the work required from them, in order that overloading should not occur. In printing office work, for example, the motors are often under half load for the greater part of the time.

ELECTRIC LAUNCHES AT THE EDINBURGH EXHIBITION.

PROPULSION by electricity is effectually demonstrated at the Edinburgh exhibition. The site favored this, as it is skirted by the Union canal, and four launches are running on the canal. These were designed by Messrs. Morton & Williamson, Glasgow, and built by Messrs. T. B. Seath & Co., Rutherglen. The dimensions are 40 feet long, 6 feet 6 inches beam, and the draught of water is 2 feet 1 inch. They each carry forty passengers. The electrical equipment has been supplied by Messrs. M. Immisch & Co., London, and is similar to that used on the Thames launches. The charging plant consists of a 25 horse-power engine and an Immisch dynamo, and the switch arrangement is suitable for charging all the four launches at the same time. The recharging is done during the night and the launch can run ten to twelve hours. The motors are capable of an output of about 3½ brake horse-power, working up to 800 revolutions per minute, and the speed with the maximum load on board is six miles an hour. The propellers are coupled direct to the motor shaft. A ball-bearing thrust block is attached to the motor's bed, and is constructed in combination with the plain bearing of the motor. This is the invention of the Messrs. Immisch, and has been patented by them.

ON THE PERMEABILITY OF IRON AT RIGHT ANGLES TO THE DIRECTION OF MAGNETISATION.—I.

BY A. E. KENNELLY.

Weber's theory of magnetization in the modified form suggested by Clerk-Maxwell is that which appears to meet with the most general acceptance, and it is a notable feature of this theory that it considers the restituting forces acting on the molecule to be a function only of their displacement angle, and to be independent of any mutual reactions between the molecules themselves during magnetisation, or of the influence which combination in polarity might exert upon the equilibrium of their intermolecular forces.

The intimate relations which have been found by so many observers to exist between the mechanical and magnetic conditions of iron in the mass, such for instance, as its alteration in dimensions by magnetisation, the change of its magnetic properties under mechanical stress, the sounds emitted by iron bars under electromagnetic impulses, and the variations in the permeability of iron under varying temperatures,—all suggest the *a priori* probability that the orientation of the molecules supposed to take place during magnetisation, would call into play molecular reactionary forces of a mechanical or magnetic nature, whose effect upon the process would not be negligible, especially in advanced stages. It might be expected, in fact, that these molecular reactions would impede the progress of magnetisation to an extent increasing as that process was continued towards the maximum limit.

Among the wide variations in magnetic behavior exhibited by different specimens of iron differing sensibly in constitution, and the consequent latitude that a theory including all of them must possess, it would be difficult to detect the influence of any such reactions by direct calculation or comparison; but their effect would probably be to increase the apparent relative permeability of iron at right angles to the direction of magnetisation. That is to say, feeble magnetic forces brought to bear upon strongly magnetised iron would probably produce a greater magnetic displacement at right angles to the existing magnetisation than when coincident with it in direction, owing to the expected absence of reactionary forces in the former line.

TABLE I.

The experiments about to be described, were made with the object of detecting any such difference of permeability if it existed. The results may be considered to have rendered a difference distinctly discernible, in the case of one sample of wrought iron, but with the specimens of cast iron and steel also tested, the conclusions are doubtful; for, although the values obtained for their permeability are certainly greater than theory would warrant, they are not much more divergent than those obtained by the same method for their permeability in the direction of magnetisation itself.

While the success of the investigation has thus been only partial, the interest which attaches to the subject will, perhaps, be sufficient excuse for its complete presentation in condensed and tabular form.

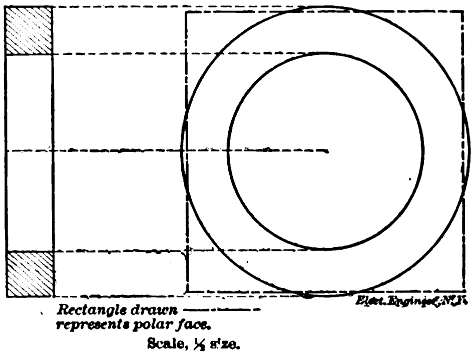
The first experiments were made with a hollow cube of cast iron, 6 cms. in length of edge. Two opposite sides of this box were wound with narrow coils of insulated copper wire passed in and out through slits suitably cut. By placing the box between the poles of a powerful electromagnet, the magnetic flux could be made to pass through one pair of coils and parallel to another pair. The electromagnet was gradually excited, and the induction through the sides of the box measured by a ballistic galvanometer; while the inductance of the coils across the flux was compared with that of the coils wound parallel to the flux by means of the secohmeter.

The measurements, several times repeated, all agreed in showing that the coils across the flux were most reduced in inductance as the flux itself increased; that is to say, the apparent permeability of the iron across the flux was the greater, the ratio being in fact about 2.5 to 1 at an induction of 11,000 C. G. S. lines per sq. cm. through the sides of the cube.

TABLE II.

Probable error of mean result. Kilometres.	Number of tests.	Percentage of probable error on inductance.	Ratio of bridge.	Temp. of bridge coils. Bridge correct at 19° C.
Wood....	2.27	0.041	0.9285	±0.0005	5	0.05%	1,000:10	27.3'C.
Wr'g't ir'n	2.28	0.734	167.5	±4.52	5	2.7%	10,000:100	"
Cast iron..	2.32	0.230	53.4	±0.7	5	1.3%	" "	"
Tool steel.	2.32	0.273	63.26	±1.7	5	2.6%	" "	"

On closer examination, however, a serious source of error became evident that ought to have been foreseen at the first. The lines of force issuing from the coil parallel to the flux could not be confined to paths intersecting the flux at right angles, and the many stray lines round the ends of the coils along the main path of induction produced an error in the measurements too great to be neglected, and too complex to calculate. The cube was, therefore, abandoned in favor of a more unexceptionable arrangement.



FIGS. 1 AND 2.

Four rings were then prepared, as shown in plan and diametral section in Figs. 1 and 2, of practically equal dimensions and rectangular cross-section, one of wood, the second of ordinary wrought iron, and the other two of cast iron and tool steel, respectively. The particulars of their dimensions are given in Table 1.

These rings were each wound with copper wire 0.036 cm. diameter, silk covered to 0.046 cm. in one complete layer of 289 turns, over oil paper. The weight of this layer was 18.5 grammes, and its resistance 2.2 ohms at 22° C.

The inductance of these solenoids was then measured with the following results, Table II, using a bridge, standard subdivided condenser, and secohmeter for reversals by a modification of Clerk-Maxwell's method.

The somewhat low degree of precision in these measurements indicated by the probable error is due to the difficulty so often met with in measuring the inductance of coils surrounding soft iron, with feeble testing currents. The precision increased however as the inductance lowered. The strength of the testing current in the above series was 29 milliamperes, at the maximum steady value, from which H would be 0.53 in each coil.

The rings were then placed in succession symmetrically between the poles of the above-mentioned electro-magnet, so that the magnetic axis apparently coincided with the axis of the ring. The polar faces were planes 7.3 cms. × 7.4 cms., and were kept apart 1.6 cm. by corner wooden wedges so as not to compress the ring. With the magnet unexcited, the inductance of the rings was found not to be sensibly altered by the presence of the iron poles, but on powerfully exciting the magnet, that of the three iron rings fell to quite a small percentage of its normal value, viz.: Wrought iron, to 20 per cent.; cast iron, to 13.8 per cent, and tool steel to 25.4 per cent.; the original values being restored on the cessation of the exciting current in the coils of the electro-magnet. The inductance of the wooden ring was quite unaffected, as might be supposed.

Steps were next taken to measure and control the amount of this magnetic flux across the ring, observing the inductance at each step. For this purpose, five turns of fine, insulated copper wire were wound on the external periphery of each ring, and five similar turns applied to the inner periphery by winding them on a closely fitted cork. The induction through these two windings at each stage of the magnetization was measured in the usual way by electro-magnetic reversal and ballistic galvanometer.

The difference between these inductions (slightly corrected for winding space occupied by the solenoidal coil),

being the total flux through the ring normal to its plane, the mean value of the induction per sq. cm. was immediately determined. The induction in the solenoid was similarly observed to make sure that no great error was involved by any want of accuracy in the alignment of the ring axis between the poles, this induction being of course with perfect alignment equal to that through one turn round the external periphery.

The results obtained in this way with each iron ring are given in tables III., IV. and V.

The exterior and interior turns were next removed, and a primary solenoidal winding of cotton-covered wire laid on each ring over the original layer now used as a secondary. This done, the rings were magnetized in the usual circular manner by measured currents through the primary coil, while the corresponding induction through, and inductance of the secondary layer, were observed at each step. This determined the inductance of the coil corresponding to each value of the magnetizing force and circular induction per sq. cm. The results with each ring are given in Table VI.

THE ELECTRICAL "AGEING" OF ALCOHOL.

After the crude material has been obtained, there are two stages in the process of preparing alcohol, namely, the rectification and the ageing. The method usually adopted for the latter purpose is to allow the spirit to remain several years in badly-corked barrels. This naturally involves the storage of large quantities of spirit, and to overcome this disadvantage M. Teillard has adopted the Broyer-Petit electro-chemical method at his distillery at Tournus. The principle of this process is to hasten the oxidation of the alcohol by exposing it to the action of ozone. To prepare the ozone two spirals of aluminium are arranged, one outside and one inside a perforated glass tube 1 cm. in diameter and 45 cm. long; around this tube is another one. The ends of the two spirals pass through the outer tube, and are connected to the terminals of an induction coil. Oxygen is sent through the inner tube, and is exposed to the influence of silent discharge between the two spirals. Great care is required in this operation. No spark must occur, and the temperature of the apparatus must not exceed 15° to 20° C., or the ozone will be destroyed. In actual practice the oxygen is passed through three such tubes in succession the induction coils being worked by a dynamo giving 3 volts and 6 amperes. By this means 10 cubic ms. (353 cubic feet) of oxygen is ozonized per hour. In addition to the dynamo, engine, and boiler, the complete installation comprises an oxygen gasometer of 20 cubic ms. capacity, six spirit vats, an oxygen pump, and an alcohol pump. All taps must be of wood, all tubes of glass, all plugs of cork, and the interior of the vats completely stripped of metal, owing to the energetic action of the ozone. In carrying out the process six vats are first filled with spirit. Oxygen is then passed from the gasometer over chloride of calcium to dry it, and is then passed through the ozonizers to a flask with three tubulatures, and thence through the six vats in succession to the condenser, where any vapor of alcohol taken up is deposited. The gas is then regenerated and used afresh. The volume of ozone required is about six times the volume of the alcohol treated, and the time required varies from five to six hours. Alcohol so treated is then stored in barrels, and after five or six months is ready for use.

ELECTRICITY IN PAPER MAKING.

For some time cellulose has been used in the manufacture of paper, but its extended adoption has been retarded by its high price. Dr. Kellner, Director of an Austrian cellulose factory, has, says the *Elektrotechniches Echo*, succeeded in reducing the cost by the following process: The shredded wool is put into lead-lined boilers with a 5 per cent. solution of common salt, which is electrolyzed for three and a half hours. The nascent chlorine bleaches the wool fibre to a snow-white silky substance. The operation is conducted at a temperature of 126 deg. to 128 deg. Centrigrade. The process is expected to have an important effect on the trade, as the paper made from cellulose is of particularly fine texture.

ELECTRICAL ENGINEERS.

CHARLES WILLIAMS, JR.

The subject of this sketch is unquestionably one of the pioneers of the telephone. Without him it is doubtful if even Prof. Alexander Graham Bell would have perfected his telephone. Without him it is almost certain the American Bell Telephone Company, now so rich and powerful, would have failed, or at least been obliged to struggle on much longer against adverse opinion and financial difficulties.

Mr. Williams began his electrical career in the "forties," soon after he entered into partnership with a Mr. Hinds, who did business as Hinds & Williams, dealers in and makers of electrical apparatus and supplies. This continued until Mr. Hinds retired, leaving the business to Mr. Williams. Soon afterwards, Prof. Bell met him and together they prosecuted experiments which resulted in a practical telephone line between his factory on Court street, Boston, and his house at Somerville, Mass. The first magneto call-bells and switch board devices were made at this place—crude and imperfect affairs—but they gave promise of usefulness and developed into satisfactory apparatus later. This factory supplied all the material for a long time, required by the National Bell Telephone Company, and Mr. Williams was for years the sole licensed manufacturer of this company. It was through the ownership of this company's shares, then looked upon with disfavor and suspicion, but probably the only available asset of the struggling company and taken with reluctance, that Mr. Williams acquired the bulk of his wealth. When value came to them, it came quickly and bountifully and a doubtful asset became a very remunerative one.

It was in April of 1877 that this first private line was built and used; and in May of that year the first public switchboard—made to connect a very few stations—was set up and operated at the store of E. T. Holmes, No. 342 Washington street, Boston.

C. Williams Jr.

Charles Williams, Jr.

It is not necessary to follow the growth and rapid development of the telephone system, but all who are familiar with the facts will readily concede the instrumentality of Mr. Williams in its successive stages. The "Williams" magneto call-bell and "Williams" switchboard remain to-day standards for excellence and utility.

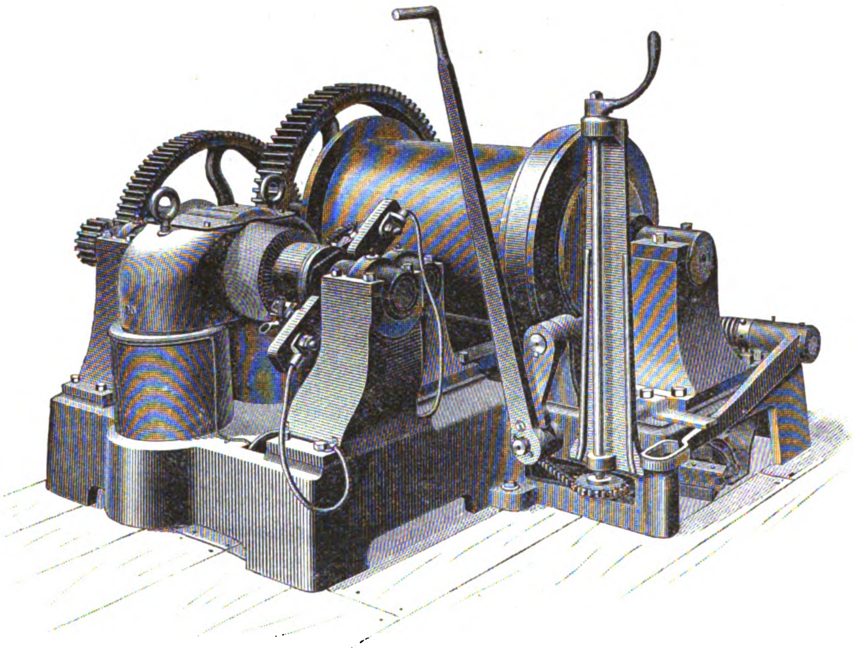
Mr. Williams retired from the field as licensed manufacturer for the American Bell Telephone Company in 1886, when it became necessary to start an independent and extensive workshop to supply the increased business of the country. This was done through the medium of the now celebrated Western Electric Company, whose factories in Chicago and New York are well known to every electrician and electrical engineer in the country. Mr. Williams remains to-day one of the largest individual stockholders in the Western Electric Co. He is also president of the Tropical American Telephone Co. He does not, however, deem it necessary to bestow close personal attention on his affairs, but has for some time past enjoyed a well earned leisure with his family in Berlin.

THE DAVIS ELEVATED ELECTRIC RAILWAY.

Mr. A. Davis, formerly of the North Shore Railway, has completed his plans for an elevated electric railway for Montreal, and has secured patents for the inventions which are the distinguishing features of the system. Mr. Davis in drawing up his plans has been guided by the conviction that it is necessary that any elevated road built in Montreal must be cheap and not injurious to the property along the route. He thinks that he has succeeded in meeting these requirements, as his system does not interfere with the light, is smokeless and noiseless and will cause no dust. The track is elevated on a series of single posts, 60 feet apart, and the structure altogether is said to be so light and ornamental that there can be no objection to it on the ground of unsightliness, urged so strongly against the elevated railroads in American cities. The posts are constructed in four sections, bolted together, so that a flaw can occur in one of the sections without endangering the whole structure. Single girders, resting on these pillars, and sunk six inches into their heads, carry the rails. Distinctive features of the system are the provision for supplying the motive power to the cars, and an extra safety appliance. The conductor conveying the current from the station runs along the top chord of the girder. The cross-ties, instead of being fastened to the top of the girder, are passed through the bottom of that piece of lattice work, so that the upper portion of the girder projects upward through the track bed to within an inch of the bottom of the cars. The upper chord of the girder, which carries the conductor, ends in a "T" iron. The motor is fastened under the center of the car, and the electricity is conveyed to it by two wheels, which grip the conductor and can be regulated from the interior of the car at will. The wheels are completely free from brake friction, as the brake system consists of a pair of shoes adjusted so as to grip the top chord of the girder on either side. The safety of the car is arranged by two slides passing freely under the top piece of the upper chord of the girder, and in case a wheel should break, the bottom of the car, having only one inch to fall before resting on the girder, would be firmly held in position by the safety guards. The motor can be made to work direct by steam, cable, or by electricity, which is the cheapest method. The plans provide for handsome cars and stations, the appearance of everything having been carefully studied. Mr. Davis estimates the cost at under $25,000 a mile all equipped, and he says he can get all the money necessary to carry out the undertaking if he can only secure a substantial contract. It will be interesting to see whether any work on his system is attempted. The time is ripe for it.

THOMSON-HOUSTON ELECTRIC HOISTS.

THE general applicability of the electric motor for power purposes compared with the steam engine is not better exhibited than in an installation which has just been put to work on one of the docks of Henderson Bros., agents of the Anchor Line S. S. Co., in Brooklyn. The use of the steam engine on docks where large quantities of cotton are handled, being considered extremely dangerous on account of danger from fire, the application of an electric hoist was therefore the only available plan, and it has been very neatly carried out by the Thomson-Houston Motor Company, who have supplied the apparatus shown in the accompanying engraving, but mounted upon wheels so that it can be easily transported from one part of the dock to the other and then connected to the leads which extend around the dock. The motor is of the same class as that employed for stationary work, except that it is series wound, the speed being regulated by a rheostat placed underneath a drum and controlled by a slight motion of the lever held in the left hand of the operator, which is so adjusted that the heaviest loads can be raised, lowered, or held without the use of the brake. The latter consists of an iron strip lined with wood and encircling the drum for more than three-fourths of the circumference. It can be applied by the simple pressure of the pinions. The gears are made of gun metal and run practically without noise, while the use of carbon brushes reduces the wear on the commutator to a minimum. The test which took place last week in the presence of a large number of gentlemen interested in shipping, was highly satisfactory, and we shall without doubt see many more applications of this kind in the near future. The work of installation was done under charge of Mr. H. C. Radford, of this city, who is the Thomson-Houston Motor Co.'s representative in N. Y. State. The next hoist which is to go in is to be slightly different in form, and is to have a higher speed. Mr. Radford devotes most of his time to this class of work, and firmly believes that the entire lading and discharging of vessels as well as the transportation of goods from the docks into the stores will eventually be done by means of electricity, and, from the success of his recent experience, we are inclined to agree with him on this subject.



THOMSON-HOUSTON ELECTRIC HOIST.

ELECTRIC TANNING.[1]

ON Wednesday, May 14th, the British Tanning Company, Limited, who own the British patents of MM. Worms and Balé, issued invitations to the members and press of the tanning, electrical, and allied trades, to inspect their works at Rothsay street, Bermondsey, and see the process of rapid electric tanning in operation. A considerable party of visitors, numbering nearly a hundred, were present, including several well-known tanners. They were first shown a drum containing tan liquor of the required strength, into which a pack of Australian salted hides, unhaired and cleaned in the ordinary way, were put. The drums employed are 11 feet 6 inches in diameter by 8 feet wide, and contain an electrode running round the interior of one end or head, from which the current passes through the liquor to a similar conductor on the other head.

The drum was set in motion, and a current of 10 amperes passed through the liquor. The action of the current which is applied is partly *to promote diffusion* and partly *to electrolyze the liquor*; both these effects, aided by the rotation of the drum, are no doubt the explanation of the remarkable saving of time effected by this process, it being possible thus to tan skins and hides in from 24 to 144 hours, against four to fifteen months by the old process of steeping in pits. A drum was opened which had been running for a little over five days, sections of the hides (salted Australian) were cut and examined by tanners present, and found to be thoroughly tanned. The visitors then inspected the drying sheds and shops above, where leather was seen in all stages, rolled for sole leather, curried, etc., also some hides prepared for machine belting. According to some tests shown us by Mr. Conrad Falkenstein, manager at Rothsay street, the tensile strength before breaking, taking the average from a number of samples, was equivalent to 4,305 lbs. per square inch for the electrically tanned leather, against 3,570 to 3,800 for leather tanned by the ordinary process. The leather is now being sold in the market, and is steadily taking its place in every branch of the trade. The company has an exhibit at the Edinburgh Exhibition, where samples of rough and dressed leather tanned by this process are on view.

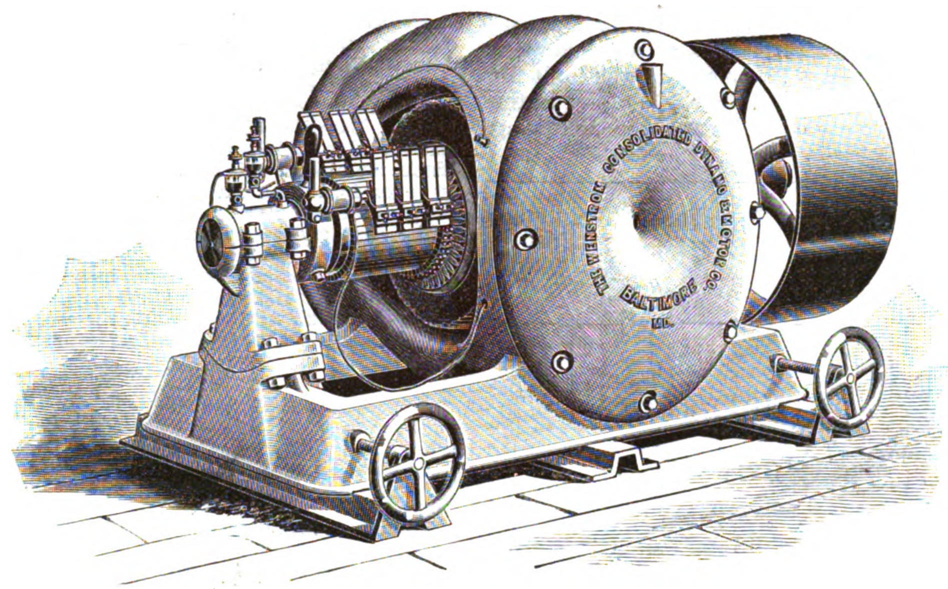
AN ELECTRIC ACOUMETER.

With a view of preventing fraud on the part of those who have been drawn for military service, and with whom partial deafness is a very common plea for exemption, Dr. V. Cheval, of Brussels, has brought out a modification of Prof. Hughes' sonometer, which he calls an electric acoumeter. The apparatus consists of three flat coils placed parallel to one another on a graduated rod passing through their axes. The centre coil is the primary and is fixed; the two outer coils are secondaries, and can be slid along the rod. The rod and coils are arranged on a board, on which there are an electrical tuning fork, a microphone, switches, plugs and other accessories. The individual whose hearing is to be tested is placed with his back to the apparatus, and has two telephonic receivers fixed tightly over his ears. Various sounds are then produced; the two outer coils being moved gradually away from the centre one until no noise is heard in the telephone receivers. The distance through which the coils have been moved is a measure of the hearing power of the individual. According to Dr. Cheval's investigations a person gifted with a fine sense of hearing ceases to hear the telephonic vibrations of a tuning fork on the left side when the coil is 435 mm. distant, and on the right side when the coil has been moved through 535 mm. For less sensitive ears the distances are respectively 293 and 401 mm. Deafness sufficiently pronounced to exempt from military service is represented by a distance of 100 mm. These distances, of course, are not absolute, and only refer to the particular apparatus employed in these researches.

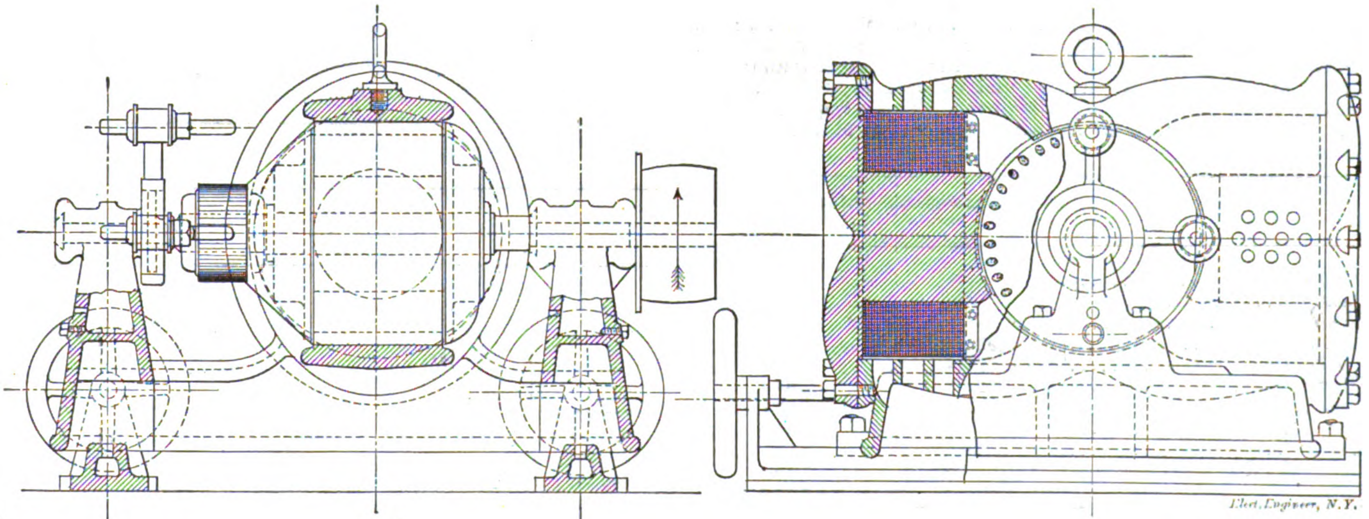
THE NEW WENSTROM DYNAMO.

Some years ago Mr. Jonas Wenstrom, a Swedish electrical engineer, brought out a type of dynamo, Fig. 1, in which the construction of the magnetic field as well as the disposition of the armature wires attracted considerable attention. The form of field adopted in this machine was what is now known as the iron-clad type, in which the magnetizing coils are surrounded by iron in all possible directions, in order that the iron core may collect practically all of the exciting force radiating from the coils. Evidently from this arrangement it follows that the exciting power may be less, all other things being equal, because the power is better utilized.



THE WENSTROM CONSOLIDATED DYNAMO & MOTOR CO.
BALTIMORE
MD.

Fig. 1.—The New Wenstrom Dynamo.



Figs. 2 and 3.—New Wenstrom Dynamo.

The machine in its improved form is now built by the Wenstrom Consolidated Dynamo and Motor Co., of Baltimore, Md., and the accompanying engravings, Figs. 2 and 3, show it in transverse and longitudinal section, respectively.

Usually the space between the magnet poles and core of the armature must be sufficient not only for the safe revolving of the armature at a high rate of speed, but also for the conductors, in which the currents are induced. This gap introduces a very high magnetic resistance in the circuit for the magnetic induction. To avoid this, therefore, the conductors are buried in grooves or holes.

The distance between the poles and the core is thus limited to the small gap required for the safe revolving of the armature. The magnetic resistance and the magnetic circuit is by this means reduced in a high degree, and consequently, the magnetizing power necessary for creating the required magnetism in the armature also decreased.

Some time ago a test was made by Dr. Louis Duncan, Dr. G. A. Liebig and Mr. W. F. Hasson, on a 400 ampere 110 volt dynamo of this type. The machine was built for 400 revolutions per minute, and weighed 7,100 lbs.; in the test it was run at 330 revolutions and gave the following results:

Current, amperes.	E. M. F., volts.	Horse-power.	Dynamometer, horse-power.	Loss.	Losses, friction reversals.	C^2 R.	Efficiency.
134.8	114.0	20.6	24.97	4.4	4.4	.17	82.5%
194.1	115.6	30.1	35.3	5.2	4.5	.52	85.2%
371.6	98.3	49.0	54.5	5.5	3.5	1.30	89.9%
400.0	110.0	58.9	64.7	5.8	4.1	1.50	91.0%

We may add that many of these machines are already in satisfactory use in this country.

ON THE HEATING EFFECTS OF ELECTRIC CURRENTS.[1]

BY WILLIAM HENRY PREECE, F. R. S.

THE effects of the heat developed in conductors when electric currents are transmitted through them have been the subject of constant investigation on my part since 1878. In 1880 I found that the rapidity with which small bare wires acquired higher temperatures and lost them in air was so great that it was possible to reproduce sound and speech by means of the thermo-telephone (*Roy. Soc. Proc.*, No. 204, 1880).

I determined subsequently (*Roy. Soc. Proc.*, No. 231, 1884) the current that raised the temperature of small conductors in air to the fusing point, and proved experimentally that, while bare cylindrical wires of very small diameter did not follow the $d^{\frac{3}{2}}$ law, this law became rigid for all diameters above 1 mm.

Papers *Roy. Soc. Proc.*, November 24, 1887, and March 15, 1888, dealt principally with the fusing points, and the following table, to which I have added silver, gives the fusing constants for all the metals in general use when bare and exposed in still air. The numbers indicate the current in amperes which is required to fuse a cylindrical conductor of a diameter of 1 cm. of the material named.

	Fusing constant. (a).	Fusing temperat're C°.
Copper	2530	1054
Silver[2]	1900	954
Aluminium	1873	650
German silver	1292	1200
Platinum	1277	1775
Platinoid	1173	1300
Iron	777.4	1600
Tin	405.5	226
Lead	340.6	335
Alloy (lead 2 parts, tin 1 part)	325.5	180

I have added the temperature of fusion to each of these metals, and the table means that if we take, for example, a uniform copper wire of 1 cm. diameter, a current of 2530 amperes will raise it to 1054° C., and therefore fuse it; and if we take any similar conductor of copper, but of different diameter (d), the fusing current (C) is

$$C = 2530\, d^{\frac{3}{2}}.$$

The fusing current of any other material is obtained from the equation.

$$C = ad^{\frac{3}{2}}.$$

It seemed natural that these constants, marking such a distinct and well-defined fiducial point, should also enable us to obtain the currents that would raise the wire to any other temperature.

A constant current traversing a cylindrical metallic conductor does work (W) upon that conductor to an amount which is measured per second by the product of the electromotive force (E) at the ends of the conductor and the current (C), or

$$W = E C.$$

This work appears as heat. The temperature of the conductor is raised. When the temperature of the wire becomes constant the expenditure of energy in the wire, and its dissipation by radiation and convection from the surface of the wire, must be equal and constant also. Hence the temperature of the conductor when constant becomes a measure of the work done per second, and therefore a measure of the constant current flowing. The rate of loss of heat per degree per unit area of any surface is its emissivity (e). The value of e depends upon the character of the surface, that is, whether it is polished or rough, clean or dirty, bright or black, metallic or oxidized, painted or coated with some preservative or insulating medium. For the present we will consider an unprotected surface comparable with the surface when at white heat, and we will call that surface *normal*. Let a current be applied to a given conductor, exposed in still air at atmospheric pressure, until it assumes any constant temperature (T), the surrounding objects being at a lower temperature (T_1); then the total heat (W) which will be emitted per second by the whole surface (S) of the wire to the surrounding objects will be

$$W = e\mathrm{S}\,(\mathrm{T}-\mathrm{T}_1).$$

Hence $$EC = e\mathrm{S}\,(\mathrm{T}-\mathrm{T}_1) \qquad (1),$$

or $$e = \frac{EC}{\mathrm{S}\,\theta},$$

if we put θ for $\mathrm{T}-\mathrm{T}_1$, the excess of temperature acquired by the wire.

Hence we can determine e for any conductor at any temperature by measuring EC and θ.

Putting $E = CR$, $\mathrm{S} = l\pi d$, and $R = 4\rho l/\pi d^2$ (ρ being the specific resistance in C. G. S. units, l the length, and d the diameter in centimetres), (1) becomes

$$4C^2\rho = e\pi^2 d^3\,\theta,$$

and $$\theta = \frac{4C^2\rho}{e\pi^2 d^3} \qquad (2.)$$

Now, if ρ and e vary together in the same proportion in terms of θ, then $\theta = \kappa C^2$ for any particular wire. That ρ and e do vary together in the same proportion is entirely in accordance with measurement and experiment; and it is interesting to note that it is also in accordance with the researches of Mr. J. T. Bottomley on thermo-radiation (*Phil. Trans.*, vol. 178 [1887], A, pp. 429–450). Thus, if we take the table given on p. 443 of that paper, and work out the variation in resistance of a platinum wire (which variation is the same as for copper) by the usual formula,

$$R_t = \mathrm{R}_0\,(1.0038)^{\theta},$$

we get the values shown in the fourth column :—

Bottomley's researches.			R_t calculated from the formula $R_t = 14.5 \times (1.0038)^{\theta}$.
θ.	C^2/RJs.	e.	
65°	9.45×10^{-4}	14.5×10^{-6}	14.5
110	20.53 "	18.7 "	17.2
232	74.7 "	32.2 "	27.8
383	236 "	61.6 "	48.4
740	1468 "	198 "	187.6
900	3218 "	358 "	344.2

If we determine C for any temperature, then, since $\theta = \kappa C^2$, the current C' producing any other temperature θ' is obtained by means of the equation

$$C' = C\sqrt{\frac{\theta'}{\theta}}.$$

Now, for copper of 1 cm. diameter $C = 2{,}530$ for 1,054°. Thus, if we want to find the current that will raise such a conductor to 13°, we have

$$C' = 2{,}530\sqrt{\frac{18}{1{,}054}} = 281 \text{ amperes},$$

if the surface be equivalent to the assumed normal surface.

Now, since we are dealing with metallic surfaces only, and the normal surface has been defined to be that comparable with the surface when at a white heat, it remains for us to determine the coefficient which shall convert this normal surface emissivity to that of the surface of ordinary wires at low temperatures. This I have done for copper, and the results have been amply confirmed by Mr. Kennelly, in Mr. Edison's laboratory at Orange, N. J., U. S. A.[3]

---

[1] A paper read before the Royal Society, May 9, 1890.

[2] G. Roux, *L'Electricien*, December 14, 1889.

Taking the normal surface as unity, then

	Surface coefficient.
Bright and polished copper	0.5
Copper, dirty, oxidized, or blacked with shellac varnish	0.6
Copper, well coated with lampblack	1.0

Taking a wire 1 cm. in diameter and calculating from $C' = 0.5C\sqrt{\frac{\theta'}{\theta}}$ for bright wire, and $0.6C\sqrt{\frac{\theta'}{\theta}}$ for black wire, we get a concordance which is very satisfactory.

5°.				10°.				20°.				40°.				80°.			
Bright		Black.		Bright		Black.		Bright		Black.		Bright		Black.		Bright		Black.	
P	K	P	K	P	K	P	K	P	K	P	K	P	K	P	K	P	K	P	K
87	85	104	104	123.2	120	148	147	168	169	201	207	243	236	291	290	350	329	420	410

N. B.—"P" means calculated from the formula $C' = 1265\sqrt{\frac{\theta'}{\theta}}$, and "K" means the figures obtained by Mr. Kennelly.

Now, the current (C) producing 1,054° (θ) in a bare bright copper cylinder of 1 cm. diameter is 0.5×2.530 amperes, and that which would produce a temperature of 10°C. is

$$0.5\times2{,}530\sqrt{\frac{10}{1{,}054}} = 123.2 \text{ amperes.}$$

Using both alternating and continuous currents, it was found that in a copper wire with $d = 0.6956$, θ was 50°.3. Now the current (C') that will raise a wire 1 cm. in diameter 50°.3 in temperature is

$$C' = 2{,}530\sqrt{\frac{50.3}{1{,}054}} = 552.7 \text{ amperes.}$$

But the current that will raise a wire of a diameter of 0.6956 cm. through the same temperature is

$$(C \times d^{\frac{3}{2}}) = 552.7 \times .6956^{\frac{3}{2}} = 320.6 \text{ amperes;}$$

or, if the wire be dirty,

$$320.6 \times .6 = 192.4 \text{ amperes.}$$

The current actually was in each case 198 amperes.

A copper conductor, bare and dirty, 20 feet long and 0.415 in. in diameter, was stretched across a room where the air was still, and various continuous currents were transmitted through it. The results are tabulated, and the observed and calculated currents given.

Time.	Increase of temperature of wire. C.	Current in amperes.	
		Observed.	Calculated. $C' = 0.6\,C\sqrt{\frac{\theta'}{\theta}}\,/\,d^{\frac{3}{2}}$
10.45	—	454	—
11.15	86°	454	467.7
12.0	80	450	451
3.30	79	445	448
3.45	78	440	445
4.30	73	429	431
Current stopped; wire cooled. Current put on again at 5.30.			
6.0	38	290	310

Thus, if we know the current producing any fixed temperature in any cylindrical conductor, we can readily calculate the current required for any other temperature.

MEETING OF THE WESTERN GAS ASSOCIATION.

The Western Gas Association held its thirteenth annual meeting at St. Louis on May 21–23. In the course of his address, Vice-President C. R. Faben, Jr., of Toledo, O., said:—

The past year has not been rich with startling developments of new types of apparatus, nor radical changes in existing plans of operation; yet we have progressed. We have improved in many small matters of detail, and have progressed toward that goal that we call perfection. We have dismissed a large measure of the prejudice that formerly molded many of our expressed convictions, even though we may have held at the time an honest opinion to the contrary, yet, on account of our prejudice, we would not give it expression in our utterances.

Water gas is one subject that clearly illustrates to what extremes our prejudice may lead us. The successful application of electricity as a source of light is another. To-day we speak of and regard these projects in an entirely different manner than formerly.

Electric Light.—The electric light as a competitor to gas, for purposes of light, presents a solid front. The arc light has established itself as the best means of lighting large areas, and for street lighting purposes it has no equal. The incandescent electric light is making good, fair progress in many places, and I might say generally. It presents some few advantages over gas that the promoters never fail to appreciate, and they always call the attention of possible patrons to these various little advantages. A naked flame is a dangerous thing to have exposed in many situations that gas jets have been used, and with the incandescent electric lamp quite a display is often made in show windows, stores and private houses, with the light placed and distributed in some unusual manner, the effect of which is novel and at once taking to the average person.

How very profitable to investors these electrical undertakings may be, I question. From statements recently made I find that out of about 100 electric lighting companies in Massachusetts only 15 declared dividends in the past year. Of these 15 companies 10 declared dividends of from 1 to 6 per cent., and only 5 declared dividends above 6 per cent. Leaving out the Boston companies, which by reason of the extent and value of their territory enjoy a greater demand for their light than exists in smaller places, the average of dividends paid by the electric light companies in the State, who paid dividends at all, has been only 4.9 per cent.

Another fact in this connection is that no fund has been created by these several electric light companies to compensate for wear and tear. No depreciation has been charged off. The usual and necessary repair is supposed to represent all of the depreciations, so that the dividends paid are virtually taken from the plant itself or its value. Electric light companies are opposed to having any depreciation charged off other than the cost of repairs and renewals actually made.

The use of the incandescent electric light has demonstrated to my mind the tendencies of the times in the matter of distribution of light. A few years ago many consumers of gas complained of the light produced from burning gas, that it was not of sufficient intensity, and they resorted to the arc light. In many of these situations since that time the arc light with all of its intensity and other desirable qualities has been discarded, and a great number of incandescent electric lamps are used in its stead, so that the present tendency seems to be in the direction of the use of a large number of small lights for indoor illumination, giving to the general illumination something more of a starry effect.

The custom or practice with incandescent electric light companies, in the matter of computing and establishing rates for lighting service, is certainly faulty. No matter how careful and conscientious a consumer may be, the privilege to the free and unlimited use of an article of light leads to great wastefulness. This wastefulness is an item of expense to some one, and, under the conditions cited, it must be a very serious item to the producer. The question of whether or not gas light companies should engage in the supplying of electric light is a purely business proposition, and is determinable only by local conditions. In some situations, yes; in others, no.

THERMO-MAGNETIC APPARATUS.

The two following pieces of laboratory apparatus have been devised by J. Stefan to exhibit thermo-magnetic phenomena. The first, a thermo-magnetic pendulum, consists of a nickel segment attached to the end of a strip of brass, which is movable round a horizontal axis, and is provided above this axis with a sliding weight. When at rest the nickel segment lies between the poles of a horse-shoe magnet. On heating one end of the segment, however, that end immediately moves upwards, and if the heating is continued a regular oscillation may be started. The second piece of apparatus is merely a nickel disc which can rotate around an axis passing through its centre of gravity. The poles of a horse-shoe magnet cover a portion of the rim, and on heating another portion the wheel commences to rotate, and under favorable conditions can be made to revolve at the rate of 60 revolutions a minute.

---

[3] A. E. Kennelly "On the Heating of Conductors by Electric Currents." (Abstract of report read before the Edison Convention at Niagara Falls, August, 1889. *Electrical World*, Nov. 23, Nov. 30, Dec. 7, and Dec. 14, 1889).

STANDARD SPECIFICATIONS FOR ELECTRICAL PLANTS.

THE new catalogue just issued by the United Edison Manufacturing Company, besides containing an excellent description of the Edison apparatus and a large number of testimonials as to the merits of the system, embodies a form of standard specifications for electric light plants. These specifications, which we print below, are evidently the result of a large experience in this class of work, and show the high standard adopted by the Edison Company in its installations :

Dynamos.—The dynamo must be of such type and must be so connected as to operate with the highest economy, either separately or in multiple arc (in case there be more than one dynamo), and so that in such case the load may be shifted from one machine to another up to the limit of its full load without in any way affecting the candle-power of the lamps. The dynamo must be capable of being operated for ten hours continuously under conditions of full rated load without injurious heating of any part of the dynamo and without sparking. The dynamo must be of such design that the increase in power required to operate it from least load to full load shall be proportional to the number of lamps in operation. The dynamos must have a commercial efficiency under full load of not less than 85 per cent. in dynamo, requiring three (3) horse-power in belt, and of not less than 92 per cent. in dynamo, requiring one hundred (100) horse-power; and dynamos of intermediate size shall have an efficiency proportional to the efficiencies quoted. The commercial efficiency of the dynamo under conditions of one-quarter load shall not vary more than 8 per cent. from that at full load. Each dynamo must be provided with a belt tightener, so that the tension of the belt may be altered at will while machine is in operation. The armature of the dynamo shall be perfectly balanced, so as to run at its rated speed without appreciable jar. There shall be at least two brushes on each side of the commutator. The insulation resistance between the armature and field coils and the base of the machine must be at least 200,000 ohms. Each dynamo must be placed on a solid wooden base, and must be thoroughly insulated electrically. (When operated continuously for ten hours under conditions of full load, the temperature of no insulated wire or other electrical portion of the dynamo shall rise in temperature more than eighty degrees C. above the temperature of the surrounding air.) All dynamos shall be provided with self-oiling bearings, which, under normal conditions, shall not require attention, except when the dynamo is started.

Instruments.—Each dynamo must be provided with an ampere meter in circuit with it, which shall show continuously the current said dynamo is producing. These ampere meters must be constant, unaffected by any normal change in temperature and unaffected in their readings by being placed at a distance of six feet or more from the dynamo. The ampere meters must be accurate within 3 per cent.

A pressure indicator shall be furnished for each dynamo or set of dynamos operating in multiple arc. This pressure indicator must be connected so as to indicate directly and continuously the electrical pressure at the point to which it is connected. It must be constant in its readings, unaffected by normal changes of temperature, unaffected in its readings by magnetic influences at a distance of ten feet from a dynamo, and must be so constructed that a variation of one volt will cause a deflection of the pointer upon the scale readily noticeable at a distance of ten feet from the indicator.

A ground detector shall be provided which will indicate continuously the condition of each pole of the system as regards insulation to ground.

Incandescent Lamps.—Lamps furnished must be guaranteed to have an average life of six hundred (600) hours and a corresponding economy of fifteen (15) lamps to the electrical horse-power. All lamps shall be of such uniformity when new that when operated at the voltage for which they are intended, both the power required and the candle-power of the lamp shall be within ten (10) per cent. of the rating. All lamps which give out from any fault within the first ten hours of the operation of the plant, shall be replaced by others without charge. All breakage of lamps beyond this, under normal operation of the plant, shall be considered under the guarantee as to average life. Lamps shall be furnished varying in candle-power from sixteen (16) to one hundred (100), there being at least three (3) different candle-powers between sixteen (16) and one hundred (100). Lamps of different candle-power shall require power in proportion to their candle-power.

Pole Line.—The pole line shall be composed of straight, select, shaved poles. All poles must be set perpendicularly, and must be thoroughly guyed, whenever necessary, to insure this result. They must be set one sixth of their length below the surface of the ground. All poles must measure, at least, five inches in diameter at top, and where more than one cross-arm is required, they must measure not less than six inches in diameter. They must be housed and gained. All cross-arms shall be thoroughly seasoned and free from knots, and painted. All cross-arms must be secured to poles in substantial manner, so that they shall be at right angles with line of pole and parallel with each other, and accurately fitted into gains. All poles where cutouts are placed shall be stepped. The poles shall not, under any circumstances, be set further apart than one hundred and fifty (150) feet, and in heavy line work they shall not be set more than one hundred (100) feet apart.

Overhead Conductors.—The overhead conductors shall be of bare copper in systems using less than five hundred (500) volts. The pressure lines and service lines shall be insulated by weather-proof insulation. Whenever the conductors are likely to make contact with other materials than the insulators or poles (except leaves) the conductors shall be properly insulated therefrom. No overhead wire having a span of over ten feet shall be run in closer proximity to any other wire than ten (10) inches. All joints shall be made in substantial manner, so that no movement of the two ends relative to each other is possible, and so that the joint is as strong as the wire itself and makes thorough contact All joints must be soldered. All overhead conductors exposed to influence of atmospheric electricity shall be protected therefrom by suitable lightning arresters.

In all cases where other wires are run above the conductors under consideration, a guard wire must be run to protect the latter from contact with the former.

Wiring and Wiring Devices.—For convenience in reference the wiring will be treated under two heads, the supply wires and the distributing wires.

No distributing circuit shall carry more than five (5) amperes. The distributing circuit shall lead from the distributing cut-outs, which shall be grouped together in cut-out cabinets at various distributing points in the building. Any doors, locks, hinges, etc., if desired for these distributing cut-outs, shall not be furnished by this contractor, but the cut-out cabinet shall be prepared ready for them by the contractor. The maximum loss in any distributing circuit not to exceed two (2) per cent. The cut-outs at each distributing point to be supplied by mains, which mains shall be so proportioned that under any conditions of normal load there shall not be a variation of pressure throughout the mains to exceed two (2) per cent. The connection to the distributing cut-outs from the mains shall be made through double pole fusible cut-outs of proper dimensions. In case current be supplied to the mains through feeders, there shall be fusible cut-outs placed at the points where the feeders join the mains, such cut-outs being placed both at the terminal of the feeder and upon the main immediately on both sides of the feeding point. All lines leaving the dynamo room shall be protected by fusible cut-outs, and in addition thereto any wire leaving dynamo room and carrying a current of more than five (5) amperes shall have a switch in circuit with it. In all molded or concealed wiring where insulation of the wire makes contact with material other than special insulating material designed for the purpose, a wire of following makes, or equally as good grade and acceptable to the purchaser, shall be used : Edison Machine Works, Grade 3, Habirshaw, Okonite, Grimshaw, Kerite, Clark Safety Insulator. In the case of cleated work, where the wire will never, under normal conditions, be exposed to any moisture, an insulation of the quality known as weather-proof can be used, such as the following or their equivalent : Edison Machine Works, Grade 1, P. & B., K. K., Roeblings' Weather-proof, Ansonia Brass and Copper Co.'s Weather-proof. In all work in connection with the wiring, the wire must invariably be handled so that if the wire were bare the insulation would be the highest possible under the conditions. In other words, the insulation must not be relied upon any more than is absolutely necessary. No wire smaller than No. 18, Birmingham Wire Gauge, or No. 16, Brown & Sharp's Gauge, shall be used. In all cases the ampere capacity of the conducting wires must be carefully determined, and the size of the wires so proportioned that the maximum current carried by them under normal conditions shall not occasion a rise in temperature exceeding sixty (60) degrees Fahrenheit. The wiring must be done in such a manner that in case a different system be used from that originally contemplated, there will be the least possible expense involved in changing the wiring to adapt it to any other system. All joints must be made in substantial manner, so that no movement of the two ends relative to each other is possible, and so that the cross-section of contact is at least twice the cross-section of the conductor. All joints, except when surfaces are held in contact by strong pressure, such as by screws, shall be well soldered and well taped. In all cases where the wire is concealed from view the joints shall be thoroughly covered with some first-class waterproof compound before being taped. All wires that pass through floors or that rest against any metal work shall be protected by a tubing of hard rubber extending at least one inch in each direction beyond such floor or metal work. With all safety devices open, the insulation of any single section of the wiring shall not be less than 100,000 ohms. The combined insulation resistance, when all sections are connected up for service, shall be the highest obtainable when each section measures 100,000 ohms. Metallic staples for fastening wires shall not be used unless there be placed between the insulation of the wire and the staple some insulating and non-combustible material. Electric light fixtures or gas fixtures carrying electric light wires, if attached to gas pipes, must be insulated therefrom by insulating joint or other suitable means, so that there shall be a high electrical resistance between such electric light wiring, such fixtures and the system of gas pipes. The wiring must be so proportioned that the maximum variation of electrical pressure at the lamps in different parts of the building under any normal conditions shall not exceed two (2) per cent. All wiring must be neat in its mechanical appearance and arrangement. All points in regard to wiring not above specified shall conform strictly to the requirements of the National Board of Fire Underwriters. All cut-outs shall be made of insulating and non-combustible material, such as porcelain, glass, etc., and shall be double poled. All switches shall be mounted upon insulating and non-combustible bases, and if covered, shall be so designed that the switch is merely set by hand ready for the break in contact, and the actual breaking of contact shall be done automatically and beyond hand control. The act of making and breaking contact in all switches shall cause the surfaces in contact to be subjected to sliding friction in order to keep such surfaces of contact clean. All sockets shall be of same dimensions relative to the base of the lamp, so that any standard Edison lamp of any candle-power will fit any socket. The socket shall be of substantial, workmanlike construction, and all portions of the shell and key shall be thoroughly insulated.

ON AN ACCIDENTAL ILLUSTRATION OF THE EFFECTIVE OHMIC RESISTANCE TO A TRANSIENT ELECTRIC CURRENT THROUGH AN IRON BAR.[1]

BY SIR WILLIAM THOMSON.

The wonderful accidental experiment of Lord Armstrong may briefly be described as follows:—A bar of steel which Lord Armstrong was holding in his hand was allowed accidentally to come in contact with the two poles of a dynamo giving 85 amperes and 103 volts. A painful sensation of burning was instantly felt and the bar was dropped. Severe blisters occurred where the hand or the fingers touched the bar, which was found immediately afterward to be quite cold, or not perceptibly hot. This marvelous incident proved: (1) the outer surface of the steel to have been intensely heated; (2) that not enough heat was generated to sensibly warm the whole bar. The explanation, of course, is to be found in the known laws of diffusion of electric currents through non-magnetic conductors, considered in connection with the effect of magnetic susceptibility, of unknown amount and law, in conductors of steel and iron.

The requisites for working out fully the theory of transient or periodic currents in conductors of any form are included in Maxwell's fundamental equations, and are given explicitly for straight cylindric conductors of non-magnetic material in sections 685–689 of his work. Lord Rayleigh, in his paper "On the Self-Induction and Resistance of Straight Conductors" (*Phil. Mag.*, May, 1886), gives the formula for transient or periodic currents in straight cylindric rods of iron, on the supposition of constant magnetic susceptibility. The details of this highly interesting and important branch of the subject have also been investigated by Heaviside in a very comprehensive manner. The tendency of periodically alternating currents to be condensed on the outer part of a cylindric conductor, while the current may be exceedingly feeble or quite insensible in the central parts, was discussed and explained by Lord Rayleigh in page 388 of his article already referred to, and its aggravation in an iron conductor specially pointed out. The same considerations show that a transient current resulting from the application, for a very short time, of the electromotive force of a voltaic battery, or of electro-magnetic induction acting not directly on the cylindric conductor considered, but on a conductor such as the inductor of a dynamo of any kind, momentarily in circuit with it, is only skin deep if the duration of the electromotive force be but short enough; and that the depth to which the current penetrates in a given very short time is much smaller for iron than for copper.

THE NON-CONDUCTIVITY OF A VACUUM.

In a recent paper in Wiedemann's *Annalen* on "The Electrical Conductivity of Gases," T. Homen denies the validity of Foeppl's so-called experimental proof of the non-conductivity of a vacuum described in vol. xxxiii. of the *Annalen*. Homen points out that the length of path to be traversed by the discharge in Foeppl's experiment must have been at least 13 metres. Now, his own recent experiments show that in an electrical discharge through rarefied gas there is an addition to the true ohmic resistance, a resistance of the nature of a counter E. M. F., and for a length of path of 13 metres, and a pressure equivalent to 0.09 millimetre of mercury, the value of this counter E. M. F. would be about 5,200 volts, and as at this pressure the counter E. M. F. diminished as the pressure increased, it would probably be greater for higher vacua. The E. M. F. of about 270 volts employed by Foeppl could not, therefore, be expected to produce a discharge.

DEATH OF CARL FRISCHEN.

The death is announced on May the 8th., of Herr Carl Frischen chief engineer to Messrs. Siemens and Halske, of Berlin. He was born at Bremen in 1830, and apprenticed at an engineering works in that town, subsequently studying at Hanover. He afterwards entered the service of the Hanoverian Government, and in spite of his youth was entrusted with the superintendence of the erection of railway telegraphs, and shortly afterwards he was appointed chief of the Hanoverian telegraphs. In that capacity he was the inventor of numerous practical arrangements and improvements. In 1856 Herr Frischen invented a duplex telegraph simultaneously with Herr Werner Siemens, and in that way his name became more widely known. In 1867 Herr Frischen entered the telegraph service of the North German Confederation, and for some years held in Berlin the office of chief telegraph engineer, but afterwards, in 1870, accepted an offer of Messrs. Siemens and Halske to enter their service as chief engineer. His inventive capacity, combined with his practical turn of mind, found full scope in the large and diversified works of the firm, extending to all branches of electricity. About four years ago his health suffered from the effects of a serious operation, and although appearing restored a fatal result has unfortunately ended an interesting and useful life.

VERIFYING THE PHENOMENA OF ELECTRIC REPULSION.

The important task of verifying some of Prof. Thomson's results by careful measurement has been undertaken by M. Borgmann, who, in a number of the *Comptes Rendus*, describes several quantitative results he had obtained. The primary magnetizing current was measured by a Siemens dynamometer, and the repulsive forces exerted on a disc were weighed by means of a delicate balance. The repulsive force was found proportional to the mean square of the primary current; it diminished as the distance between the disc and magnetizing solenoid increased; it diminished with the diameter, and increased with the thickness of the disc. For discs of the same dimensions, but of different metals, the repulsion diminished with the specific resistance, although in a less proportion, owing to self-induction; and, as the frequency of the current was increased, the forces were found to diminish, the product being about constant. Although several of these results are only what theory would have predicted, it is the first time they have been experimentally shown.

BOILER CLEANING BY MAGNETISM.

At the 10th Annual Convention of the American Water Works Association, recently held at Chicago, Mr. Bull, of the Committee on Electrical Boiler Devices reported the results of the experiments made by him to obtain a method of overcoming the scale in boilers by the employment of magnetism. The first apparatus used by him consisted of an electro-magnet attached to the mud drum of a boiler; another electro-magnet attached to the feed drum; and an iron yoke connected to the two magnets, which magnets were excited by a small dynamo. His first theory regarding the action observed was that the operation was a mechanical one, the result of a rapid polarization and depolarization of the boiler by means of an interrupted or alternating current setting up something like a vibration in the shell and tube, which prevented a lodgment of scale upon their surfaces, the mineral being kept, as it were, dancing like a grain of sand upon a vibrating plate.

Having heard of the experiments of Mr. Frazer, who aged wine by means of the application of magnetism in California, he saw fit to change his views and modify the construction of his apparatus accordingly. One of the changes made by him consisted in the substitution of permanent steel bar magnets in place of the electro-magnets as a source of magnetic energy. In the present type of apparatus, the magnets are ranged within a cylinder in sheets and bundles. They are made of plate bars of hard steel and are somewhat separated to permit of an uninterrupted passage of the feed water. In a cylinder of 10 inches in diameter there are about 150 magnets made of ¼ inch steel, 1 inch in width and of varying lengths from 3 to 10 centimetres.

A test was recently made on a boiler in a lime burning establishment near Quincy, Ill., the boiler in question being fed from a well at the edge of a limestone quarry. The water was perfectly clear to the eye, free from organic matter and all visible impurities, but chemical tests showed it to be one of unusual hardness. It was, in fact, so bad that the tubes in this particular boiler are renewed twice a year on account of the scale which forms on them. It was a fact that in ten days a heaping shovelful of sand or disintegrated scale was taken out, and after a few more weeks not less than three shovelfuls of the same were removed, mixed with fragments of friable scale.

Prof. A. R. Leeds, of the Stevens Institute of Technology, Hoboken, discussing the paper of Mr. Bull, called attention to the fact that about twenty-five years ago, the Franklin Institute had experimented in this direction and had obtained promising results.

---

[1] Abstract of paper read before the Royal Society of Edinburgh, March 17th, 1890.

That for some reason the promises had not been fulfilled and the matter had been dropped. The plan then in use was to fix permanent magnets to the crown sheets of the boilers and connecting them by wires to the forward end of the boiler.

CORRESPONDENCE.

BOSTON.

Captain Brophy in the West—West End Increase—N. E. Electric Exchange—Thomson-Houston Stock.

CAPT. BROPHY is making an extended trip through the West, examining electrical risks for the Electric Mutual. His trip has covered a period of over six weeks, and he has inspected over 50 stations.

The West End Street Railway Company are still continuing to increase their facilities, and have applied to the selectmen of Brookline for permission to erect a car house on Chestnut Hill avenue.

Mr. H. C. Spaulding, of the Thomson-Houston Electric Co., has been elected treasurer and secretary of the N. E. Electric Exchange, vice H. H. Fairbanks of Worcester, resigned. Mr. Fairbanks takes the seat at the board vacated by Mr. Spaulding in his acceptance of the treasurership.

Application has been made to list the negotiable receipts issued by the American Loan and Trust Co. for Thomson-Houston stock deposited under the circular of May 26. It is reported that about 75 per cent. of the stock has been deposited with the American Loan and Trust Company.

The West End elevated road bill has been taken up again this week by the legislature, and a number of amendments acted upon. The house adopted an amendment giving the board of aldermen authority to grant the location for the elevated tracks, with the approval of the Mayor, and the assent of the railroad commissioners. Other amendments of greater or lesser importance were also adopted, but no definite result has yet been reached in the main question, and the bill has been passed to be engrossed. The Meigs bill has been enacted without debate. Mr. Howland, of Chelsea, moved a bill as a substitute for an adverse report on allowing cities and towns to make and sell gas and electricity. To his bill he offered a further section that, "If in any city or town there exist at the time of the passage of this act, gas or electric light plants, owned or operated by persons or corporations acting under the laws of this commonwealth, such plants shall be purchased by said cities and towns," in the manner provided in the bill before they go into the business themselves. The price paid for the property is not to include the value of the franchise or of any privileges, but only the cash value of the property, to be fixed by three persons selected in a specified way, their decision to be final when accepted by vote of the city or town.

Speaker Barrett appointed Messrs. Hildreth of Holyoke, Sandford of Boston and Lyons of North Adams (each of whom is on record against the bill) as a committee of conference on the bill for the consolidation of gas and electric light companies.

BOSTON, June 7, 1890.

ST. LOUIS.

Electric Railway Work—Names of Streets on Lamp-posts—The Municipal Company's Station.

THE following bills have been introduced before the Municipal Assembly for electric railway privileges.

The St. Louis Cable and Western ask for the privilege of equipping with electric power east of 23d street. They already have an ordinance for equipping west of 23d street.

The Southern Railway ask for the privilege of constructing a branch from Seventh and Ann avenues to Tower Grove Park, the same to be operated by electric power.

The Southwestern Railway and the St. Louis and Suburban Railway, two new schemes, asked for the privilege of constructing electric roads.

The Laclede Gas Company having removed their gas lamps from the streets, the city is left without street names, and the Board of Public Improvements are considering devices for street nomenclature, one of which is to purchase or lease of the gas company such lamp-posts as may be required and light them with small incandescent lights.

The track laying and wiring of the down town section of the Union Depot Railroad Company will be finished and electric cars will be running to Fourth and Pine streets early this month. This will be the first electric railway to reach the down town district.

The Municipal Electric Lighting and Power Co. will hold their annual meeting for the election of officers on June 2d. The mammoth station of this company attracts widespread interest. The Western Gas Convention during their stay in the city, visited the station almost in a body. The officers of the Evansville Gas Co. also made a visit to the station.

ST. LOUIS, June 4, 1890.

PITTSBURGH.

Electric Railway Work—Electrical Litigation—Westinghouse Plans.

The St. Clair electric road of this city has put several new cars on its line for the accommodation of the enormous increase in the patronage of the road.

Mr. James Hunter, of the Allegheny County Light Company, addressed a large meeting of stationary engineers the other day on the subject: "The alternating current system for incandescent and arc lighting and the direct current for motor service." The address was made in the rooms of the National Association of Stationary Engineers.

At a meeting of the Councils of Braddock, Pa., W. F. Cook, Esq., of Pittsburgh, as the representative of a street railway company, made a petition before that body to obtain the right of way through the borough for an electric street railway to Wilmerding. The latter place is a new town founded by Mr. George Westinghouse, Jr., where the new shops of the Westinghouse Air Brake Company are located.

The case of the citizens of Hiland avenue against the Hiland Avenue Electric Company came up before Judge White a few days ago. The plaintiffs brought the suit to prevent the construction of the line on Hiland avenue, because they claim it will spoil their property. The judge at once granted a preliminary injunction pending the hearing of the case.

The suit of the Pittsburgh Traction Company against the Duquesne Traction Company came up last Wednesday for a hearing before Judge Paxon in the Supreme Court of Pennsylvania at Harrisburg. The case originated from the fact that the Pittsburgh Traction Company claimed the right of way on certain streets upon which the defendant corporation is now laying tracks for an electric road. The judge dismissed the case and ordered the costs to be paid by the plaintiff company.

The directors of the Westinghouse Electric Company held a special meeting in the Westinghouse building, this city, June 4th, and passed the following resolutions:

Resolved—That a meeting of the stockholders of this company be called to be held at the office of the company, Westinghouse building, Pittsburgh, Pa., on July 8, 1890, at 2 o'clock, p. m., for the purpose of taking such action as shall be necessary to transfer the business of the Westinghouse Electric Company to the Westinghouse Electric and Manufacturing Company, and to transact such other business as may be brought before the meeting.

Resolved—That a meeting of the stockholders of this company be called to be held at the office of the company in the Westinghouse building, Pittsburgh, Pa., on July 8, 1890, at 2 o'clock, for the purpose of holding an election for or against the increase of the capital stock of the company; that notice hereof be published by the secretary as required by law, and that the transfer books be closed from July 1 to July 8, 1890, both inclusive.

It was also learned at this meeting that all of the regular stock of the Westinghouse Electric Company has been transferred to the Westinghouse Electric and Manufacturing Company, so that at the time of the meeting a formal action may be assented to and the business thereafter conducted by the Westinghouse Electric and Manufacturing Company. The aggregate sales of the Westinghouse Electric Company and its leased companies amounted to $4,362,000 in the year 1889, and for the first three months of this year, in the lighting business alone, the increase over the same period of last year was about 80 per cent. Beginning with the month of May the company has taken orders for the supply of railway equipment and contracts have already been closed during the one month for upward of $200,000 of material, with negotiations well advanced for more than four times that amount, indicating that for the year 1890 the sales of the company will be greatly in excess of last year.

PITTSBURGH, PA., June 6, 1890.

SAN FRANCISCO.

Personal Items--Electric Railway Work—Laying the Honolulu Cable.

J. B. GILL has disposed of his interests in the San Francisco district system, and with his improved "call box" has established himself in Cleveland, O., where he has contracted to do the entire Western Union delivery in conjunction with other district business.

Since the death of Geo. S. Ladd, his successor, John I. Sabin, is not allowing grass to grow under his feet. He is in everything in which a dollar can be turned with interest. His last is the Auxiliary Fire Alarm and the Municipal Police Telegraph.

James Gamble is still in the electric field, and is as positive and as energetic as when he pioneered the first wire over the Sierra Nevada mountains. He is building an electric railway from Oakland to Berkeley, which will be on the overhead wire system. Mr. Gamble would have nothing to do with any other system than the overhead, which he claims is the only one for this climate. It will command a fine view of San Francisco Bay and the Golden Gate, as well as being a boon to suburban residents. He expects to have it in operation by July 1st.

James Power, who was telegraph operator with General Roberts in Afghanistan, and who drew lots with a half-caste to accompany the ill-fated though brave Captain Louis Cavignari to Cabul, is now engaged laying cables connecting the Hawaiian group, with headquarters in Honolulu.

San Francisco, Cal., June 1, 1890.

REPORTS OF COMPANIES.

THE CONSOLIDATED ELECTRIC STORAGE COMPANY.

This company has just been organized for the purpose of manufacturing and selling storage batteries solely, with Mr. Wm. Bracken as president. The company owns the Julien storage battery patents—more especially that for the inoxidizable support plate—and the exclusive right to use for the whole of the United States all the Brush storage battery patents and inventions. Principal among these are the Brush patents, Nos. 337,298 and 337,299, covering the mechanical application of any absorptive substance to a conducting support; and the Brush patent, 266,090, which covers a support plate or a conducting support with receptacles for the active material; in addition to these, also, the Brush patent No. 260,654, which covers the application of oxide of lead to the support plate by pressure. The new company also owns the mechanical filler patents of Morris and Salom, which cover the process and machine for filling the conducting support or grids with active matter. They are more especially capable of doing this when the active matter is applied in the form of a powder. The two first mentioned Brush patents run 13 years from May, 1889; the mechanical filler patents have about 16 years of life, and the Julien storage battery patent, No. 347,300, being for his inoxidizable support plate, has about 14 years to run.

The Julien Electric Traction Company has sold its cars and everything in relation to traction to the United Electric Traction Company, the latter company having bought not only all the traction interests of the Julien Electric Traction Company, but also all the Daft companies, including the Daft Electric Light Co., with its factory at Marion, N. J., the Daft Electric Power Co., with its three stations in New York, and the Daft Electric Power Co. of Newark, and the Daft Electric Power Co. of Philadelphia. The United Electric Traction Co. have also purchased the Chamberlain battery rack patent. The United Electric Traction Co. has acquired from the Julien Co's. such patents relating to the application of storage batteries to the propelling of street cars, as will enable that company to make storage battery traction a specialty, but according to Mr. Bracken, there is no understanding, oral or written, between The Consolidated Electric Storage Co. and The United Electric Traction Co. as to the sale of batteries to the Traction Co. or as to favoring them in any way over any others desiring batteries for traction.

It will be the policy of the Consolidated Electric Storage Co. to furnish batteries to everybody on equally favorable terms. As indicating the demand there is for storage batteries, Mr. Bracken states that their Camden factory sold last month 1,294 accumulators although they have not a single agent in the field soliciting orders.

THE UNITED EDISON M'F'G CO.

From information imparted to us by the United Edison M'f'g Co. it would appear that the electric light business in isolated plants and small central stations continues to grow in a very marked and satisfactory manner:—

The increase on the sale of dynamos by the "Cash Installations Division" of the United Edison M'f'g Co. during the month of April this year shows 204 per cent. more than for the corresponding month in 1889, together with a greater percentage of lamp capacity of the dynamos. The dynamos have been installed in all parts of the Union, from the Golden Gate City to small villages in Maine—from New Orleans, the Queen City of the Gulf of Mexico, to the newly settled districts in the far northwestern territories.

The lamp sales have also vastly increased; the percentage of increase for the month of April being 116 per cent. more than for the corresponding period last year, showing, it is claimed, that the policy of the Company in mounting Edison lamps with bases to fit the various sockets that are in use, thus enabling consumers operating plants other than Edison to secure the benefit due to the Edison lamp, has been a wise one.

The United Edison M'f'g Co. for the past eight months have been gradually getting their business in shape to attend to all construction themselves and to supply their plants with the various materials they need. All construction work for the Edison System throughout the United States and Canada, is now done by the Company under a very comprehensively organized construction force.

The company have also established a depot of supplies in Chicago, Denver, San Francisco and Canada, in addition to a New York depot, and now carry in each one of these localities a complete stock of dynamos, lamps, sockets, switches, cutouts, wire of various makes, in fact, all materials which are used in connection with electric light and power plants. This arrangement is proving extremely satisfactory to the purchasers and owners of Edison plants, as the Company are now enabled to install a plant upon short notice and are able to furnish any supplies required immediately, from stock at a short distance from the purchaser.

It has been accepted generally by the Electric Light Companies that the summer months show an unusual falling off both in regard to lamp sales and installations. But from the amount of business that is being done and the orders that are being placed, this Company will, it is believed, prove a notable exception to the rule this summer.

THE PULLMAN-WESTINGHOUSE "DEAL."

The principals in the arrangement between the Pullman and Westinghouse interests are very reticent as to the rumors now afloat, but the subject is a prominent topic in more than one city. A special despatch from Pittsburgh, of June 3, says:—"The stock of the Westinghouse Electric Company is to be increased $3,000,000, or from $5,000,000 to $8,000,000. Pullman, the car-builder, is to take the entire issue at par or $50 a share. The incentive with Mr. Pullman is the manufacture of cars for electric street railway lines. The Westinghouse Company will both build and equip the cars. Details of the deal are now being arranged."

A later despatch of June 5, from the same city, says:—"Sixteen miles up the Allegheny river, at Parnassus, 850 acres of land have just been secured as a site for extensive electric car works, to be erected jointly by the companies controlled by George W. Pullman and George Westinghouse, Jr. The details of the new enterprise have not been given out, but Mr. Pullman will look after the car works, and Mr. Westinghouse will control the electrical appliances. Announcement is also made that on July 8, the stockholders of the Westinghouse Electric Company will pass upon the proposition to transfer its business to the Westinghouse Electric and Manufacturing Company. It is also proposed to increase the stock from $5,000,000 to $8,000,000. President Westinghouse favors this plan, and in support of it quotes $4,362,000 as last year's business, and says that during May orders for $200,000 worth of railway equipments alone were taken, to say nothing of the other lines of business."

These reports have had their effect on the stock market. The New York Stock Exchange reports say as to Pullman stock:—"The advance to 20) was accomplished on light purchases, the stock being as usual put up sharply against bids. What may possibly have had something to do with the advance was the announcement that the Westinghouse and Pullman people were about to put up a large establishment near Pittsburgh, for the manufacture of electric cars, 300 acres of land having been purchased for the purpose."

THE MINNEAPOLIS EDISON EXHIBITION.

Mr. Luther Stieringer, the well known expert, who has been called upon by the management of the Minneapolis Exhibition to assist in the preparation of the electrical plans this year, returned to this city en route for the South, where he will enjoy a brief vacation. As is already known, the main feature of the Exhibition will be the Edison exhibit from Paris, recently displayed at the Lenox Lyceum. This, however, will be supplemented by some special novelties, and the "Tower of Light" effects will be repeated, though upon a scale that is far beyond anything yet attempted. We have had the pleasure of looking over the plans, and can only say that if they are carried out, even approximately, the effects at the Lenox will be cast into utter insignificance. Minneapolis is fortunate in having such an opportunity, and there is no doubt that the exhibition will interest and attract the whole Northwest.

DELAY IN THE KEMMLER CASE.

In the general term of the New York Supreme Court at Buffalo, on June 3, the decision of Judge Underwood, of Auburn, in the Kemmler habeas corpus case was affirmed. This allows the case to go at once to the Court of Appeals. The only question at issue is whether Kemmler can be legally executed by the warden of Auburn prison.

The Elgin, Ill., Electric Light and Power Co., have just incorporated, with $100,000 capital. This company will install immediately extensive Wood arc and Slattery induction systems of lighting, having closed contracts therefor with the Ft. Wayne Electric Company through the latter's Chicago office.

SOCIETY AND CLUB NOTES.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.

The ninth annual meeting of the Association of Railway Telegraph Superintendents will be held at the Cataract House, Niagara Falls, N. Y., on Wednesday, June 18. The support given to the Association by leading railroads, and the success with which it has been attended since its formation on Nov. 20, 1882, in elevating the standard of employees and eliminating those of objectionable records from the service, have been very gratifying, and the coming meeting is expected to be one of the most important yet held. Papers are to be read on various topics, signals, electric devices, etc. It is desired that as many railroads as possible be represented. Any officer in charge of operators is eligible on the payment of $3 membership fee, which includes all dues for the year. The officers of the Association are: C. A. Darlton (Richmond & Danville), President, Washington, D. C.; G. T. Williams (New York, Chicago & St. Louis), Vice-President, Cleveland, O.; P. W. Drew, Secretary, 535 Sixty-seventh street, Englewood, Ill.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The last meeting of the Institute for the current season 1889–90, will be held at 8 p. m. on June 17, at the house of the American Society of Civil Engineers, 127 East Twenty-third street, when two papers will be read, one by C. Humphrey and W. H. Powell on "The Efficiency of Transformers," and the other by Prof. H. J. Ryan, entitled, "Notes upon Some Experiments with Alternating Current Apparatus." These two papers sum up the latest work at Cornell University in this field, and will prove very valuable and interesting additions to the literature of the subject as well as to the Institute *Transactions*, now in such high and well deserved repute at home and abroad.

THE ELECTRIC CLUB OF NEW LONDON, CONN.

The Electric Club of New London, Conn., has been organized. The officers are Ernest W. Bruch, president; James R. Troland, treasurer, and Clarence W. Ford, secretary. The club starts out with a small membership, but expects to grow and be useful in its district.

LEGAL NOTES.

DOUBLE CARBON ARC LAMPS.—BRUSH ELECTRIC CO. *vs.* SPERRY ELECTRIC LIGHT CO.

In the suit of the Brush Electric Co. against the Sperry Electric Light Co. for infringement of Brush's patent, No. 219,208, for double carbon arc lamp, an injunction was granted Monday, June 2, by Judge Gresham against the defendants, to go into effect in thirty days. This result will be noted with great interest by manufacturers of arc lighting apparatus generally.

PATENT NOTES.

A BILL TO INVALIDATE UNUSED PATENTS.

A special despatch from Washington, D. C., calls attention to the Simonds patent bill now before the House of Representatives. The fifteenth section of this measure, as reported from committee, provides that within five years from the date of issue of each patent "some person interested in or under the same" shall pay a tax of $10 upon the same to the Commissioner of Patents, or in default of such payment the patent shall expire; and within another five years an additional tax of $25 must be paid in like manner to keep the patent alive still longer.

The theory upon which this proposed change in the law proceeds is that the protection of the government is now extended to a great mass of inventions which are not only of no use to their inventors or to the world, but which are actually an obstruction to the free action of the national genius. While they remain alive no inventor dares invade their especial field for fear of involving himself in expensive litigation. Thus, not only is an injustice done to men who might meanwhile be making headway with really valuable devices of their own, but the public suffer a wrong in being deprived of the use of improvements which they might just as well be enjoying. In the great majority of cases the worth of an invention, if it has any, is discovered in a few years, for it is during that time that the inventor himself is most enthusiastic and active in bringing it to the notice of capitalists and trying to put it upon the market. While the chances of success seem fair he places a high estimate on the value of his device. After it passes a certain point, however, he is apt to become somewhat discouraged, and then it is proposed to offer him the alternative between proving his faith by the payment of $10, and letting his patent rights expire. It is the common rule with devices which have an outward look of excellence, but little practical value, that, having exhausted his resources in striving to interest capitalists, the inventor sells out for a trifle to some speculative concern; a stock company or "syndicate" is then organized by the aid of generous advertising, and the innocent investors, who usually know nothing about patents or patent law, never see a penny of their money again in the form of either principal or interest. It is believed by the friends of this bill that these speculative sales will be less frequent when the purchaser either has to pay a tax at the outset in order to keep his patent alive, or knows that at the end of the next five years he must pay a still larger tax or let the whole thing go.

Of the three points urged against the bill by patent lawyers, the first is that it would tend to discourage invention by adding to the burdens of the patentee; but to this the response is that the present cost of a patent is no deterrent, while the indications are that the fees might be doubled without materially lessening the number of applications. The second complaint is that the terms of the bill are too indefinite. If "some person interested" is required to pay the tax, there is always danger of its lapsing through inattention or accident; but to this it is answered that the Commissioner of Patents will be called upon to formulate a system by which the whole business can be conducted without injustice to any one. The third fault found with the taxing programme is that it is needlessly complicated. There seems to be some just ground for this criticism. If, instead of two payments at various times, a single payment were required—say $25—at the end of the seventh or eighth year, it would answer the same final purpose, and meet the more cordial approval of experts who dislike to see our patent system loaded down with technicalities any further than is required for the protection of inventors and the public. Finally there is a plea that the plan is borrowed from the English system.

INVENTORS' RECORD.

Patents issued June 3, 1890.

Alarms and Signals:—*Indicator for Elevators*, J. P. Cushing, 429,189. *Electric Fire-Alarm and Extinguishing Apparatus*, C. E. Ongley, 429,318. *Electric Call and Voting Apparatus*, T. M. Wilkins, 429,330. *Watchman's Time Recorder*, J. F. McLaughlin, 429,360.

Clocks:—*Electrical Clock-Winding Mechanism*, A. Ward, 429,396.

Conductors, Conduits and Insulators:—*Cover for Electric Subways*, J. Stafford, 429,251. *Machine for Stripping the Lead Covering from Conductors*, D. Thatcher, 429.292. *Electric Conductor*, H. B. Cobb, 429,304 and 429,305. *Joint for Electric Conductors*, H. B. Cobb, 429,306. *Underground Conduit for Electric Wires*, H. B. Cobb, 429,307. *Apparatus for Covering Wire with Plastic Material*, D. D. Parmalee, 429,581.

Distribution:—*Process of Maintaining a Uniform Current in Electric Circuits*, J. M. Bradford, 429,333. *Electrical Converter*, G. Pfannkuche, 429,583.

Dynamos and Motors:—*Apparatus for Rectifying Electric Currents*, F. Anderson, 429,109. *Field-Magnet for Dynamos*, E. Wagemann, 429,490.

Lamps and Appurtenances:—*Portable Electric Lamp*, J. H. Irwin, 429,172. *Manufacture of Carbon Filaments*, A. de Khotinsky, 429,534 and 429,535. *Electric Arc Lamp*, C. F. Keller, 429,573.

Medical and Surgical:—*Medical Battery*, F. P. and W. A. Hoeneman, 429,447.

Miscellaneous:—*Apparatus for Detecting Leaks in Pipes*, W. W. Rosenfeld, 429,286. *Electric Heating Apparatus*, C. E. Carpenter, 429.559 and 429,560. *Method of Electric Heating*, C. E. Carpenter, 429,562.

Metal Working:—*Electric Soldering Iron*, C. E. Carpenter, 429,561.

Railways and Appliances:—*Electro-Magnetic Locomotive*, R. N. Allen, 429,107. *Trolley-Carrier*, B. F. Brown, 429,113. *Electric Railway System*, W. D. MacQuesten, 429,199. *Electric Tramway and Car*, A. L. Lineff, 429,277. *Continuously Operated Electric Motor*, W. D. MacQuesten, 429,314. *Electric Railway Motor*, F. J. Sprague, 429,327. *Trolley for Electric Railways*, W. S. Blauvelt, 429,413. *Interlocking Electric Railway System*, J. Ramsey, Jr., and F. C. Weir, 429,478. *Electric Railway Signaling Apparatus*, C. H. Rudd, 429,483. *Electric Railway Signal*, H. A. Parmalee, 429,582.

Secondary Batteries:—*Electrode for Secondary Batteries*, C. Hering, 429,272 and 429,274. *Secondary Battery*, C. Hering, 429,273.

Telegraphs:—*Printing Telegraph*, J. Burry, 429,115. *Multiple Telegraphy*, E. N. Dickerson, Jr., 429,233. *Telegraphy*, S. M. English, 426,377. *Printing Telegraph*, A. T. McCoy, 429,576 and 429,577.

Telephones and Apparatus:—*Magneto-Telephone*, N. B. Ginochio, 429,129.

THOMAS, SHEPARD & SEARING.

We take pleasure in noting an advance in engineering interests in the West by the recent establishment of Thomas, Shepard & Searing, of Denver, Col., who are making a specialty of a higher class of work than has hitherto been attempted in that part of the country. We quote the following from their circular :

"Besides acting as expert and consulting engineers, giving advice and testimony on mechanical and electrical problems, we will give special attention to the following classes of work : Tests of engines, boilers, machinery and electrical apparatus. Experiments and researches on material and processes. Development of inventions and design of special machinery. The accurate determination, by means of the Emerson power scale, of the power required to drive machinery."

Messrs. Thomas and Shepard are graduates of the Mass. Institute of Technology, and Mr. Searing is a graduate of Stevens Institute of Technology. All the members of this firm are young men and all have had considerable experience in experimental research either under great scientists or in large manufacturing establishments, and we feel confident that the courage which backed them in making this venture will carry them through to success.

THE BAKER COMMON-SENSE OIL FILTER

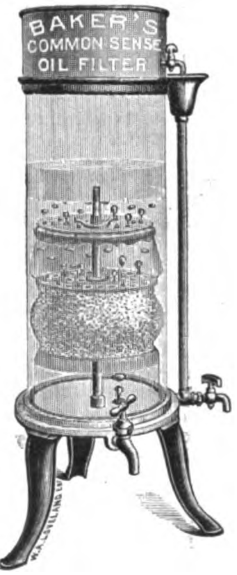
With the dawn of the high-speed engine, the dynamo and motor, there came demands for a more plentiful and constant supply of lubricating oil, of a somewhat lighter and more even quality than had before been generally used. The high cost of the oil soon led to catching it and using it over a second time. This same created the necessity of a proper oil filter to work perfectly, as oil seems "sticky" in relation to dirt.

Some four years ago, Mr. C. F. Baker, chief engineer for C. A. Pillsbury & Co., of Minneapolis, produced, as a result of several years' experimenting, a filter that seemed to be perfect for the purpose. The assistance of Mr. W. E. Crane was obtained, and it was put into shape to manufacture on a large scale.

It has now been so long in extensive use, and particularly in electric light plants, that it is fast becoming a familiar and necessary adjunct for establishments of this kind.

In the "Common-Sense" oil filter, as it is called, the filtering material is entirely submerged in water, and is enclosed in the upper part of two bell-shaped glasses, as shown in the accompanying illustration. The oil is fed from the tank on top down through the side pipe, thus entering the filter at the bottom, near the centre. Its lesser specific gravity causes it to rise through the water, and accumulate beneath the filtering material, being enclosed by the glass bell.

By capillary attraction and its gentle pressure upward from its lightness, the oil gradually goes up through the filtering material in the lower glass bell and is caught and required to pass through the upper one containing a different filtering medium, in the same manner. The clean oil accumulates on top of the water, and is drawn off at the front faucet, which communicates with the central pipe. The water is drawn off at the side faucet.



BAKER COMMON SENSE OIL FILTER.

A short consideration of the construction of this filter makes it very evident that it is constructed on scientific and common-sense principles. The gravity of the oil is reversed and diminished to less than one-tenth by the presence of the water. The gravities of the metallic and all other impurities, have the gravity of the water subtracted from theirs, leaving them with only a slight inclination to drop, while the gentle but sure tendency of the oil to rise while passing through the filtering medium effects a most natural and perfect separation, which does not soon clog up the filtering material, and bottle samples fail entirely to show any settlings in the filtered oil.

The filters have been highly endorsed by well-known electricians and engineers, and are claimed to pay for themselves in a very few weeks, admitting of the oil being used over as many as forty times in some cases. A great benefit arises from the fact that the machinery may be amply oiled without stint. They are made of a very tough quality of glass, and the whole operation is visible. The construction is such that they may be taken apart entirely by simply unscrewing two thumb-nuts.

The filter, which occupies but little space, and is an ornament to the dynamo or engine room, is manufactured only by Walter E. Crane, of Minneapolis, Minn.

NOISELESS SOLID RAW-HIDE GEARS.

In many situations it is necessary to employ gear wheels running at a high rate of speed, and the wear which takes place under those conditions, together with the accompanying noise, makes their use objectionable. Many attempts have been made to overcome these defects but probably the most successful has been the substitution of some fibrous, non-resonant material instead of the metal gears heretofore employed. Of these materials the patented solid raw-hide gears made by the New Process Raw-hide Co., of Syracuse, N. Y., have met with remarkable success.

In the manufacture of the raw-hide, great pressure is applied, and all superfluous matter eliminated, leaving the same extremely light and making it the strongest material for its weight known.

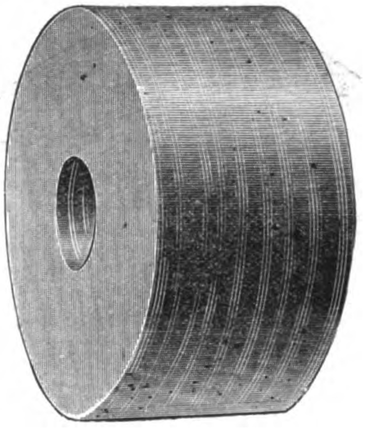


FIG. 1.

The accompanying engraving, Fig. 1, shows the blanks as manufactured for spur and bevel gears, and Fig. 2 shows the finished gear. These gears, as is well known, have come into extensive use on electric cars, where their silent and even operation has added much to the comfort afforded by these cars. These gears may be run together or against metal gears, and require no lubrication. These raw-hide gears have been in operation for some time. Thus, on the East Harrisburg Passenger Railway some of the raw-hide gears made by the New Process Raw-Hide Co., have run 18,000 miles without a single mishap.

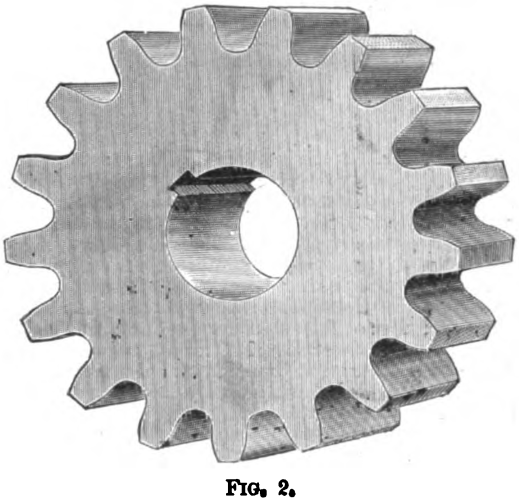

FIG. 2.

In addition to their use on electric cars, these gears are well adapted for other machinery, such as machine tools, etc., and several well-known tool builders such as Pratt & Whitney, of Hartford, use them in their work. These gears are not only remarkably durable in themselves, but it is claimed that the life of large iron gears is longer, used in connection with them, than when meshing with metal pinions.

THE BRISTOL RECORDING PRESSURE GAUGE.

The remark has often been made that the management of the coal pile determines whether money is made or lost in the operation of an electric light station. The coal being the original source of power, it is evident that anything to increase economy and to regulate its consumption must lead to a direct benefit to the management, and this is being recognized more and more by the introduction of coal saving devices. Given these, together with efficient engines, the results must prove satisfactory. But even with the best appliances, neglect on some points which require the exercise of intelligence may not develop the full value of the economizing apparatus, and among these the bad management of the boilers is a frequent source of loss. Careless and wasteful firing, accompanied by successive rise and fall of pressure, may vitiate all the benefits which would be otherwise derived, and hence a check upon the work of the fireman will tend to make complete the economy generally aimed at. For this purpose a recording steam gauge is now acknowledged to be an essential part of the equipment of the boiler room of an electric light station, so that a continuous record of the work of the firemen may be constantly before the eyes of the manager. At the recent meeting of the American Society of Mechanical Engineers, Prof. W. H. Bristol, of the Stevens Institute of Technology, described a very ingenious and simple recording pressure gauge which elicited the warm admiration of many present. The accompanying engraving, Fig. 1, shows the instrument complete, and Fig. 2 shows the pressure tube with the inking pointer attached, the front of the case, dial and cover of the clock being removed. As will be seen, the pressure tube, A, is of flattened cross-section and bent into approximately a sinusoidal form. A flexible strip, B, of the same metal as the tube is secured at the ends and along the bends. The bent tube may be considered as a series of Bourdon springs placed end to end. It is evident that pressure applied to the tube produces a tendency to straighten each bend, or collectively, to elongate the whole. This tendency to lengthen the tube is resisted by the flexible strip B, and is thereby converted into a multiplied lateral motion. The inking pointer is attached directly to the end of the pressure tube, as shown in Fig. 2, from which it will be seen that the usual mechanism and multiplying devices are dispensed with, since the motion of the tube itself is positive and of sufficient range. The special advantage of this is evident, considering that in the usual forms of pressure gauges the movement of the tube or diaphragm is small, and requires a somewhat complicated system of mechanism to multiply the motion many times before it is available for indicating purposes.

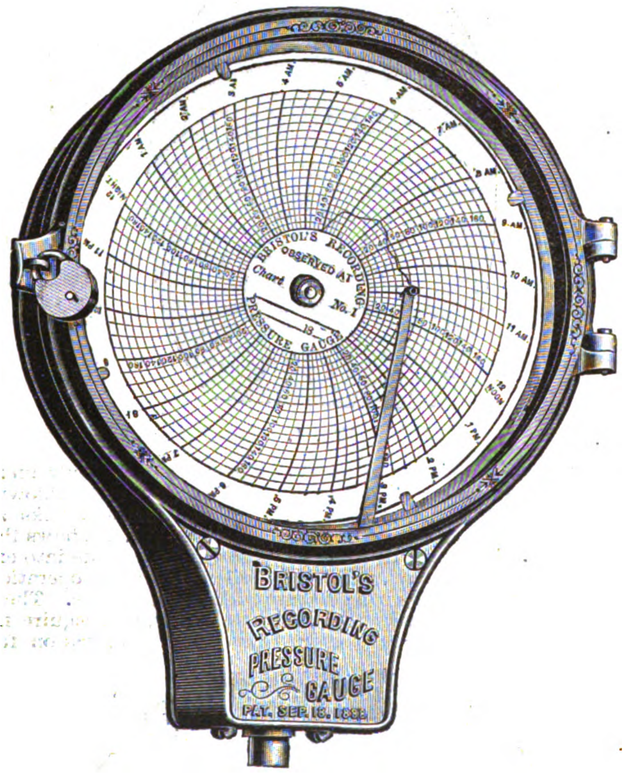

FIG. 1.

In the instrument illustrated the tube is designed for a range of 180 pounds per square inch; for other ranges its sensitiveness may be varied at will by changing its proportions, as length, shape of cross-section, or thickness. The printed charts for receiving the record make one revolution in twenty-four hours, and are provided with radial arcs and concentric circles, the divisions on the radial arcs corresponding to differences in pressure; while those on the concentric circles correspond to the hours of the day and night.

During the past year and a half several of the instruments have been in operation upon the steam boilers at the Stevens Institute and have given perfectly satisfactory results, and others are now in operation in a number of electric light stations. It is evident that the instrument is adapted for a vacuum as well as for a pressure gauge.

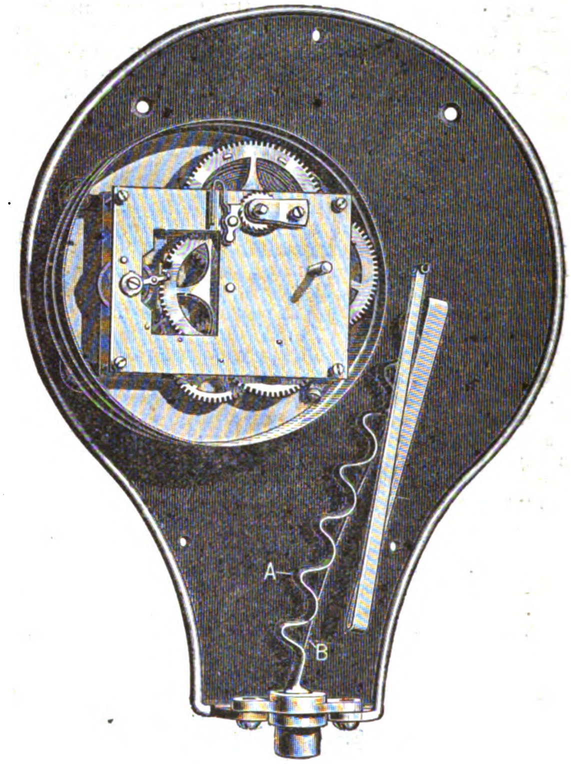

FIG. 2.

In the discussion which followed the description of Prof. Bristol's recording gauge, Mr. Chas. A. Hague pointed out that cases occur where boilers are left with banked fires during periods when not in use, but where it is desired to keep them in readiness to be used at short notice, or where it is desired for any reason to maintain a moderate steam pressure during the period of inactivity. When such boilers are left alone nobody really knows to what point the pressure at times has risen, and thus seemingly inexplicable accidents happen. The pressure is carried through the days perhaps at 80 pounds, and it is supposed to be run down and be kept say at 25 pounds all night. The fires are banked and the boilers are left to themselves, apparently in a safe condition. But with boilers set in brickwork the fire-brick lining of the setting gets pretty hot during the day, and forms, as it were, a reservoir of heat; and if the fireman is in a special hurry to get away, it very often happens that sufficient precaution has not been taken to prevent the rise of steam pressure during the night. Now, without a recording pressure gauge of some kind nobody could tell in the morning to what point pressure might have risen during the night, although in the morning it might be even lower than the regulation limit for the night time. With a record made by a gauge during the night, locked up in the superintendent's or the manager's office, and out of reach of the fireman, the unexpected and perhaps dangerous pressure to which a boiler might be subjected can be known and precautions taken accordingly. Mr. A. R. Wolff also called attention to the fact that the gauge was simple, could be easily constructed, and, consequently, placed upon the market at a moderate price—one which would make it possible for engineers to include a recording gauge in their specifications.

The instrument described above is manufactured by the Bristols' Manufacturing Company, of this city and Waterbury, Conn.

TRADE NOTES AND NOVELTIES.

AND MECHANICAL DEPARTMENT.

THE E. P. GLEASON MFG. CO.'S APPLIANCES.

For some few years past it has been the habit of the E. P. Gleason Mfg. Co., of 181-189 Mercer street, this city, to issue a catalogue of its electrical appliances. Last week it brought out the edition for 1890 in a manner evincing not only liberality and enterprise, but giving new evidence, if it were necessary, of the intention of the concern to repeat and excel in the electrical field the successes and triumphs that have distinguished it in the past, and through long years in the domain of gas lighting. This catalogue is a sumptuous large folio of 73 pages, bound in stiff stamped cover. One does not greatly envy the experts who had to prepare such a publication for press. It contains no fewer than 900 cuts, and of these over 400 are new, or have not before appeared in the catalogue. The title page gives views of the company's fine headquarters and warerooms in this city, and of its glass works in Brooklyn. The index counts up no fewer than 74 distinct headings, many of which have several subdivisions, and it is suggestive of the various improvements and evolutions that have been necessary to render the electric light safe and convenient. In fact, a very large part of the success of the electric light lies in the perfection of these details, including, for example, such things as lamp guards, insulating joints, sockets, shades, holders, switches, moldings, rosettes, brackets, etc.

Among the features that may be specially mentioned is the grouping of the gas and electric glassware for combination fixtures, so as to show exactly how such fixtures look when the globes for both kinds of light are placed on them. The globes shown are of very graceful and elegant pattern. We note also some new glassware called the "Stalactite," shown in bulbs and radiators, the shape been modeled after that of the stalactites that form slowly in the cavernous recesses of the earth. These stalactite globes are made up in rich cut, etched, crystal, flint, twist and spot opalescent glass, and bid fair to become extremely popular, having created a very favorable impression wherever seen. Another line of novelties we notice is that of suspended opal glass reflectors, with prisms. In the line of circuit details, we note some useful and ingenious new adjustable double-pole cut-outs, so made that the fuses are carried in the removable porcelain caps or covers. The pages devoted to insulating joints also show several excellent novelties.

Taken as a whole, the catalogue is the best publication of the kind we have seen for a long time past, and is one that should be in the hands of all intending purchasers of electrical appliances for arc and incandescent lighting or other electrical work.

LARGE CROWDS SUCCESSFULLY CARRIED IN CLEVELAND AND BUFFALO.

Decoration week clearly demonstrated the ability of the electric system of street car propulsion to take care of enormous loads. In the cities the amount of travel imposed upon the electric cars was far in excess of that for which they were intended, but in spite of the extraordinary crowds carried in each case, the operation of the cars was successful in every particular.

At Cleveland on May 30, occurred the ceremonies connected with the dedication of the Garfield Memorial, and the city was crowded with strangers, all of whom of course took the electric cars to the Park. The greater part of these people were carried by the Sprague electric cars on the East Cleveland Street Railway, though many passed over the line of the other two street railways in Cleveland. The cars on all three lines were crowded with passengers. Many of the cars ran trailers, and both motor car and trailer were taxed to their uttermost capacity.

In Buffalo, on the following Sunday, the four electric cars in operation on the Buffalo Street Railway ran all day long, drawing one or two trailers each, and they are credited with carrying in all over 15,000 passengers.

It is said and can readily be believed that the managers of the roads in both of these cities are very enthusiastic over the operation of the cars, and the press of the city has spoken in the highest terms of the performance under these most trying conditions.

CLEVERLY'S BLOTTING PADS.

H. A. CLEVERLY, of 1018 Chestnut street, Philadelphia, has made a new departure, and in addition to Perret motors, bells and annunciators, general electrical supplies, etc., is now handling blotting pads in large quantities. He is disposing of several car loads daily. He will no doubt find this branch of business enlarge, as they go for absolutely nothing. The quality of the pads is excellent, and they absorb ink as readily almost as Mr. Cleverly does business orders.

LIGHTING THE HOTEL ABERDEEN, NEW YORK.

An exhibition was given at the Hotel Aberdeen, on May 26, of Mr. J. H. Mason's primary battery work in electric lighting, fan propelling, etc. The plant consisted of one 25 c. p. lamp, three 6 c. p. lamps, and a fan driven by an ⅛ h. p. motor. Everyone was greatly pleased with the exhibit, and several orders for both fan and lights were the result. A large number of ladies and gentlemen were present, including Mr. A. Foster, the proprietor of the hotel.

THE TENNESSEE VOLTA ECLIPSE ELECTRIC COMPANY.

This company has been formed at Memphis, Tenn., to introduce the "Volta Eclipse" primary battery, invented by Mr. W. A. Crowdus, who is well known in the battery field. Connected with this company is the Volta Electrical Manufacturing and Supply Co. It is claimed that with this battery light and power can be furnished as cheaply as by dynamo. Mr. Crowdus says: "Recognizing the public's general opinion of primary batteries I have only to say that we make few claims but do much work." Of the first named company J. W. Allison is president; B. M. Stratton, vice-president; D. T. Porter, treasurer; T. S. Carman, manager; and W. A. Crowdus, electrical engineer. The company is beginning its work in Tennessee and adjoining States.

WOODHOUSE & RAWSON'S UNITED LIMITED EXHIBIT AT EDINBURGH.

Messrs. Woodhouse & Rawson United Limited have designed and carried out one of the prettiest lighting exhibits in the Electrical Exhibition now being held at Edinburgh, Scotland. It certainly presents at night a very attractive centre to the ornamental grounds of this exhibition. The band stand in question has been specially designed by Mr. Carter, the architect and engineer of the Exhibition. It is lit in rather a unique manner. In the centre of the sounding board is placed a Trotter diffuser with three lamps, and from this there are radial lines of 8 c. p. lamps, frosted in colored shades. Around the edge of the band stand are rows of small lamps and shades, while over the steps are placed in cut glass fittings two high c. p. lamps. Outside the stand on top are eight 100 c. p. incandescent lamps hanging from brackets and enclosed in cut glass fittings; lower down still are eight spikes, which are illuminated at their points by smaller lamps. The current is supplied from the central machinery hall by means of a pair of underground lead covered mains. The dynamo is of the Elwell Parker type, compound wound, 102 volts, and is driven off one of the large horizontal Robey engines. This machine also supplies the stall of Messrs. Woodhouse & Rawson, on which are shown Scott's electric flash signaling lantern for signaling by flashes according to the Morse alphabet; Barber Starkey's accumulator cut-out; Horn's electric tachometer; insulating material for switch bases; voltmeters, ammeters, lamps, telegraph instruments, bells, etc.

ADVANCE IN RUBBER GOODS.

A meeting of the Manufacturers of Mechanical Rubber Goods was held in this city May 27. The following manufacturers were represented and participated in the action taken:

New York Belting and Packing Company, New York; Boston Belting Company, Boston, Mass.; Gutta Percha and Rubber Mfg. Company, New York; New York Rubber Company, New York; Revere Rubber Company, Trenton, N. J.; Boston Woven Hose Company, Boston, Mass.; Brook, Oliphant & Co., New York; Trenton Rubber Company, Trenton, N. J.; New Jersey Car Spring and Rubber Company, Jersey City, N. J.; Hamilton Rubber Company, Trenton, N. J.; Home Rubber Company, Trenton, N. J.; B. F. Goodrich Company, New York; Whitehead Bros. Company, Trenton, N. J.; Star Rubber Company, Trenton, N. J., Erie Rubber Company, Erie; Pa.; Hartford Rubber Works Company, Hartford, Conn.; National India Rubber Company, Cleveland, Ohio; Mercer Rubber Company, Trenton, N. J.; Cleveland Rubber Company, Cleveland, Ohio; Chicago Rubber Company, Chicago, Ill.

In view of the advance in crude rubber it was unanimously decided to advance prices on rubber hose, belting and packing 10 per cent., such advance to go into effect June 2. This advance is regarded as conservative and justifiable and the market is characterized by firmness and strength.

THE BRUSH AND SHORT SYSTEMS.

The Brush Electric Company and the Short Electric Railway Co. of Cleveland, have put in the hands of their traveling agents and representatives an extremely neat and effective business card. On one side is a view of the magnificent Brush works at Cleveland, and on the other is a cut of the Short electric car, in full operation, on the overhead system. Both engravings, though small, are very clear and pretty, and the card cannot fail to make a most favorable impression on any one seeing or receiving it.

THE EDISON UNITED MANUFACTURING COMPANY.

There has never been a superabundance of Edison lighting literature. On the contrary, we have often thought that the Edison Company suffered from its lack in this respect, since in these days it hardly pays any electrical concern to "hide its light under a bushel." We are glad to see that the want is now being supplied by the United Edison Manufacturing Company, which has just issued a very handsome pamphlet, for a copy of which we are indebted to the energetic general manager, Mr. H. Ward Leonard. The pamphlet is an oblong folio of 71 pages, the covers of cream white flexible card. The front cover is richly embossed in gold with the name of the company and with a large cut of the standard Edison dynamo. The back cover is not embossed but is printed in blue, gray and gold, with a full size Edison lamp and socket. The whole is tied together with lavender silk cord.

As a frontispiece, appears a fine view of the Edison Machine Works at Schenectady.

This is followed by an excellent brief description of the Edison system, a list of the details of a plant, an engraving of the Edison machine, and a table showing the sizes, speeds, weights, voltage and amperage of the different types, from 5 lamps up to 2,500 lamps capacity. A short description is given of the machine itself, and this is followed up by an illustrated description of the meters, lamps, sockets, switches, etc. This section is followed by one in which are comprised a larger number of replies to a series of questions addressed to purchasers and users of the Edison system, whether in central stations or isolated plants. It is a really magnificent exhibit for a company to make, and embodies not a little interesting and suggestive information. Succeeding this part, come the "standard specifications for electrical plants," and last of all is given a synopsis of the patent and legal points on which the Edison system bases its claims to the practical control of incandescent lighting in this country.

UTICA, N. Y., ELECTRIC RAILWAY.

The work on the electrical equipment of the Utica & Mohawk Electric Railway at Utica, N. Y., is being carried forward as rapidly as possible, and it will not be long before the cars will be ready for operation. The motors and line equipment have already been shipped, and the final shipment of station equipment is expected to be made in a few days. Each car will be equipped with two 15 h. p. Sprague improved electric motors with all the latest improvements and devices used upon any of the Sprague roads.

SAWYER-MAN LAMP FACTORY.

The large factory of the Sawyer-Man Co. at 510-534 West Twenty-third street, has again been undergoing enlargement, and in spite of the fact that the summer months are generally supposed to be those when light becomes a secondary consideration, the factory, Mr. P. H. Alexander says, will not be able to keep pace with its orders and the new business until the extensions and improvements are all available. The buildings when fully equipped will have a capacity of 15,000 lamps a day.

EXTENSION OF WESTINGHOUSE PLANTS.

The town of Oregon in the State of Illinois is determined not to be behind its sister towns in the matter of illumination. A company has recently been formed in Oregon, to go into the electric lighting business and the new corporation has placed an order with the Westinghouse Electric Company, for one of that company's 500 light alternate current incandescent dynamos. No time will be lost in the construction of the plant.

Moundsville, W. Va., will have an electric light plant. The Westinghouse Electric Company is about to ship to Moundsville, one of its five hundred light alternate current incandescent dynamos to fill a recently received order from a new lighting company there.

The Apollo Iron and Steel Company of Apollo, Pa., has decided to illuminate its works by electricity. The company has been prompted to make this improvement on account of the great increase in its business, which necessitates working at night. The new arc lighting system of the Westinghouse Electric Company, will be used in lighting the plant.

THE RICE AUTOMATIC ENGINE.

The John T. Noye Mfg. Co., of Buffalo, N. Y., have recently issued some new literature illustrative and descriptive of their well-known Rice Automatic Engine, which is now in extensive use in the electric lighting field. It is a "self-contained side crank" engine, and in this form is to be found in a great many stations. Of late the call has also been heard for compound, and compound condensing engines, and these the company is now supplying in the larger sizes. One of the pamphlets contains details of the various types; another gives a striking array of testimonials from users, dating down to the beginning of the present year.

THE NATIONAL ELECTRIC DEVELOPMENT COMPANY.

A company called the National Electric Development Company has been organized in San Francisco, to act as a branch of the National Electric Manufacturing Co., of Eau Claire, Wis. The last named company is fortunate in being under the management of Mr. G. B. Shaw, ex-mayor of Eau Claire, through whose direction and energy it is now doing a rushing business with its lighting and power apparatus. One of the staff of THE ELECTRICAL ENGINEER had the pleasure recently of visiting its factory, and was surprised at the great activity and the abounding signs of prosperity under a vigilant and capable management.

THE ST. LOUIS ELECTRICAL EXHIBITION.

MR. F. H. WHIPPLE is now in this city, having taken possession of his new offices in the Temple Court building, Beekman street. He is devoting his energies just now to work on the second annual electrical exhibition at St. Louis, which will last from September 3 to October 18. He is already in receipt of a large number of applications, and spaces will be alloted August 1. No charge whatever is made for space or power, and this fact coupled with the advantages of St. Louis as a distributing centre, will doubtless induce electrical concerns all over the country to make a large and creditable display. A great many novelties are expected.

PAGET & KINTNER.

The firm of Paget & Kintner, chemical and electrical experts and electrical engineers, of 45 Broadway, has been dissolved. Mr. C. J. Kintner will continue the business as successor at the old address.

WESTERN WORK OF THE THOMSON-HOUSTON COMPANY.

The Thomson-Houston Electric Co., through its general agent, Mr. Theo. P. Bailey, at Chicago, reports the following new business during the past month in the railway department: Missouri Railroad Co., St. Louis, Mo., 36 motor cars; Mound City Railroad Co., St. Louis, Mo., 25 motor cars; the Wichita Electric Railway Co., Wichita, Kan., 20 motor cars; Rockford City Railway Co., Rockford, Ill., 3 motor cars (increase); Jacob Rich, San Jose, Cal., 5 motor cars.

The Union Depot Street Railroad Co., St. Louis, Mo., equipped with 30 Thomson-Houston motor cars, was formally opened for business over the entire length of the road, extending from the heart of the city seven miles out in suburban territory, and we are informed the opening was a grand success.

The list of sales of Chicago office of the Thomson-Houston Electric Co. for the month of May is as follows:

Arc.—New Omaha Thomson-Houston E. Co., Omaha, Neb., 50 lights; Cheboygan, Mich., Lumber Co., 9 lights; Battle Creek, Mich., El. Light Co., 35 lights; Jas. P. Anderson, Trenton, Mo., 30 lights; Joliet, Ill., Wheel Co., 3 lights; Armour & Co., Chicago, Ill., 105 lights; Kalamazoo, Mich., Elec. Co., 50 lights; California Theatre and Hotel Building, San Francisco, Cal., 20 lights; Hammond, Ind., Milling Co., 50 lights; Salt Lake Power, Lt. and Htg. Co., Salt Lake City, Utah, 30 lights; Decatur, Ill., Gas Lt. and Coke Co., 50 lights; Edison Light Co., Grand Rapids, Mich., 50 lights; Denver, Col., Elec. Illuminating Co., 70 lights; So. Western Elec. Lt. and Water Pr. Co., Joplin, Mo., 100 lights.

Direct Incandescent.—G. F. & E. A. Burkhart, Chicago, Ill., 85 lights; Chas. Hebard & Son, Pequaming, Mich., 150 lights; Gratwick, Smith & Fryer Lumber Co., Oscoda, Mich., 350 lights; Excelsior Elec. Co., Port Huron, Mich., 20 lights; Osage Coal and Mining Co., McAlester, Ind. Ter., 300 lights.

Alternating Incandescent.—Central El. Lt. and Pr. Co., Sedalia, Mo., 650 lights; Jas. P. Anderson, Trenton, Mo., 650 lights; Moffett, Hodgkins & Clark, LaGrange, Ill., 650 lights; Kalamazoo, Mich., Elec. Co., 650 lights; H. M. Loud & Sons, Oscoda, Mich., 300 lights; Redding, Cal., Water Co., 650 lights; Highland Park, Ill., El. Lt. Co., 650 lights.

Motors.—S. E. Hopewell, Omaha, Neb., 2; A. H. Revell & Co., Chicago, Ill., 1; Western Thorn Type Setting Co., Chicago, Ill., 1.

BLISS & ANGELL.

Mr. Geo. H. Bliss, electrical expert, 225 Dearborn street, Chicago, has now associated with him as partner Mr. Jos. Angell (his former partner, Dr. Louis Bell having severed his connection) under the firm name of Bliss & Angell. Both gentlemen are to be congratulated upon this new connection. Mr. Angell is a man of noted ability in expert electrical work, being thoroughly well versed in all its branches, and further is highly appreciated by all his acquaintances. He has had a wide field of experience in the South in electrical and engineering matters in organizing and carrying out electric light and water works systems and plants. Mr. Bliss, so well and favorably known amongst the electrical fraternity, is paying especial attention to electrical investment business, dealing in electrical securities. Investors contemplating business of this kind should certainly give him a call.

THE ELECTRIC MERCHANDISE COMPANY.

The merchandise business of the Sprague Electric Equipment Company, Rialto Building, Chicago, has been purchased by a new corporation called the Electric Merchandise Company, whose offices hereafter will be at No. 11 Adams street, opposite the Pullman Building. This company in addition to continuing the merchandise business of the old company, will also manufacture and sell electric railway appliances for station, car and line work, of all kinds *irrespective of system*. Their experience in the Equipment Company has been such that they are peculiarly well fitted to recommend material which has been found by practical use to be the most satisfactory. Such connections have been made with Eastern manufacturers that in most cases goods can be bought at the same prices of the Merchandise Company as direct from the factory, time and frieght being saved, as all goods will be carried in stock. Catalogues will be furnished on application. Mr. W. R. Mason, so well known as the former general sales agent of the Sprague Electric Equipment Co., has been appointed general manager. In such hands, the business of the company will assuredly prosper, more especially as Mr. Mason and his staff will give great attention to the perfecting of details, which will lead to numerous and advantageous improvements in electric street railway work and equipment.

THOMSON-HOUSTON ELECTRIC RAILWAY WORK.

The Thomson-Houston Electric Co. opened their electric railway plant for public business at Salem, O., last week, and the local papers in expressing the sentiment of the people state that it is the grandest improvement which has yet favored their city.

The Thomson-Houston electric railway plant at Indianapolis, Ind., was to be opened to the public last week. The installation consists of 10 motor cars, to be operated over 6 miles of double track, the first 4 miles of which, leading out from the heart of the city, is equipped on the centre-pole method of overhead construction, with an ornamental iron pole in the centre of the street between the tracks. This is reported as being the most elaborately equipped road in the country. The new cars are the finest that could be constructed.

NEW YORK TRADE NOTES.

The Globe Fan Co. of 368 Broadway have a very pretty display of their fans, in their windows at the above address, one fan being run by a Crocker-Wheeler motor, and the wind from it drives several immediately under, showing the force of wind obtained.

Mr. P. B. Delany has lately removed to New Jersey, and is now building experimental works at South Orange. With his new facilities he may be expected to do a great deal of excellent work.

Mr. Emil Gabel, the eastern representative of the Ch. Munson Belting Co., of Chicago, has just taken an order for 119 feet of 48-inch three ply belting to be placed in the Philadelphia Illuminating Co.'s station, of which Mr. A. J. De Camp is the general manager.

NEW ENGLAND TRADE NOTES.

Wainwright Manufacturing Company, of Massachusetts, owing to their largely increasing business, have changed their offices from 34 Oliver street to more commodious and convenient offices on the second floor of the Vulcan Building, 8 Oliver street, Boston.

The Thomson-Houston Motor Company, have just published a most interesting little pamphlet entitled "The Thomson-Houston Motor," in which will be found a vast amount of useful information regarding the construction, utility, horse-power, necessary belt speed, floor space and dimensions of their electric motors. The pamphlet is handsomely got up, and contains an excellent cut of the motor.

The Gould & Watson Company.—No better exponent of the development of electric street railways can be given than the large orders received by the Gould & Watson Co., Boston, for their Molded Mica Insulators, which in the past week amounted to the remarkable sum of 50,000 pieces for line work alone. Further endorsement of the excellence of these insulators is not needed. This house furnishes by far the major part of the line insulators used in this country, and also does a considerable foreign business.

The New England Electric Company, agents for the Sprague system, have secured the contract for equipping the Manet Street Railway Company, of Quincy, Mass. This road will extend from Quincy to Howe's Neck, a distance of 3½ miles, and will be single track. There will be two motor cars of 30 h. p. each, and two tow cars. Mr. George F. Steele, is now president of the company, and Mr. Edward Blake, treasurer. The latter gentleman is soon expected back in Boston, having become convalescent from his protracted illness.

Mr. D. A. Andrews, Jr., of the firm of Pettingell, Andrews & Co., has started on a trip through the West, and will doubtless visit all the large cities. The business of this firm continues to increase in the most amazing manner, and the amount of business done for the past quarter is almost double the business done during the corresponding period last year. Messrs. Pettingell, Andrews & Company, have gone into the manufacturing of cut-outs, and general electric supplies, and are keeping a large pottery busy supplying them with porcelains. They will soon have on the market a complete line of porcelain cut-outs, fuse-boxes, rosettes, etc.

The Inter-Continental Telephone Company have received through Kidder, Peabody & Company the £35,000 from the Venezuela and Electrical Appliance Company, limited, for the sale of their rights in Venezuela to that company. The Tropical American Telephone Company having absorbed the Inter-Continental Company, get the lion's share of this sum. The Venezuela and Electrical Company have sent out about $25,000 of telephonic apparatus, and have placed orders since May 1st with the Tropical Company, the sole exporters of telephonic apparatus to South and Central America and West Indies, for telephonic apparatus amounting to $25,000.

The Electric Gas Lighting Company.—Mr. W. W. Burnham, of this company, is at present making an extended trip in Illinois and the West, and has recently secured a number of large orders for Samson batteries, among them being two orders for 1,000 batteries each. The Samson battery appears to be growing more popular than ever, an honest trial by customers never failing to result in more business and successive orders. The Electric Gas Lighting Company have just received 10,000 carbons from Paris, and there are 10,000 more on the way. The battery is well named "Samson."

The Brown Electric Protector Company of New England has been organized under the laws of the State of New Jersey with a capital of $50,000, for the manufacture and sale of the Brown electric protector. The officers of the company are as follows: William H. Smith, president and general manager; Robert Johnston, treasurer; Dustin Killicutt, secretary; directors, S. E. Barton, C. E. Bibber, Joseph H. Reall, William T. Brown, and the three officers of the company as above. All the gentlemen are well known in electrical circles, Mr. Smith being superintendent of the Mutual District Telegraph Company; Mr. Johnston, general manager of the Johnston Heater Company, and Mr. Killicutt being connected with the Simplex Electric Company. The protector is meeting with great success, and arrangements are now being made for their manufacture on a large scale.

Mr. Eugene F. Phillips, of the American Electrical Works, Providence, gave a very enjoyable clam dinner to Mr. and Mrs. John I. Sabin and daughter, of San Francisco, on June 4th, at the Ponham Club, Providence River. A special steamer was provided for the accommodation of the party, consisting of Mr. and Mrs. Eugene F. Phillips, Mr. and Mrs. W. A. Sawyer, Col. and Mrs. Keeler, Mr. and Mrs. E. B. Baker, of New Haven, Mr. and Mrs. F. E. Pettingell, of Boston, Mayor Henry F. Barker, of Providence, Mr. Henry Barker, Miss Jessie Barker, Miss Lincoln, Mrs. Hoxie, Mr. Thomas Doolittle, Mr. P. C. Ackerman, of New York, Mr. E. A. Smith, Mr. A. C. White, Mr. E. P. Phillips, Mr. F. M. Phillips, and Mr. C. Waggensein. Games of foot-ball were indulged in by the ladies and gentlemen, and the bowling alley was also well patronized. The dinner was served up in Mr. Phillips' usual magnificent manner, and enjoyed by all, who agreed that they had had a glorious time, and that Mr. Phillips was a king among hosts.

John Becker & Company, of 157 Pearl street, Boston, are manufacturers of name plates for almost every electric company. They have a large and compact brass foundry on the fourth floor of their building, and are constantly turning out new designs of name plates. The machine shop is fitted with every conceivable kind of machine, and Mr. Becker does not require to go outside of his shop for any part of the work. The steel engraving of the original plates is extremely interesting and is largely done by specially designed milling machines, which run at an extraordinarily high speed. The plates are bronzed or nickel-plated, as desired, and are turned out with a very superior finish. Mr. Becker has also a quantity of fine electric work in hand, and has a shop well adapted for the finest kind of work. This is evidently a growing business, and there is undoubtedly a large field for such work, where electricians can have their ideas carried out under the superintendence of a thoroughly mechanical expert.

Kendall & Slade are at present engaged on a very complete electric installation in a private residence on Beacon street, Boston. The house will be wired throughout for electric light—Edison system—electric bells, electric burglar alarm, electric gas lighting apparatus, speaking tubes, and also for motors. In the halls all the electric lights will be on separate fixtures from the gas lights. Automatic heater regulators will be put in throughout, and there will be motors for sewing machines, ventilating fan and passenger elevator. The current will be taken from the Edison tubes, and the whole job when completed will be one of the most complete in the city, the proprietor being determined to utilize electricity wherever possible. Kendall & Slade are also busy with supplies at present, and are making a specialty of cedar poles, which they furnish in great quantities and at very short notice. Among the cities which they have recently supplied with poles are Revere, Gloucester, Swampscott, Malden, New Bedford, Fitchburg and Dover.

WESTERN TRADE NOTES.

The Universal Radial Drill Co. have issued a very neat and tasteful calendar sheet for June. The front shows their foot lever countersinker or post drill, and on the other side are some descriptive details and a view of their works at Cincinnati.

Mr. Rose, of the Rose Electric Light Supply Company, 1106 Pine street, St. Louis, Mo., was in town this week. He reports business as booming and says he is selling a remarkably large number of second-hand machines and appliances. He expects to return to St. Louis in a day or two. Mr. Rose is a pusher and has worked up his large business by means of his energy and sterling business qualities.

Mr. George Cutter has issued to his many friends and patrons the following removal announcement: Removal—Mr. Geo. Cutter wishes to announce to his many patrons that he has transferred his stock of electrical supplies from 80 Adams street to 190 & 192 *Fifth avenue*, between Adams and Monroe streets, where he will be succeeded by the Great Western Electric Supply Company. He has now better facilities than ever for supplying the demands upon him and solicits a continuance of patronage.

Keelyn & Vandenburg is the title of a new firm just started for the purpose of establishing, buying and selling electric lighting, water works and power plants, with fine offices located at No. 185 Dearborn street, Chicago. The company is well backed financially, and parties contemplating business of this class may rest assured that it would be impossible to place it in better hands, as the above named gentlemen are well and widely known for their extended experience and ability in such matters, and all work they may undertake will be carried out in the best manner possible.

The Ft. Wayne Electric Company, 185 Dearborn street, have just completed the installation of a "New Wood" arc plant and a direct current incandescent plant for the Pennsylvania Railway Company's department in Chicago, which is spoken of in the very highest terms of praise by all those who have seen it. The plant is also utilized for charging the storage batteries used by the company, and is remarkably complete in all its various details. It is giving the greatest satisfaction right along. Mr. J. E. Keelyn, of the Ft. Wayne Electric Company, has closed a contract for an arc and incandescent plant for Lockport, Ill.

The Electrical Supply Company are as usual pushing ahead all the time. They are selling large quantities of Habirshaw wire, which has a great reputation for its durable qualities for interior work of all kinds in plaster and damp places. The Interior Conduits, for which they are the western agents, are meeting with enormous success and universal adoption. This is the one system needed to make interior wiring in buildings absolutely safe and to facilitate repairs of any kind; and it thoroughly fills the bill by rendering all the wires accessible at any time in the simplest possible manner. They are doing quite a brisk trade in their other specialties and supplies of all kinds.

Foree Bain has just received an order for four dynamos of 80 h. p. each, of his new pattern dynamo, illustrated in The Electrical Engineer of May 28th, several of which are in operation and giving the greatest satisfaction all around. There are numerous points electrically and mechanically about the machine which immediately recommended it, and the fact of its being designed by such a well known authority in electrical matters as Mr. Bain is a criterion that nothing will be left undone to produce a machine of the highest possible efficiency and finest workmanship throughout. These machines are to be employed in mining work, and certainly the field in this direction is one of the largest.

The Ft. Wayne Electric Company, of Ft. Wayne, Ind., have just issued a very handsome and tastefully gotten up catalogue of their Slattery induction system of incandescent lighting and their Wood arc system. It is beautifully illustrated throughout with cuts of the Slattery alternating current machine and exciter, the transformer, measuring and station instruments, switches, safety devices and lightning arresters of that system. The new Wood arc system is amply pictured, too, including the Wood dynamo, brush gauge, arc lamp, hanger boards, focusing lamps, electric headlight and central station switchboard. The descriptive matter is full of information, containing many points of interest, and is remarkably clear, setting forth very prominently the advantages belonging to the apparatus of the company.

The Knapp Electrical Works, Chicago, notwithstanding their recent disastrous fire, are now in good shape again, and have continued filling their large orders right along. Their Grimshaw wire is always in large demand, as its excellence and durability are thoroughly appreciated by all who have ever used it. They have just shipped one order of $6,000 worth of wire to Denver Col., and other orders of all sizes are coming in all the time. In their Perkins incandescent lamps they are also doing a large business and one which is continually increasing as the efficiency and durability of their lamps become more and more widely recognized all over the country. Mr. Knapp is feeling very pleased with the business he is doing and very hopeful with regard to the future. He pushes everything he takes hold of to its fullest extent and is a pretty hard man for his competitors to get ahead of.

SCHIEREN BELTING FOR ELECTRIC PLANTS.

C. A. Schieren & Co., of Ferry street, this city, are enjoying an enormous trade in their belting and specialties, and are pushing for more. They have not only continued to add to the long list of central stations in which their belts are used, but they have struck out with immense success into the newer field of electric railroading, where they have already found a large number of customers. The prospects are that they will not be able to enjoy much leisure this summer, but will have to put forth their utmost energy to keep pace with the trade they have worked up and are developing. Young Mr. Schieren reports some recent excellent work among electric railways in this part of the country.

W. H. LAHMAN'S SPECIALTIES.

W. H. Lahman, 156 Lake street, Chicago, patentee and sole manufacturer of the Lahman-Kirkwood fuel saving and dumping grate bars, reports his business good, and the prospect for the summer and fall trade as very encouraging. The local demand in Chicago has been somewhat checked by the prevailing strikes, which have affected all the building trades. These, however, are nearly ended, and a very brisk business may be confidently looked for during the remainder of the year. The managers of several large plants who have been experimenting with oil as fuel have announced their intention of returning to coal, and consequently to grate bars. We have been furnished by Mr. Lahman with the following partial list of the orders recently secured by him, including only those of thirty square feet and upwards: Barracks, Fort Riley, Kan., 150 ft.; Water Works, Town of Lake, Ills., 146 ft.; Water Works, Hyde Park, Ills., 121., ft.; Water Works, Jackson, Mich., 50 ft.; Water Works, Great Falls, Mon., 53 ft.; Fessenden Building, Chicago, 90 ft.; Commercial Bank Building, Chicago, 50 ft.; Fairbank Building, Chicago, 131 ft.; Graham School, Chicago, 44 ft.; Erie Flats, Chicago, 35 ft.; Pitkin & Brooks, Chicago, 30 ft.; Hammond Building, Detroit, Mich., 87 ft.; New York Life Building, Kansas City, Mo., 68 ft.; Post Office, St. Joseph, Mo., 55 ft.; M. E. Herbert & Son, St. Joseph, Mo., 60 ft.; W. Kirkup & Son, Cincinnati, O., 48 ft.; Carter White Lead Co., Omaha, Neb., 39 ft.; Gas & Electric Light Co., Steubenville, O., 30 ft.; Pure Ice & Cold Storage Co., Springfield, Ills., 30 ft., etc. Mr. Lahman will soon issue his annual illustrated circular, showing his recent improvements, with hundreds of additional references to his already extended printed list. He will be pleased, also, to give intending purchasers desiring the same special references to any description of plant or where different kinds of coal are used. Mr. Lahman is represented in Kansas City., Mo., by Messrs. English, Morse & Co.

THE RELIANCE GAUGE COMPANY.

The Reliance Gauge Company, of Cleveland, O., report a wonderful increase in the demand for their specialty, the "Reliance" safety water column, and have booked recent orders from the following: W. P. Pollock & Co., Youngstown, O.; Canton Electric Light Co., Canton, O.; Chandler & Taylor Co., Indianapolis, Ind.; Morgan Engineering Co., Alliance, O.; Murphy Iron Works, Detroit, Mich.; Wheeler Furnace Co., Sharon, Pa.; John T. Caulfield, Richmond, Ind.; Laidlaw & Dunn Co., Cincinnati, O.; Mutual Electric Light Co., Alliance, O.; Graves & Marshall, Dayton, O.; Standard Oil Co., Whiting, Ind., Cleveland, O., and Olean, N. Y.; National Tube Works, McKeesport, Pa.; Phœnix Iron Works, Meadville, Pa.; Lansing Iron and Engine Works, Lansing, Mich.; E. Keeler Co., Williamsport, Pa.; Atha Tool Co., Newark, N. J.; C. Stewart & Son, Worcester, Mass.; Cyclops Steel Works, Titusville, Pa.; Grainger & Co., Louisville, Ky.; Casey Boiler Manufacturing Co., Chattanooga, Tenn.; Forbes, Liddell & Co., Montgomery, Ala., and numerous small orders from all sections of the country. Another specialty is now being made by this company in the line of floats of all sizes for high pressure work, and they have recently made some 12-inch ones for the United States government which have to stand an external pressure of 175 pounds per square inch. They claim to be able to make floats capable of withstanding any required pressure on the same principle as the floats used in the "Reliance" safety water columns.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. IX. NEW YORK, JUNE 18, 1890. No. 111

Our varying hypotheses are simply the confession of our ignorance in a hidden form; and so it ought to be, only the ignorance should be openly acknowledged.—Faraday.

DAYTIME WORK FOR CENTRAL STATIONS.

NOT less deeply seated than it is erroneous is the old idea that a central station business is one limited to the hours of darkness, and that a plant can only be made productive and dividend paying by means of its nocturnal activity. Five years ago, in the meetings of the National Electric Light Association, the central station managers and superintendents of the country began discussing the possibilities of the motor field. To-day many of them are still in the discussion stage, and others whose companies have "Light and Power" in their corporate titles have done absolutely nothing.

Yet there are bright and shining examples of success in the endeavor to make a given district yield its utmost of revenue from electric power. One instance we have in mind is that of Mr. E. B. Greene at Altoona. This energetic young superintendent, in a town of about 35,000 inhabitants, now has in operation about 80 motors, ranging in size from an eighth up to 40 h. p. These motors take 70 horse-power of current, and he has just contracted for about 50 horse-power more. All these motors are on the incandescent circuit, and their returns are not the least important part of an income yielding a dividend that now crosses the 8 per cent. line, and has warranted a large extension of the plant.

Rochester, in this state, furnishes a good example of arc motor service. There the veteran Mr. G. A. Redman has no fewer than 508 motors running in a city of about 125,000 inhabitants. He maintains three distinct power circuits, but also has motors intercalated among arc lamps and series incandescents. These motors range from an eighth up to 15 h. p., and the higher limit will soon be 25 and 30 horse-power.

In both the instances mentioned above, the rates are moderate and the new business is judiciously worked up and encouraged. Mr. Greene, while running a planing mill with 40 horse-power, has found time to develop the ingenious notion of putting in a small motor to keep dry a vault where books are stored. Mr. Redman furnishes electric power to no fewer than 108 tailor shops, and he is proud of the fact that in one of the Catholic institutions the motor is wholly taken care of by the sisters. One of his motors keeps dry a cellar on the plan of starting the pump motor by a float that lifts as the water collects in a barrel. In another case the motor drives a blower at the soldering bench in a tinware factory.

These are among the brighter examples of the day, and we could only wish there were more of them. Still, the good work has begun and is becoming so varied that not only are a large number of stations on an earning basis the day and night around, but the year through. Of course the larger cities will generally be the best places for electric power distribution and will see a steady displacement of other power transmission machinery by the electric motor; but nearly every town large enough to maintain an ordinary arc or incandescent or combination plant is also large enough to keep a generator or two going during the hours of daylight. We hope more of our readers will not delay in giving the new industry a fair trial.

ELECTRICITY IN AGRICULTURE.

THE earlier experiments on the effect of electricity upon plant growth were attended with rather contradictory results, but we publish this week reports of later and extended trials in Russia, under official auspices, that are remarkably encouraging and must carry conviction. The article we print from Mr. Specnew details the various experiments with battery current, and shows that some of these at the Kief Botanical Gardens brought out the influence of the current in larger crops and the growth of enormous vegetables. The most successful trials, however, were those made in the government of Pskow, and as the averages obtained are those of five years, it will be seen that no hasty conclusions have been arrived at. In this series static instead of current electricity was employed. The general results were that the yield in seed and straw was greatly increased. Ripening was quicker and there was less tendency to disease. Potatoes, instead of being 10 to 40 per cent. bad, were only 0 to 5 per cent. It is noteworthy that the charge was collected from the atmosphere by means of rods bearing light crowns which were all united by means of wires. It is not mentioned, but we should imagine that such a system would not only be effective in combating the disease germs underground but in "scare-crowing" the ravagers overhead.

Evidently this is work that needs following up, and we would like to suggest that the Agricultural Department at Cornell University give the matter its attention. If by such simple means phylloxera and potato bug and army worm can be fought off, while the crops themselves can be increased without fertilizers, it is time that a great agricultural country like ours knew more about it and acted on the information.

SYNCHRONOUS TELEGRAPHY.

For more than a quarter of a century, synchronous telegraphy has occupied the attention of inventors, and from the early attempts of the Nestor of American electricians, Moses G. Farmer, down through the work of Meyer, La Cour, Delany and others, we have seen many beautiful applications to enable a number of operators to employ the same wire simultaneously. The synchronous action of two alternating machines coupled together, though observed many years ago, has, however, only recently been applied in telegraphy in order to obtain synchronism ; but it now seems destined to a wide application in this field. The latest and most improved method for this purpose is described on another page, and embodies the results of an immense amount of work and experiment on the part of Lieut. F. Jarvis Patten. As pointed out elsewhere, one of the chief advantages secured by the use of the alternating motor is the fact that it remains in synchronism by preference, and, indeed, of necessity, and from the experiments which we have witnessed we may say that it requires considerable effort to throw it out of unison. While it remains to be seen over what length of circuit exceeding one hundred miles the system can be operated without intermediate repeating stations, enough has been demonstrated to prove that for such distances sextuplex working is perfectly feasible. With repeating stations at suitable intervals and branches connected to the same synchronizing circuit, we can imagine an entire network of lines and instruments operated with the distributing brushes from Maine to California kept on the same segments by the impulses emanating from New York.

Demonstrating Specific Inductive Capacity.

Although the influence of the varying specific inductive capacity of different bodies plays such an important part in electrical work, it may be safely said that there are but few even among those whose work involves directly the consideration of this phenomenon, who have had occasion to witness an ocular demonstration of its effects. Indeed, to the majority of electricians, and to students especially, dielectric capacity is largely an abstraction, due to the fact that unlike other electrical phenomena, its demonstration in a clear manner has been lacking, owing to the want of the proper apparatus. The description of a simple method of exhibiting the phenomena involved in the action of dielectrics under the influence of a charge is therefore eminently timely, and in that given on another page Prof. Mayer again shows the great resources at his command as an original experimenter. Demonstrations of this nature go far towards the fixing of ideas, and the members of the New York Electrical Society, who, some time ago had the privilege of witnessing them, were unanimous in their expression of praise and delight.

Volcanoes in Cities.

During the past week New York City has been treated to the remarkable spectacles of Broadway, its main thoroughfare, belching fire and smoke and gas day after day. By a series of mishaps, repairs in the steam heating mains led to a rupture of the gas mains, and the ignition of the gas caused explosions in the electric subways and blew up the Fulton street manhole, as well as destroyed the cables passing through it. The blame for this state of affairs, which is at once dangerous and exasperating, has still to be fixed ; but wherever it lies it is safe to say that these explosions will go on, and that the electrical people will suffer. Such events are interpreted by many observers as meaning that the only or best solution of the subway problem for main streets networked with pipes is a large, well ventilated tunnel. We believe a tunnel will be built sooner or later.

Electric Traction Data.

At first very meagre, the data on electric traction is rapidly increasing, so that even now we are in possession of such information as will enable the engineer to predicate results with tolerable accuracy. This, however, is true more particularly of railways in which the overhead conductor in employed, and the many roads in operation in this country to-day afford ample facilities for observation and study. Up to the present time, however, there has been a great dearth of information on storage battery traction, which, though occupying a less prominent position at the present time, must in the nature of things assume prominence and obtain recognition in the future. Some time ago Mr. Anthony Reckenzaun visited this country in the interest of parties developing storag ebattery traction, and we are now placed in possession of some of the results obtained by him. His paper, read before the Old Students' Association, is replete with valuable facts and suggestions.

The Cost of a Municipal Plant.

It is interesting to note that the estimate furnished to the Common Council of Milwaukee, Wis., of the cost of a municipal lighting plant reaches the respectable figure of nearly $600,000. The raising of such a sum of money and the interest on it by taxation is hardly likely, one would think, to recommend itself to the citizens, when they are able to contract for all the lights they want, at a certain rate, and there end any responsibility or burden, as well as avoid the increase in the number of "mercenaries" that would follow the creation of a new city department under political control.

A Wiring Calculator.

Dr. Holmes once gave expression to the sentiment that mathematicians were not entitled to high consideration, in view of the fact that most of their work could be performed by the calculating machine, or the "calculating hand-organ," as he terms it. While this was evidently playful, and not meant to be taken literally, there is much truth in the idea when applied to ready methods of obtaining results by persons not capable of "handling figures" quickly. The calculation of the size of wires to carry currents with safety and with a given drop is one of the most frequently recurring in electrical work, and a handy calculator, such as that described elsewhere, will go far towards removing the doubt and anxiety of the wireman as to the correctness of his work. We are glad to welcome such appliances.

The Executive Committee of the National Electric Light Association met on June 16, and among other matters fixed August 19 as the date for the Cape May Convention.

PATTEN'S IMPROVED MULTIPLEX TELEGRAPH.

We are enabled to give in this issue a brief description of the Patten system of multiplex telegraphy as it is operated to-day on wires between New York and Philadelphia. As is probably known to our readers, it is a system of the synchronous multiplex type, depending for its operation upon the synchronous and uniform movement of two or more electric motors placed at distant points. In the present instance this is achieved by a novel application of the peculiar properties of electric motors, and the synchronism, far from being delicate, is powerful and reliable. The machine may evidently be of any size and power, and there is an evident tendency to run into synchronism instead of running out, which latter has been the case in former attempts at unison movements based upon the isochronous movement of a single machine. It is evident that an ordinary Siemens armature in a two pole field must reverse its current at every half revolution. If by any means two such machines be caused to reverse their armature currents simultaneously, they would necessarily move in synchronism.

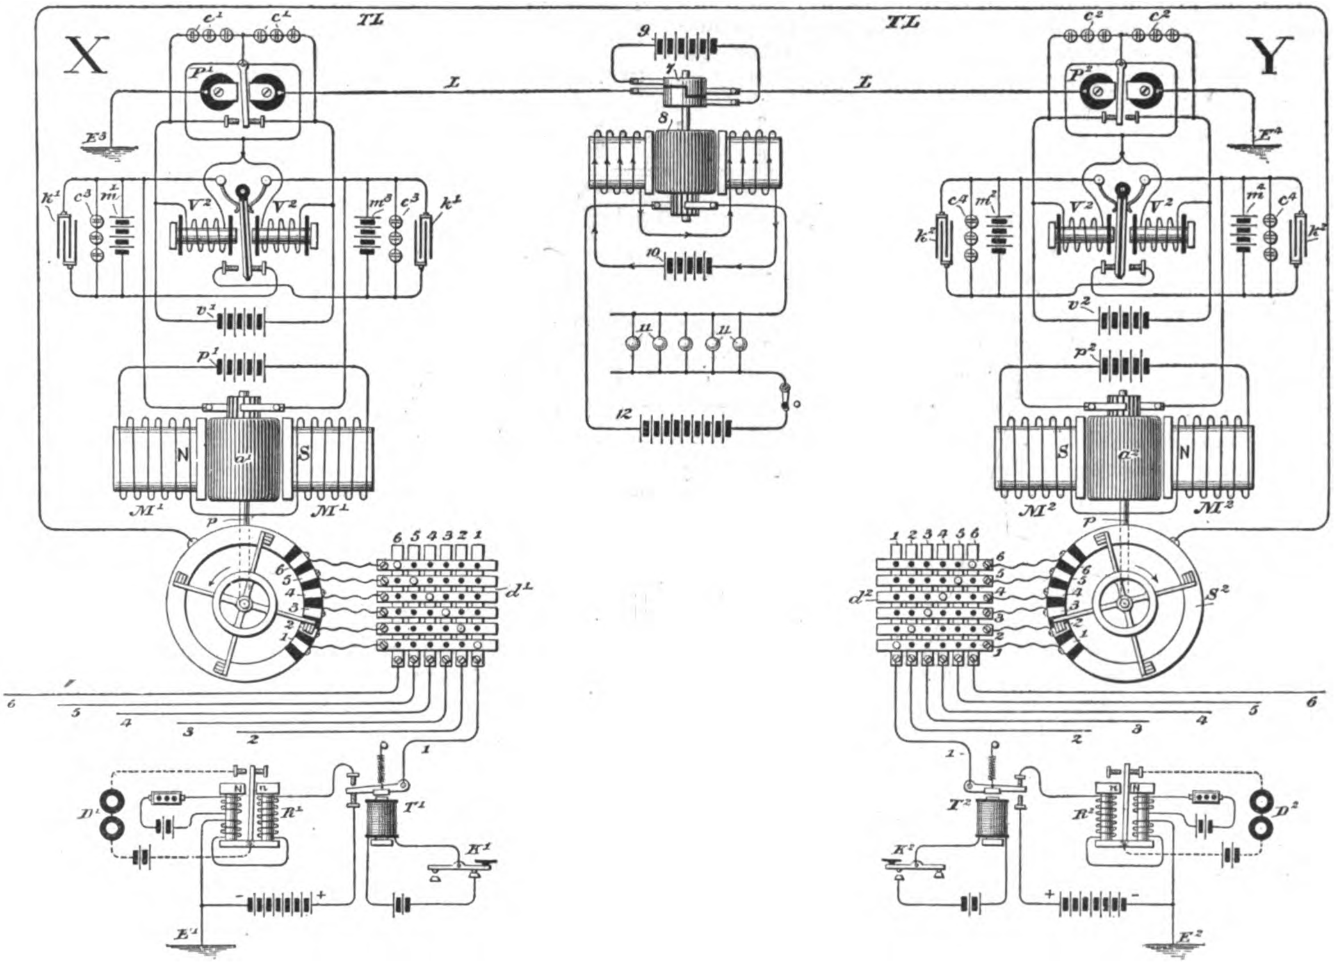

Fig. 1.—Patten's New System of Multiplex Telegraphy.

The apparatus used in the Patten system is simply an elaboration and practical application of this idea. Two electric motors at distant points are made to revolve in synchronism by causing the currents in the armature circuits to be simultaneously reversed through the agency of a controlling line current. The system will be readily understood from the illustration, Fig. 1, which is a diagram of all the operative circuits, including two terminal stations. The system is operated both as a single and a two line system. In the two line system a single synchronizing line is used for controlling a movement of electric motors, and may be used to synchronize the motors for any number of lines. In the single line system the synchronizing current is used both for synchronizing and telegraphing, without either function interfering with the operation of the other. For the sake of simplicity the two line system is selected for description.

In Fig. 1, X and Y represent two terminal stations of a telegraph line. The synchronizing line L L extends from the earth E^3 at X to E^4 at Y, reversing the polarized relays P^1 and P^2 at these stations. At any intermediate point in the line, whether at Y or X, or midway between, is placed a revolving pole changer, the function of which is to constantly reverse a current on this line derived from the synchronizing battery 9. This pole changer is driven by an electric motor having independent field and armature circuits, by which means its speed may be regulated and controlled; it is shown in the middle of the diagram. The lamps 11 are in the armature circuit in multiple arc, and by turning them on or off, the speed of the pole changer may be varied, the field remaining of uniform intensity excited by the battery 10. This pole changer sends rapidly reversed currents continuously to line, and maintains the polarized relays at X and Y in constant and rapid vibration. They necessarily beat in synchronism and are reversed by every half revolution of the controlling motor. These alternations set the pace of as many machines as it may be desired to place in circuit. Very little current is used for this purpose, the battery line on a 100 mile circuit having only about 30 volts potential. The current is necessarily very weak and the vibration of the polarized relays is delicate but constant.

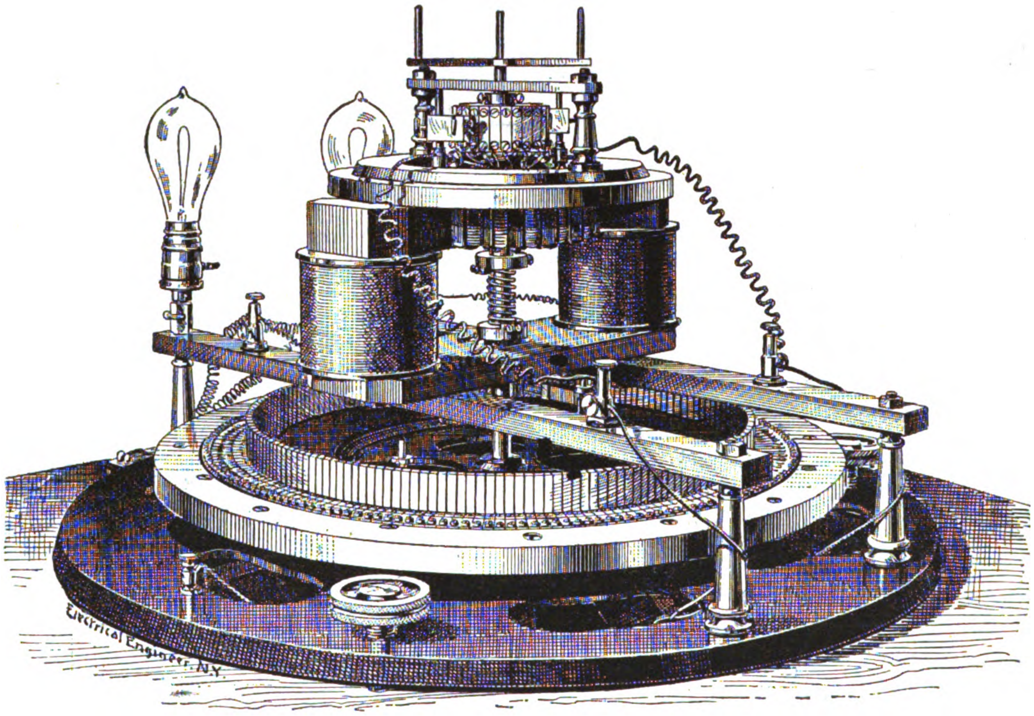
The armatures of these polarized relays could not carry sufficient current through their contact points to drive motors of any size or power, because of their lack of power to prevent sticking and welding at the contact points that would be occasioned by the making and breaking of such currents.

To overcome this difficulty they are caused to drive a powerful vibrator in the same way that a relay actuates a sounder, the vibrator being placed upon a local circuit of low tension V^1 V^2 and this is given sufficient strength and a suitable form to both rapidly reverse and convey the heavy currents of the motor armatures. These vibrators are shown at V^2 in the diagram which is sufficiently clear to explain their operative parts. The polarized relay as it vibrates to and fro places alternately one side and the other of the vibrator in circuit, and its armature is rapidly and strongly pulled first against one contact point and then the other.

The slight spark at the relay points is completely overcome by the liquid condensers C^2 placed as a shunt around these points. With a small current this device is in every way sufficient to prevent any welding or sticking of the points. Not so, however, with the vibrator points. The armature current of the motors, being about 8 amperes at 16 volts, the pressure is sufficient to cause a heavy spark and flame at the breaking of such a current and to weld the armature to the vibrator points, and much time and labor was required to effectively overcome this difficulty. It may be said, however, that this current is now broken continuously at the rate of 800 times a minute without producing a visible spark, and welding never occurs. This, which has been one of the greatest difficulties of the system, was effectually overcome by the system of devices shown. These consist in a special arrangement of liquid and plate condensers placed in parallel as a shunt around the armature points. Neither of these will suffice alone, and only a proper and particular combination of the two will effectually kill the spark. This combination has been found as the result of experiment, and it will suffice to say that the liquid condensers are very large. It will also be observed from the system of circuits that there is always a closed circuit for the batteries M^2 and M^4, which are alternately placed in the armature circuit in opposite directions.

It being now understood how the regulator at some intermediate station keeps the polarized relays in unison movement, and they in turn maintain the local vibrators in corresponding unison movement, it will be explained how this system of devices maintains the motors at distant stations in synchronous rotation. The motors are shown at X and Y by diagram circuits M^1 and M^2; the fields N S are constantly and separately excited by the batteries P^1 and P^2 while the armatures receive their current alternately in opposite direction from the batteries M^1 M^3 at X and M^2 M^4 at Y as the vibrator armatures move to and fro.

The motor armatures are of peculiar construction, differing from a Gramme or drum armature in the manner in which the windings are connected to the commutator. With a continuous current they will not revolve in a constant field, but will vibrate back and forth ; but by reason of their peculiar connections to the commutator segments they will continue in rotation when supplied with a current of rapidly reversed direction, the connections being such that a constant polarity of the armature is maintained with reversed currents, provided the armature turns through a certain arc of the circumference at each reversal of the current. As the system is now used, they are so connected that they move one-fourth of the revolution at each reversal of current. The armature is therefore really moved a quarter of a revolution at each reversal of the vibrator armature. The synchronism is thus corrected automatically four times in each revolution ; it may be made eight or twelve, or more, if desired, but four answers all the requirements of practice, the synchronism being continuous and accurate to a 196th part of the circumference. The spindles of the armature have secured to them revolving trailer arms carrying brushes which sweep over the segmental distributors S^1 and S^2. They are shown flat in the diagram, for clearness, but are evidently at right angles to the spindles, which in practice are vertical, as shown in Fig. 2, which represents the machine in perspective.



Electrical Engineer, N.Y.

FIG. 2.—PATTEN'S NEW SYSTEM OF MULTIPLEX TELEGRAPHY.

The telegraph line extends also from earth E^1 at X to E^2 at Y, one set of instruments being shown in detail at each end. The circuit may be traced as follows, the operator at X being supposed to be sending, and the operator at Y receiving: From earth, E^1, through the line battery positive to line, transmitter contact T^1, switch d^1, segment No. 1 of the distributer, and through the trailing brush to the large segment of the distributer, to which the line is connected at X; thence over the telegraph line T L to the same distributer parts at Y, out through the switch d^2, transmitter back contact, receiving relay R^2, and completing the circuit at E^2.

Among the many novel features in the systems is first the fact that the distributer is not necessarily cut up throughout its circumference, as in former attempts at multiplex telegraphy, and there may be only as many segments as there are circuits to be used on the line. Thus a sextuplex is shown, and there are six segments in the distributer. In order, however, to acquire a sufficient number of contacts per second for each operator to maintain a practically continuous circuit, it would be necessary to connect No. 1 to four segments in the entire circumference, so that this instrument as well as all the others would receive four impulses of current at each revolution of the machine. The same result is readily accomplished, however, by using only one segment and placing four trailers on the spindle, so that one is always in contact with the segment, while the other three are connected to line by contact with the uncut portion of the distributer. This greatly reduces the cost of such devices.

The system of receiving instruments is also decidedly novel; a polarized relay is used as a receiving relay, but it is not operated with reversed currents as is usually the case. The polarized relay is indeed so modified that it can hardly be called a polarized relay, properly speaking, as by the modifications introduced it is made responsive to intermittent positive or negative currents. The system shown is worked with intermittent positive currents, and is also worked on the open circuit or English system, the receiving relays being rendered operative by putting battery to line from the opposite end, and breaking being effected by opposing the two equal line batteries at the same time from the opposite ends of the line.

One complete set of receiving and sending apparatus is shown at each end. Of course those connected to the main circuits 2, 3, 4, 5 and 6 are identical with those shown connected to the circuit 1. They consist of a key, a transmitter, and the receiving relay normally of the polarized form, but modified as shown in the drawing by the introduction of an extra energizing circuit around one core of the relay, this slight modification rendering the relay operative under the action of intermittent currents of one polarity or sign only. The sounder, D[1], by which the message is read, is operated in the usual way when the receiving relay is actuated by an incoming line current. A sextuplex is shown in the diagram, although excellent results have been obtained on a hundred mile circuit when connected as a "twelveplex." By reason of the fact that all the circuits are shown in the diagram complete as they exist in practice, the system has the appearance of complexity, but it will be readily seen that it is not really so when it is considered that all these circuits are simply magnets, and that there is but a single moving part in each machine, the motion of the vibrators being so slight as to be scarcely noticeable.

In the motor machine, Fig. 2, the segmental distributer is near the base of the machine, which latter is supported by leveling screws by means of which the axis of the armature and revolving fly-wheel can be brought to a true vertical position. The distributer is about 15 inches inside diameter, and has vertical cylindrical walls against which the trailing brushes sweep as they are carried around by the heavy fly-wheel which can be seen inside the distributer. An interior contact is thus obtained, and the tendency is always to increase and preserve uniform contact of the brushes. The lamps are used as resistances in the field circuit of the machine.

A noticeable feature is the construction of the spindle, which is in two parts, the upper and lower halves being connected with each other by a spiral steel spring, as shown. The purpose of this is to prevent any sudden jerk or change of speed of the motion of the fly-wheel, although such a change of speed might happen to the armature; it also facilitates overcoming the inertia of the heavy fly-wheel at starting, this wheel weighing about 20 pounds. The base is open at the bottom so that the fly-wheel can be removed downwards through a hole in the table. The brush carriers of the armature rest in a similar circular frame at the top, which can be removed by lifting it out of place. The entire machine may thus be dismantled without removing any screws or using any tool. When the fly-wheel has been taken out the distributer is lifted off its carriage and slid out sidewise.

The speed is so regulated in practice as to give each instrument, when its circuit is closed, 30 contacts with the line per second, which, admitting four contacts per revolution, would mean an average speed of 7½ revolutions per second, or 450 per minute. But as the distributer motors move at half the speed of the controlling motor in the middle of the line, this one, which carries the pole changer, is driven at about 900 revolutions per minute, producing therefore 1,800 reversals of current per minute on the synchronizing line, and a corresponding number of vibrations of the polarized relay armatures. But as four of these are required to produce a single revolution in the armatures in the distributer motors, their speed is brought to about 450, as stated.

One peculiarity will be observed, namely, that this is not a terminal system as is necessarily the case where isochronous machines are depended upon for preserving synchronism. It is evident that in the system here described any number of polarized relays might be connected in the synchronizing line, and they would maintain as many distributer motors in synchronism. The movement of the machines and synchronism is very hardy as would naturally be expected, the motors exerting about one-eighth of a horse-power. The machines may be disturbed and lifted off their base and allowed to drop, without disturbing the synchronous movement. The trailer arms may in fact be struck and the synchronism disturbed, but unless the machine is completely stopped, it will soon come into synchronism again, as there is a tendency to automatically correct the motion, which is measured by the power of the machine itself, having little or no load to carry other than that due to friction and the grinding of the brushes against the walls of the distributer. By using machines of such power, however, these contacts are made very secure and reliable. Under ordinary conditions of line and weather the system will work at "twelveplex" on a good one hundred mile circuit with reliability and decision, the circuits being practically so many independent lines.

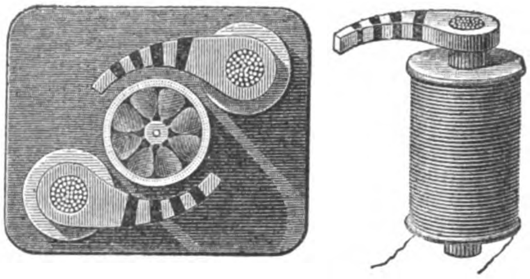
HUYGHEN'S GEARING IN ILLUSTRATION OF ELECTRIC INDUCTION.

At a meeting of the Physical Society, held May 16, Lord Rayleigh exhibited and described an arrangement of "Huyghen's Gearing in Illustration of Electric Induction." This gearing consists of two loose pulleys mounted on the same axle, with an endless cord laid over them, the loops or bights of which carry weighted pulleys, whose planes are parallel to the axis on which the upper pulleys turn. If one of the latter pulleys be started to rotate, the other one turns in the opposite direction until such time as the speed of rotation of the first becomes constant. Whilst this constant speed is maintained, the second pulley remains stationary, one weight being raised and the other lowered, but on retarding the motion of the first pulley, the second commences to turn in the same direction as the first. It will be noticed that the phenomena are analogous to those which occur in electric induction, where starting or increasing a current in one circuit induces an opposite current in a neighboring circuit, whilst decreasing or stopping a current induces one in its own direction. Lord Rayleigh pointed out that in this apparatus there is nothing strictly analogous to electric resistance, for the friction does not follow the same law. The analogy, he said, was complete as regards there being no change of potential energy, and the mathematical equations for the kinetic energy of the system are precisely the same as those given by Maxwell for electric induction.

THE WRIGHT-FERRANTI ALTERNATE CURRENT METER.

At the close of a lecture delivered by Dr. Fleming before the London Society of Arts on the alternate current phenomena recently described by Prof. Elihu Thomson before the American Institute of Electrical Engineers,[1] the lecturer showed a new alternate current meter designed by Messrs. Arthur Wright and S. Z. de Ferranti. As shown in the accompanying engraving, it consists in its latest form of a pair of vertical electro-magnets, the magnets having divided iron cores. To the poles of these magnets are attached curved horns of divided iron which lie in a horizontal plane. These curved horns are magnetically throttled at intervals along their length with copper bands. The curved horns embrace a circular space in which can revolve a light copper or iron shallow cylinder of thin metal. This cylindrical band forms the periphery of a light wheel capable of rotation on a vertical axis. Geared to this axis is a counting mechanism. The axis also carries a vane having mica blades.

The electro-magnetic principle said Dr. Fleming, may be briefly described thus: The throttling of the curved iron horns causes the rapidly reversed magnetism to take the form of a lateral diffusion of lines of force from the sides of the horns. In effect a series of oppositely-named magnetic poles travels along the horn from the base, where it is in contact with the top of the electro-magnet to the tip. These poles are represented by a series of bunches of lines of force, setting out laterally from the sides of the horn, and traveling up it. The lateral passage of these lines of force through the metal band which forms the rim of the movable wheel generates in it eddy currents. These are continually repelled by the moving field producing them, and hence a motion of rotation is given to the wheel by the alternating magnetism of the magnetic poles.



Figs. 1 and 2.—The Wright-Ferranti Meter.

The speed of rotation, being retarded suitably by the vanes, can be made to be proportional to the current strength of the current exciting the magnets, and hence the total turns of the wheel in a given time to the total electric quantity flowing through the meter.

OPTICAL TELEGRAPHY.

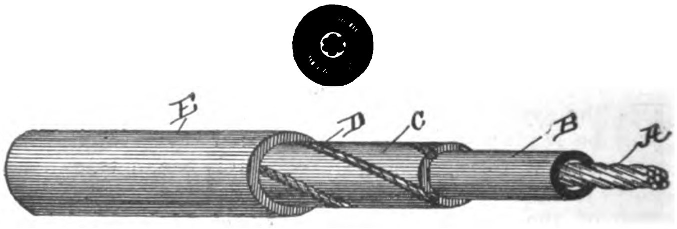
The flashing of a message from Mt. Reno to Mt. Graham, 125 miles, by aid of the heliograph, marks the greatest achievement in this method of optical telegraphy yet made. It is, perhaps, not generally known that the Signal Service Department has been making extensive experiments in this direction for several years, and it may now lay claim to having the longest and most complete heliographing line in the world. Its operations extend from Fort Stanton, in New Mexico, to Whipple Barracks, in Arizona, more than 1,000 miles, with ramifications leading in different directions. The terminal stations, twenty-five or more, connect with the general telegraph systems of the country, bringing the almost impenetrable reserves of New Mexico and Arizona into direct communication with civilization or the governments. The system is of immense advantage in Indian warfare, where ordinary telegraph lines have not penetrated, and where they could not be maintained in case of hostilities, were they set up. General Greeley recently sent a despatch to Washington from Bowie Peak, Arizona, the message being flashed from peak to peak, over gaps of forty-five miles, touching at Mt. Graham, Table Butte, Saddle Peak, Pinal Mountains, Lookout Peak, Baker's Butte, Squaw Peak, Bald Mountain to Whipple Barracks, from where it was transmitted by the ordinary system. The possibilities of the heliograph are not limited, however, to the 125-mile record, and understanding its value from a military point of view, the Signal Service Department will not fail to develop it as far as possible. The heliograph is a simple little instrument and easy of manipulation. A small mirror is set on a tripod in such a manner that the rays of the sun reflected from its surface may be thrown in any direction and kept at the point desired by mechanism compensating for the rotation of the earth on its axis. These rays, interrupted so as to show flashes of long or short duration, representing the ordinary Morse alphabet, are watched and their variations noted at the distant station.

THE NEW COBB CABLE.

We illustrate in the accompanying engravings a new type of cable recently brought out by the Cobb Vulcanite Wire Co., of Wilmington, Del., and designed especially for underground work. As will be seen, the metallic conductor A is inclosed in rubber tubing B made sufficiently hard to resist impression by the weight of the conductor.

About the hard rubber tubing there are wound spirally cotton cords which are embedded in a soft insulating material C, such as paraffin; this upon hardening becomes sufficiently tenacious by exposure to resist attenuation or impression by the weight of the material inclosed within it. The whole is finally covered by a tube of hard rubber to resist abrasion in the manipulation of the wire, such as the drawing in and out of conduits.

In the manufacture of the cable Mr. Cobb proceeds as follows: The conductor A, inclosed in its insulating material B, is first wound with the cord D, which is preparatorily soaked in an insulating compound, such as paraffin. The outside insulation E is then applied in the form of the rubber tubing referred to, through which the combined elements A, B, and D are drawn, the spirally-wound cord D serving to centre them inside the tubing, and thus permit of the application of the soft insulation C in an equal thickness throughout its entire extent, and which is applied by forcing paraffin, reduced to a liquid condition, through the length to be treated between the insulating parts B and E, the paraffin thus embedding the cord.



The New Cobb Cable.

Among the particular advantages claimed for the wire are that it affords extraordinarily high insulation; that as the insulating medium is formed in separate layers or thicknesses the joints in the several thicknesses of the parts B and E may, in producing desired lengths of the wire, be formed out of coincidence with each other, thereby reducing the possibility of leakage at the joints; that the requisite flexibility of the wire is not prevented by the comparatively great thickness of insulation employed, which, if entirely of hard rubber, would be undesirably stiff, and that any flaws that may exist in the parts B, C, and E are not liable to coincide, thereby affording a practically flawless insulating-covering for the conductor A.

---

ON THE PERMEABILITY OF IRON AT RIGHT ANGLES TO THE DIRECTION OF MAGNETISATION.—II.

BY A. E. KENNELLY.

The theoretical relations existing between the inductances may now be considered.

Let a magnetizing force $\mathbf{H}$ act upon a portion of homogeneous iron in the direction of X, a rectangular co-ordinate axis, and induce a magnetization of amount $\mathbf{I}$ in the same direction according to the relation, $\mathbf{I} = f(\mathbf{H})$. Then the induction per unit area $\mathfrak{B} = \mathbf{H} + 4\pi f(\mathbf{H})$, and a closed solenoid surrounding a ring of this iron will, when measured with feeble currents, show an inductance $\mathbf{L}_x$, expressed by the relation $\mathbf{L}_x = l\dfrac{d\mathfrak{B}}{d\mathbf{H}}$, l being the coil's inductance in a medium of unit permeability. Hence the locus of $\mathbf{L}_x$ referred to $\mathbf{H}$, should be a curve whose ordinates are proportional to $\dfrac{d\mathfrak{B}}{d\mathbf{H}}$ at every point.

If now $\mathbf{H}$ receive a small increment $d\mathbf{H}$ at right angles, or parallel to the Y axis, then, provided that the iron is isotropic, the resultant magnetic force will lie in the plane $X\,Y$, and make an angle $\tan^{-1}\dfrac{d\mathbf{H}}{\mathbf{H}}$ with X. The component magnetization will be $\mathbf{I}_y = \dfrac{d\mathbf{H}}{\mathbf{H}} f(\mathbf{H})$; the corresponding induction, $\mathfrak{B}_y = d\mathbf{H} + 4\pi\dfrac{d\mathbf{H}}{\mathbf{H}} f(\mathbf{H})$; and the apparent inductance of the original solenoid $\mathbf{L}_y = l\dfrac{d\mathfrak{B}_y}{d\mathbf{H}} = l\left[1 + 4\pi\dfrac{f(\mathbf{H})}{\mathbf{H}}\right] = l\,\mu$; where μ is the permeability of the iron in the direction X. The locus of $\mathbf{L}_y$, referred as before to $\mathbf{H}$, will therefore have its ordinates everywhere proportional to μ.

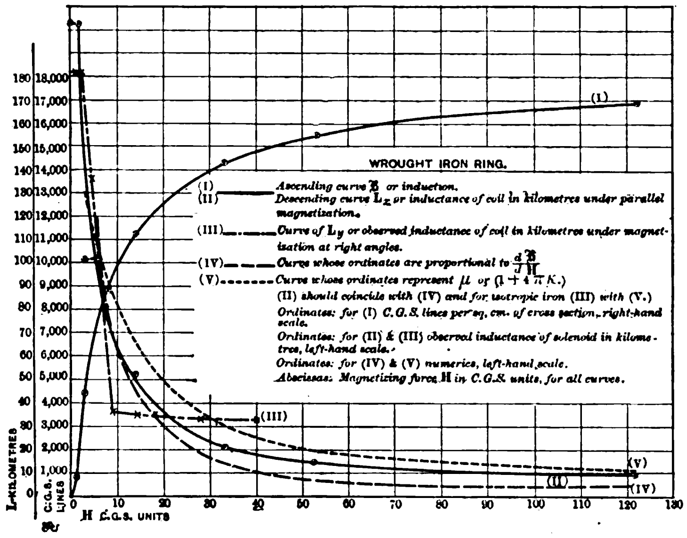

FIG. 3.

If, however, the iron is æolotropic, the magnetization along Y will be some function $\varphi(\mathbf{H}, d\mathbf{H})$ of both $\mathbf{H}$ and $d\mathbf{H}$, so that any evident divergence between these two curves of $\mathbf{L}_y$ and μ, shown by experiment, marks the departure of the iron in corresponding degree from the initial isotropic state.

The results given in Tables III.-VI. are plotted in Figs. 3, 4 and 5.

Examination of these curves shows:

1. That the curves of $\mathbf{L}_x$ do not indicate the very sudden rise in the value of $\dfrac{d\mathfrak{B}}{d\mathbf{H}}$ known independently to take place within the first 10 units of $\mathbf{H}$. This may perhaps be accounted for by supposing that at this stage the iron molecules are in a critical magnetic condition, and that the feeble magnetic force in the inductance test is insufficient to precipitate them.

2. That after $\mathbf{H}$ exceeds some 30 units, $\mathbf{L}_x$ appears in each case to be greater than $\dfrac{d\mathfrak{B}}{d\mathbf{H}}$. This can only be attributed to error in the observation or method.

3. That in Figs. 4 and 5 the curves of $\mathbf{L}_y$ for values of $\mathbf{H}$ not less than 50 are rather more divergent from those of μ than $\mathbf{L}_x$ from $\dfrac{d\mathfrak{B}}{d\mathbf{H}}$.

4. That in (Fig. 3) the case of wrought iron there is a marked discrepancy between the two curves $\mathbf{L}_y$ and μ, the former being considerably in excess for magnetizing forces above 20, and repetition of the experiment has checked this result. The point of abrupt change of curvature in $\mathbf{L}_y$ appears to take place at a magnetizing force of 9, and this, by a curious coincidence, is the value given by Mr. Shelford Bidwell for the "Villari critical point" in a particular instance.

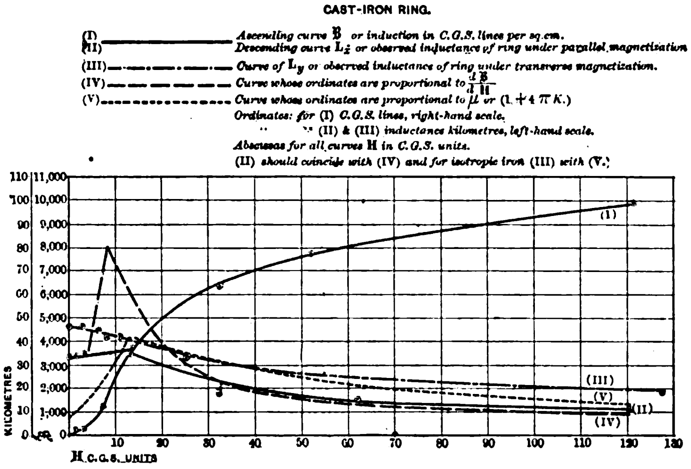

FIG. 4.

While, therefore, the results with the rings of cast iron and tool steel are doubtful, it may be safely inferred that the sample of wrought iron distinctly indicated æolotropic behavior for magnetizing forces exceeding 30 units, and this is not unreasonable when we remember that according to Dr. Hopkinson, iron attains its maximum length at a magnetic force of 20. The contraction which sets in after that point may do such work against intermolecular forces as will by reaction affect the ratio $\dfrac{f(\mathbf{H})}{\mathbf{H}}$, or K.

If this be admitted, Weber's theory cannot be regarded as theoretically correct for values of $\mathbf{H}$ exceeding 30, and beyond that point at least, any strict theory of magnetization must involve a consideration of molecular stresses and displacements.

Weber's theory, however great a stride over pre-existing conceptions, and however completely it enabled existing knowledge to cope mathematically with the intricate phenomena of magnetization, is based upon what appears to be a very arbitrary hypothesis. It assumes that the restituting force on the molecule varies directly with the sine of the displacement angle. The mechanism by which any such forces—magnetic or mechanical—could be exerted, unless as the result of some underlying hypothesis, is difficult to imagine. The amendments that Clerk-Maxwell introduced to enable it to cover the phenomena of hysteresis and permanent magnetization, ingenious as they are, must also be confessed as very arbitrary. While his limitations of strain and "set" in the rotation of the molecules are perhaps the only ones capable of yielding a mathematical solution moderately simple, yet rationally complete, it tasks the imagination to suggest why just those particular limitations should naturally suggest themselves.

Moreover, the appearance in certain conditions of a stage of magnetic instability at which the ratio of magnetization to magnetizing force suddenly becomes discontinuously great, such a condition as has been observed by several physicists, and lately pointed out by Profs. Ewing and Thompson, cannot be accounted for by the Weber-Maxwell theory in its existing form, which only admits of continuous changes.

It is usually much easier to discover imperfections in existing theories than to replace them by others less objectionable, but the following theory is offered as a suggestion. It is in reality only an adaptation of that promulgated by Prof. D. E. Hughes in his papers to the Royal Society ten years since. In the following form, while embracing all those phenomena that Weber's theory explains, it has the advantage of explaining the stage of molecular instability, without being cumbered by special inherent limitations in the direction and magnitude of the restituting forces. At the same time it has the disadvantage of so attempting to portray the operations concerned in magnetization, that a complete mathematical solution of the phases in transition is at present apparently beyond reach. It is also subject for its existence to the admission of an unusual postulate on interpolar distances to be later specified. We may call it the "chain" theory of magnetization.

Suppose the iron to be homogeneous, and to have n molecules per unit volume. As in Weber's theory, let the magnetic moment of each molecule be m, which varies only with the temperature. The maximum magnetization possible is then $I = nm$.

In virgin iron under no magnetic influence these molecules will be so arranged that there will be no resultant magnetization. This we may suppose to result, not from any indiscriminate scattering of the magnetic axes in space, but from the formation under mutual attractive influences, of closed loops or chains in the molecules. These chains may interlace in every conceivable manner, some may bifurcate or trifurcate in parts; but the characteristic feature of the magnetic arrangement in soft virgin iron will be the existence of magnetic chains made of two or more, and usually many, molecules as the rule, and the existence of unchained molecules, isolated exceptions whose unstable condition renders them likely to fall into and form an offshoot loop of the nearest chain upon the slightest impulse. Let it also be granted that the seat of magnetic force is at the two extremities or poles of a magnetic axis connecting them fixed in the molecules and of length l, while the average distance, d, intervening between the opposed poles of adjacent molecules in a chain is small compared with l. It may be remarked that this assumption is not equivalent to making the average intermolecular distance small compared with the dimensions of the molecule, for in the absence of knowledge concerning the nature of molecules, we are at liberty to place their poles in their "ether envelopes," or external, it may be, to their own proper space, provided that their poles are in rigid connection with them. The tendency of the magnetic chains is to contract and reduce the average distance d, a tendency resisted by those forces which regulate the proportions and play of the molecular structure. This granted, it is easily seen that the magnetic moment of any one chain about any diameter as an axis will be small in relation to the moment of the molecule, while the chains being in all curvatures and azimuths, their aggregate moment in the mass must be vanishingly small.

Considering a single molecule in any chain, if r be the distance from one of its poles to any other pole in the mass, the magnetic force exerted between them will be a vector force ρ expressed by the relation $\rho = m^2 \, \mathrm{f}(r)$, where $\mathrm{f}(r)$ may, or may not, be the function of inverse squares holding for sensible distances. Then the forces which are active in determining the direction of our selected molecule, assuming it to be free to turn on its center in any direction, but to have the position of its center prescribed by structural forces, will be two resultant magnetic forces, viz., $\Sigma\rho_p$ on the positive, and $\Sigma\rho_n$ on the negative pole, the summation being made vectorially and extended to every pole in the whole system. Since, however, d is small compared with l, the effective sphere of attractive force is practically confined to the nearest one or two molecules along the chain, while the influence of neighboring molecules in other chains is a disturbing force generally small.

These two forces, $\Sigma\rho_p$, on p the positive pole, and $\Sigma\rho_n$ on n the negative pole, will be equivalent to a uniform magnetic field, vectorially h say, acting on our molecule in the direction of its axis, and a single force—vectorially φ, acting upon the molecular center tending to give it a motion of translation, which tendency is presumed to be held in equilibrium by the mechanical forces of the molecular framework. This equivalent field h, and single central resultant φ will exist for every molecule; and with reference to the chains, each h will be approximately tangent to the radius of curvature at that point, while φ will generally be directed towards the interior of the chain.

If now a vector magnetizing force, H, be brought to bear upon the system, every molecule whose axis is not parallel to H, will be magnetically deflected. Considering any single molecule, if its h remained constant, then its new axial position vectorially $\mathfrak{A}$, say, in space, would be in the resultant of h and H, or in line with the vector $H + h$; but since nearly every molecule which previously contributed towards its h has also slightly deflected, the real new axial position will be in the vector line $\mathfrak{A} = H + (h - \Delta h)$, Δh representing the secondary disturbing effect on h.

The angle of deflection included between h and $\mathfrak{A}$ will vary for each molecule, from zero for those originally in line with H, to a maximum, for those whose axes were originally nearest to a right angle with H. It is to be noticed that no matter what angle each chain may individually make with H, in parts or in planes, there will be always two, and often more than two, molecules opposite in each chain, originally set so nearly perpendicular to H that their deflections in that chain are a maximum.

Let us call these favored molecules of a chain the "leaders." Then if the chains were all composed of the same large number of molecules and similar in every respect, so arranged that however intimately they might be interlaced, no two chains ever approached within the sphere of mutual disturbing influence, the deflection of all the leaders would be equal, independent of the angle between their respective chain planes and H; for with all leaders h and H would be at right angles; h would have a common value; so also would Δh, and thus the deflection of each would be $\tan^{-1}\left(\dfrac{H}{h - \Delta h}\right)$.

It may readily be granted that what would then be rigidly true for an ideally homogeneous system, is nearly true by the theory of probabilities in a system partly subject to homogeneity, and partly left to fortuitous combinations; so that the maximum deviation would be nearly alike in all chains and equal to the average value of

$$\tan^{-1}\left(\frac{H}{h - \Delta h}\right).$$

As H is now gradually increased, all the deflections increase, but the increase is most rapid in the leaders to which we may therefore confine our attention. If h were constant, the restituting moment due to h would increase with the angle of deflection; but owing to the secondary disturbance Δh, this moment does not increase in proportion to the moment of deflection due to H. This continues until h has been so much reduced by Δh, that a critical point is reached, and first reached in the leaders, when an increment in H, and therefore in the deflection, makes the restituting moment—just previously a maximum—diminish. At this stage nearly simultaneous with all the chains, the leaders break from their neighbors and rotate into parallelism with H. These neighbors, whose deflections had been next greatest in value, suddenly deprived of support, suffer a large increase in Δh, are precipitated into dislocation, and the example thus set is followed under transmitted influence all along the line, till it terminates at the motionless molecules or nodal points originally parallel to H. The desertion of the leaders is thus the signal for the immediate disruption of the chains, which vanish without leaving a trace of their existence, and it may be that on the subsequent complete withdrawal of H, the associations, arrangement, and chains formed by the molecules under their once more ascendant mutual attractions may totally differ from those gone by.

If, now, elastic resistance to rotation be introduced as a factor, together with the stresses affecting the isotropic condition of the medium, the materials are present for suggesting every known description of paramagnetization.

A few of the leading consequences of the theory may be outlined, as follows :—

With a homogeneity of chain formation in marked degree, and very small resistance to rotation, the critical stage should be very pronounced, especially if the stresses produced by the magnetization are either absent or removed by opposite imposed stresses. Such magnetization would be almost entirely temporary, and there would be no coercive force. On first applying magnetic force, there would be a period of steadily increasing feeble magnetization, then a sudden bound of almost complete magnetization, followed by no subsequent change with any increase in magnetic force.

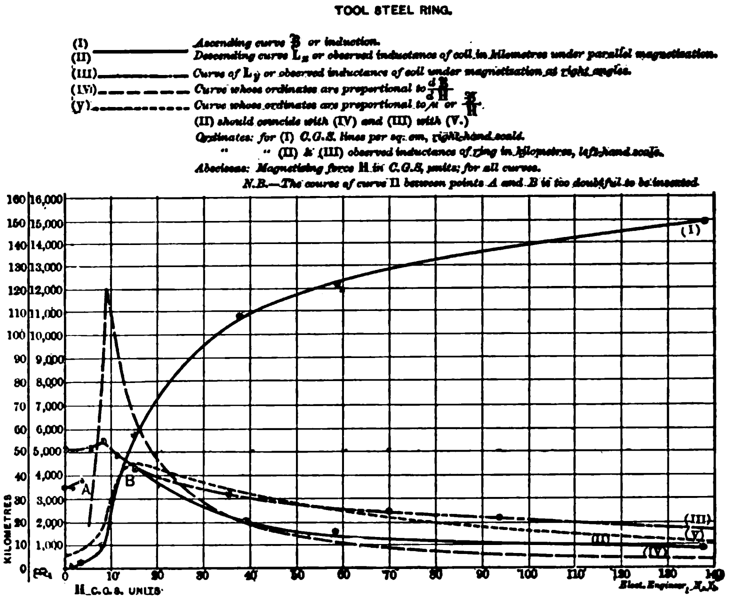

FIG. 5

If in the next instance elastic resistance to rotation were introduced, the first stage of feeble magnetization would not sensibly differ, and the critical stage would be reached at the same force, but the magnitude and duration of the bound would be modified in proportion to the resistance. The molecules would be retarded and the chains might not instantly or coincidently break up on the departure of their leaders. Even after the disappearance of the chains, infinite magnetic force would be needed to produce in every molecule an indefinitely close convergence to parallelism, and the parallelism once produced would be more or less subpermanent.

Finally as reaction stresses and want of chain homogeneity are introduced, the critical stage in the magnetization, although never entirely effaced, is more and more concealed, and the curve of $\frac{d\mathfrak{B}}{d\mathrm{H}}$ shows a lower and less tapering apex. Between these limits, all the characteristics of magnetized iron seem to be included.

As regards the stresses produced in iron, by the process of magnetization, we should expect to discover a voluminal expansion up to the critical stage owing to the reduction of the φ forces, which in the virgin state are directed towards the chain centers, as already noticed. Once the critical stage is reached, however, there should be a linear shrinkage in the direction of H accompanied probably by an expansion in all directions at right angles, owing to the mutual attraction of all the consecutive polarized molecules. This shrinkage should be instantaneous and final in ideally soft and homogeneous iron, while it would be gradually effected to an equal limiting amount in iron subject to elastic resistance.

This deduction appears to agree fairly with the observed facts so far as they are recorded for iron, but the anomalous behavior of cobalt and nickel in this respect has yet to be accounted for, and in fact as Dr. Hopkinson pointed out in his able address to the London Institute of Electrical Engineers, this year, no theory of magnetization can ever be considered complete until the origin and phenomena of molecular polarity, the essences of the whole subject, are satisfactorily explained.

THE LAURENT-CELY ACCUMULATOR.

THE special features of the Laurent-Cely accumulator, which is constructed by the Société Anonyme pour le Travail Électrique des Métaux, consists in the special nature of the lead paste employed, and in the manner in which it is applied to the plates. The active element is a mixture of chloride of lead and chloride of zinc. The fused chloride of lead has a density of 5.6 ; by incorporating chloride of zinc with it in certain proportions the density is reduced to 4.5. This mixture, brought to a state of fusion, is run into cast-iron molds in the form of small buttons with rounded edges. After cooling, the buttons are washed to remove the chloride of zinc, and thus to render them somewhat porous. Their density then varies from 4.2 to 3.4. The buttons which serve for the manufacture of the negative plates are then arranged in a metallic mold, into which antimonial lead is run ; this surrounds the buttons with a frame which holds them fixed in their positions. The negative plates are mounted in cells filled with acidulated water and provided with zinc electrodes. The composite and zinc plates are then short-circuited. The hydrogen which is disengaged upon the positive electrode reduces the chloride of lead, and there are thus obtained buttons of spongy lead of a density between 2.5 and 3.1, while that of ordinary lead is 11.35. The buttons used in the manufacture of the positive plates are first transformed into spongy lead, then heated in the air to oxidize them, and transformed into spongy litharge. They are fixed, like the negative buttons, in a frame of antimonial lead. The Laurent-Cely accumulator is employed for the lighting of the *wagons lits* on the Chemin de Fer du Nord, and has also served to drive a motor working an electric capstan.

A NEW FORM OF CHRONOGRAPH.

A new form of electric chronograph, due to the Rev. F. J. Smith, is described in the May number of the *Philosophical Magazine*. The instrument is original in many respects, although the time traces are made by means of electro-magnetic styluses, as is the case in many other forms of time-measuring apparatus. The principle involved in the construction is that of Attwood's machine A carriage, to which a sheet of smoked glass is attached, is impelled horizontally by means of a cord attached to a weight. The weight, after acting through a certain length of fall, is arrested by means of a table of adjustable height, and the carriage moves on with an acquired velocity which is found experimentally to be constant during the whole length of a trace.

SOMETHING MORE ABOUT THE ACTION OF THE TOEPLER-HOLTZ MACHINE.

BY ELMER G. WILLYOUNG.

In the issue of The Electrical Engineer for May 14th, there appears an article by Prof. Marshall Henshaw on the Toepler-Holtz machine and its theory of action; in this article Prof. Henshaw rejects an explanation published in *Science*, 1884, and recently republished in a special circular issued by Messrs. Queen & Co., as "hardly satisfactory" and publishes another which he proposes as a substitute. Prof. Henshaw fails to state, however, why he considers the first mentioned theory as unsatisfactory and what special advantages the proposed explanation possesses over it. A careful comparison of the two explanations will show that Prof. Henshaw's differs from that published by Messrs. Queen& Co. only in assuming that the sector D (granting it its initial charge) draws electricity of the opposite kind from the *discharging rod*, whereas the latter explanation assumes the sector as causing the same action at the diagonal comb e^1. The remainder of Prof. Henshaw's explanation is exactly the same as the other except that the various portions of the machine spoken of lie 45° behind the corresponding portions spoken of in the explanation published in *Science*, since the starting point itself is 45° behind.

The older explanation referred to is practically an adaptation of that offered by Silvanus P. Thompson, explaining the action of the old style Holtz machine. I do not know whether it was ever actually verified by Mr. Thompson or not; I feel quite sure, however, that Prof. Henshaw could not have verified his by experiment as the following will show:

JAS. W. QUEEN & CO. PHILA.

Action of The Toepler-Holtz Machine.

A machine was set up in the laboratory of Messrs. Queen & Co., and a many pointed metallic brush mounted upon an insulating stand so that it could be presented to the front of any portion of the revolving plate; this brush was connected by a long chain to a delicate electroscope some distance away. The plate was then revolved until sparks were given off by the discharging rods; it was then stopped and the two dischargers placed in metallic connection so as to eliminate any inductive action of the Leyden jars; the paper sectors and brushes were also thoroughly grounded. According to Prof. Henshaw's explanation the portions from e to b and from e^1 to b^1 of the revolving plate should not be neutral; presenting the points of the brush to these portions they were found to be strongly electrified, the upper one plus if the right hand discharger was plus, and the lower one minus, or vice versa if the left hand discharge was plus. In the same way the portions d to e^1 and d^1 to e which should be strongly electrified, if Prof. Henshaw is right, were found to be absolutely *neutral* though the electroscope was so delicate that it would indicate the electrification caused by lightly rubbing a vulcanite rod four feet distant.

A number of tests of the polarity of the machine were made at the same time as the above; out of thirteen successive tests, the rods in each case being placed in metallic contact for some time so that the jars might be thoroughly discharged before making the next test, six showed the right hand discharging rod to be positive; sometimes the rod would be positive and then negative and sometimes of the same polarity twice in succession. Tests were also made in rapid succession, so that there was considerable residual charge still remaining in the jars when the plate was revolved for the next test. It might now be expected that the polarity of the machine would continue the same; strange to say, however, the alterations were just as frequent as before.

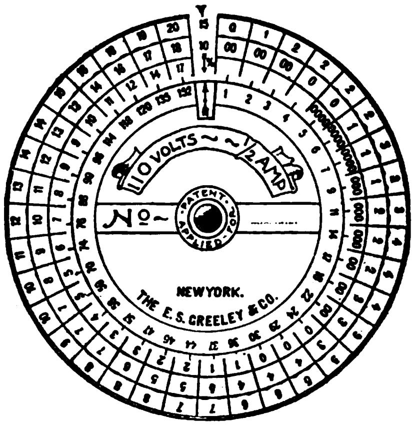

Fig. 1.—Greeley Automatic Wire Calculator.

Undoubtedly there is much to be desired in the way of an explanation of the action of this well known machine; the rapid development of the more practical applications of electricity has distracted attention from this as well as many other phenomena of great scientific interest. As far as I know, no one has yet made anything like such an experimental investigation of the Toepler-Holtz machine as is being made in the case of dynamos and motors dozens of times each week.

AN AUTOMATIC WIRE CALCULATOR.

The large increase in the number of public buildings as well as private dwellings, constantly being wired for electric lighting has necessarily put a large part of the work into the hands of somewhat inexperienced men, who, as a rule, are provided with charts in order to ascertain the proper size of wires to use for the various circuits carrying incandescent lamps, both within buildings and for the outside line work.

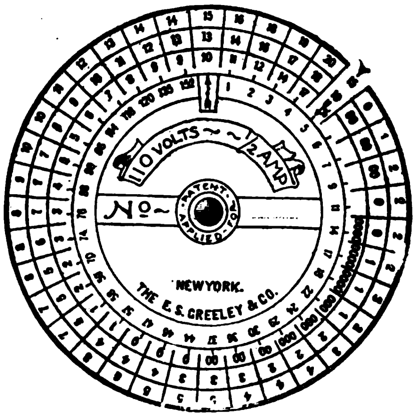

Fig. 2.—Greeley Automatic Wire Calculator.

To still further simplify the work of the wire man and to render his work reliable and accurate, The E. S. Greeley & Co., of this city, have recently brought out an "automatic wire calculator." This consists of two discs of stiff cardboard of unequal size, the smaller one being mounted in the centre of the larger and made to revolve thereon, as shown in the engraving, Fig. 1. On the back of the larger cardboard are full directions for the use of this unique and useful tool. The one shown in the above engravings is arranged for the calculation of wire for a 110-volt distribution, and we understand that there is also another one in preparation arranged for 55 volts.

The process of calculation is shown in the illustrations, Fig. 1 showing the two discs in their normal position and Fig. 2 showing the calculation determining the size of wire suitable for use to carry a current for 5,000 lamp-feet. The number of lamp-feet is obtained by multiplying the foot distance by the number of lamps; that is, 50 lamps at 100 feet, or 10 lamps at 500 feet, or 500 lamps at 10 feet, when multiplied one with the other give 5,000 lamp-feet. It is then only necessary to turn the inside dial until the figure 5 on the scale of the inside disc comes opposite the arrow which is upon the outside disc, which operation is shown in Fig. 2 of our illustrations. When this has been done the arrow upon the inside disc will point to the size of wire which it is desirable to use, and which in the accompanying illustration is shown to be No. 10 for a 5 per cent. drop, No. 13 for a 10 per cent. drop, and No. 14 for a 15 per cent. drop.

With a simple aid of this kind at hand, properly applied, there ought to be no difficulty in the proper proportioning of circuits even by the most inexperienced.

THE UTICA N. Y. BELT LINE ELECTRIC RAILWAY.

The Utica Belt Line Railway, which is herewith illustrated, has recently been put in operation under the Thomson-Houston electric railway system, and is a fine piece of construction which embraces more than a few conditions not found in ordinary electric railway construction work. The total length of the track is 20.37 miles, 15.84 miles single, and 2.27 miles double track. Seven and eight-tenths miles of single track is located near the curb line, on which the single bracket suspension is used, on the remaining track cross suspension is employed with one or two exceptions. There are 32 turnouts aggregating 6200 feet in length, 18 single and one double track curves, and eight steam railroad crossings. The maximum gradient is 3 per cent., and occurs at a distance of about 1500 feet from the power station, and extends a distance of about 300 feet. There is one curve with a 50 foot radius, which has a grade of 5 per cent. The power station is a handsome one story brick building, equipped with all modern conveniences, and necessary minor apparatus for a first-class power plant. It is well built, finely lighted, and the arrangement of the apparatus is admirable. At present three 200 h. p. Armington & Sims compound condensing engines are in place, and a battery of four boilers for supplying the necessary steam. The station is admirably situated as far as coal and water supply is concerned, the the water being obtained from a large canal on one side, while the coal is dumped directly from the steam railroad cars on the other side directly into the boiler room Six 80 h. p. Thomson-Houston railway generators are now in daily use. The station switch-board which contains the auxiliary electrical appliances is very handsome and finely constructed throughout. The car equipment consists of 25 cars, each equipped with two 15 h. p. Thomson-Houston railway motors. The power station, and, in fact, the entire installation, reflects great credit upon the railway company, which, from the start, manifested its determination to use only the best material and forms of construction. The successful operation of the road since its start has shown this to have been a wise plan.

THOMSON-HOUSTON ELECTRIC ROAD, UTICA, N. Y.

The Holyoke Water Power Company are to consider plans for enlarging the capacity of their electric light plant. The new contract for city lighting has been given to the company and additional circuits will necessitate an enlargement. The company's electric light station is now located in their Cabot street mill, but they will probably erect a new building. No plans have been discussed yet.

ELECTRIC TRACTION DATA.[1]

BY A. RECKENZAUN.

Of the various questions connected with electric traction, the branch to which I have the honor of calling your attention to-night, appears to me fundamental to a complete knowledge of the subject. It relates mainly to tractive force and mechanical resistances on tramways. It is a subject which is not as fully appreciated by electrical engineers as it should be, although it forms the very basis of street locomotion, and I venture to say that future improvements in the economy of electric traction will in a large measure depend upon minute attention to details relating to this branch of the science. The very existence of tramways as substitutes for the common road, is concentrated in one point, viz., the reduction of tractive resistance to a minimum.

It is a well-known fact that the traction expenses on horse tramways constitute about two-thirds of the entire working expenses, and it has long been the aim of engineers to find an economical mechanical substitute for animal power. Electricity has found great favor with tramway men in the United States, and there is every probability of similar developments in Europe at a not distant date. Improvements can only be brought about by experience, and experience must be gained in actual practice and by careful observation. These, again, can be supplemented by data obtained from those who preceded us, and it is my intention to bring, in a condensed form, such data, from which you will be able to draw your own conclusions, and which will guide you in future and progressive efforts.

In order to provide facility for traction, we must have a solid, permanent way, and excellent rolling surfaces. The practical value of a good rolling surface can scarcely be over-estimated. The rails must be rigid, parallel, and fixed to solid foundations. In America, flat step rails without grooves are used; these offer less resistance to traction than grooved rails, but, as a rule, they are not so solidly laid as English rails. According to Mr. D. K. Clark, the resistance to traction on an ordinary railway may be as low as 6 lbs. per ton; but so low a resistance cannot be obtained with grooved rails which are exposed to the incidents of mud, grit, stones and dirt, and which, moreover, have frequent and sharp curves.

Mr. Henry Hughes deduced from experiments on tramways a tractive resistance of about 26 lbs. per ton; often more, occasionally less. Such high resistances as these are readily accounted for, when it is considered that the flanges of the wheels frequently take a bearing on the bottom of the grooves, or on the dirt embedded therein, at the same time that the wheels roll on the surface of the rail; for thus the wheel rolls on two different radii simultaneously, and grinding of surfaces in contact must result. It may also occur that one wheel is running on its proper bearing surface, whilst the other, belonging to the same axle, has its flange touching the bottom of the groove, when by virtue of different circumferential velocities, additional friction is introduced. Sometimes the rails are a little out of gauge. All these circumstances augment the tractive force requisite with grooved rails. The horse, if it could speak, would be a good witness, but failing his verbal evidence, the dynamometer has been consulted. Better than the mechanical dynamometer, however, is the ammeter. A dead beat ammeter indicates instantly the slightest variations of tractive resistances, and I venture to say that it will be through the judicious and more frequent applications of this instrument that material improvements both in the permanent way and in the rolling stock of electric tramways will be effected.

Probably the most interesting and complete tests with horse cars were those made by M. Tresca. He proved, experimentally, that the groove in the rail was the direct cause of a large portion of the resistance to traction. An ordinary car with its four flanged wheels was propelled over the tracks of the Paris-Versailles tramway, and it was found that the average tractional resistance amounted to $\frac{1}{100}$ of the gross weight, or 22.4 lbs. per ton. Subsequently two of the flanged wheels, both on one side of the car, were removed and replaced by flangeless wheels, when the resistance, all other things remaining the same, amounted to only $\frac{1}{147}$ of the weight, or 15¼ lbs. per ton. The gross weight of car and passengers was 5.67 tons. These experiments show conclusively that at least half the power is wasted in friction between the sides of the groove and the wheel flanges.

The force required to start a tram car and to get up speed is necessarily greater than the force required to maintain a given speed uniformly. It was found that the starting force is from four to five times that necessary for running on the level road. Curves also increase the resistance very much. In dry weather, on curves of 50 feet radius, the resistance to traction is doubled, and on those of 35 feet radius trebled; but when the rails are wet, this resistance, due to curvature, is considerably reduced. Water, plenty of water, on the rails acts as an efficient lubricant, and you will see by statements later on, the general effect of wet rails. Short wheel bases, bogies, or radiating axles, render motion on curved rails easier, and flexible axle boxes are now greatly favored, especially in the United States, for the same reason.

The effect of gradients is a matter of simple calculation. It is the maximum gradient on a given line which determines the size and power of the electric motor. Allowing 22.4 lbs. tractive force per ton, we should have to exert a pull of 134.4 lbs. with a six-ton car on a level road. This, at the rate of seven miles an hour, or 616 feet per minute, would give us 2.5 horse-power effective on the axles. If we have to overcome a gradient of 1 per cent., or 1 foot in 100, the resistance due to gravity will also be 22.4 lbs. per ton, therefore we shall require about 5 horse-power to pull this car up a gradient of 1 in 100. With a 2 per cent. rise the power will be three times as great as on the level, and, roughly speaking, each per cent. of grade demands as much energy as the propulsion of a given weight on a horizontal road if the speed is to be constant. On steep gradients, however, it is customary to run slower, whereby some of the energy is saved at the expense of time.

The time at our disposal will not permit of descriptions of particular systems of electric traction, nor of the relative merits of each, and we shall confine ourselves entirely to statistics on tractive force, no matter how this force is transmitted; and we shall merely consider the question of moving a given load on a given track by means of the electric current. In order to ascertain the amount of energy used on electric cars I have made, in conjunction with the Electric Car Company of America, a long series of systematic tests both on an experimental track built for this purpose, as also on the public roads under all sorts of conditions of traffic. Whilst on the experimental track we could run at any speed we liked, and without stoppages, on the public streets we were confined to the speed of horse cars in front and behind us, besides taking up and putting down passengers and regulating our vehicle to the general traffic of some of the busiest streets of Philadelphia.

This experimental track was laid in an irregularly shaped yard as shown on the diagram Fig. 1, and it was intended to represent as difficult a line as is likely to occur in actual practice. Its entire length was 1,005 feet, the ends being so joined that the cars could circulate continually. Five and a quarter journeys round this track represented a mile run. There were four curves, two of 50 feet radius, one of 33 feet and one of 100 feet. Tangent with the 33 foot curve was a gradient of 4.98 per cent. rise, which descended on the other side at the rate of 5.8 per cent., and joined the curve with a radius of 100 feet. On this track we carried out tests and recorded observations which may be counted by the hundred thousands. The following figures relate to experiments made with a car in the autumn and winter of 1887–1888. The vehicle was an ordinary 16 foot two-horse car, with two axles, one motor and a set of storage batteries. It weighed, with several men on board, 5.3 tons; its wheel base was 6 feet, and one axle only was driven by an electric motor with intermediate spur gearing.

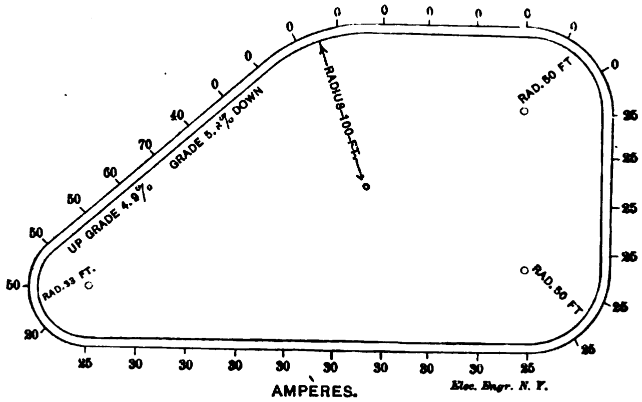

FIG. 1.

The rails were the ordinary American flat rails, grooved only at and near the curves, which represented a large percentage of the entire track. With a set of 84 cells of a nominal capacity of 150 ampere hours, this car made 230 trips round this track, representing an aggregate of 43.8 miles with one charge of batteries. The car was only stopped and started fourteen times. The actual running time was 6¼ hours, giving an average speed of seven miles an hour. At the commencement the electromotive force of the cells on closed circuit was 160 volts, and at the end 145.62 volts, the average from actual measurements was 157 volts. The maximum current used on the steepest grade was 70 amperes, at starting; on the curve or grade, it rose to as much as 120 amperes. The average current consumed was 22.6 amperes, which corresponds to 141 ampere hours taken out of the battery. The current on the level road fluctuated between 18 and 25 amperes. The diagram, Fig. 1, representing this track has marked upon it the current rates used at the various points of the journey. It will be observed that the car ran by momentum during a considerable portion of the journey, this momentum being acquired during its downward movement upon the 5.8 per cent. gradient, the brake being only slightly applied, and the stoppages during this experiment, as I have said, were few.

---

[1] Paper read on Wednesday, April 30th, before the Old Students' Association of the City and Guilds of London Institute.

A mean of 4.75 electrical horse-power was thus expended, giving a consumption of 29.69 horse-power hours supplied by the battery; and the maximum energy given off at any moment was 10,500 watts, or 14 electrical horse-power. Allowing an average efficiency of 75 per cent. in the motor, and 85 per cent. in the gearing, we obtain a total efficiency of nearly 64 per cent. between the motor terminals and the axle, or about 3 horse-power available for traction. Thus the mean tractive force throughout the 43.8 miles run was 160 lbs., or about 30 lbs. per ton. This is very low, considering that out of the entire distance we had only 21 miles of tolerably level track, the rest being made up of 3.4 miles of 33 feet curves, 7.07 miles of 50 feet curves, 3.64 miles of 100 feet curves and 4.05 miles of ascending grades of 4.98 per cent. On the other hand, there were 3.8 miles of descending grades of 5.8 per cent. which furnished momentum right along the 100-foot curve until the car passed completely into the upper 50-foot curve on the right hand side of the diagram. Converting the work into ton-miles, which is probably the most rational way of comparing figures, we get 5.3 × 43.8 = 232.14 ton-miles at an expenditure of 29.69 h. p. hours, and this gives nearly 7.78 ton-miles per h. p. hour. We have obtained much better results than this with a subsequent car containing various improvements, and, on one occasion, this larger car made 68 miles on the experimental track, each h. p. hour producing 10.9 ton-miles, but these are exceptional feats, and our present object is to consider practical results corresponding with every-day work—industrial results in fact.

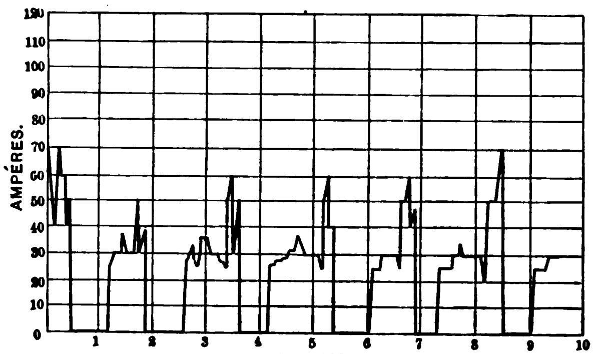

Fig. 2.

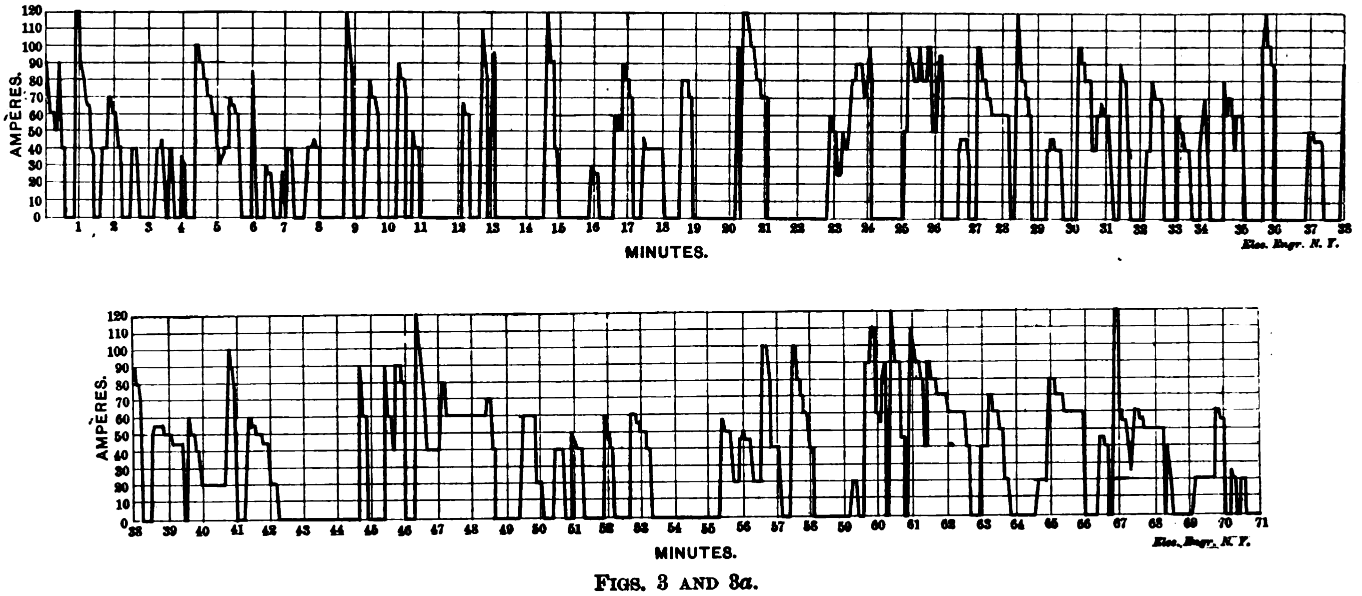
Three men, each well trained for his work, were necessary for these tests, and their respective duties were as follows:—One man took charge of the switch in front of the car and the hand-brake; in fact he performed the ordinary function of a driver, taking care that the car moved at regulation speed on the level, that it did not "race" down grades, nor go too slowly up the inclines, and that it took the curves with safety. The second man, with a timepiece in his hand counted the number of round trips and recorded the same; he also took voltmeter readings at equal intervals. The third attendant had the more difficult task of reading the deflections on the ammeter and writing down the values. In order to insure uniformity in the time between each reading, and also to take as many readings as possible, one has to learn to write down a certain number of figures in a given time, putting down ciphers, to fill up time when the ammeter needle is at zero. The number of observations written down during the 43 mile test were close upon 7,500, or one reading every three seconds. Considering the rapid variations in the current on uneven tracks, it is very important that readings are recorded at the shortest possible intervals in order to arrive at a correct average. The specific gravity of the cells was tested before starting, when they were fully charged, and it averaged 1.186. At the end of 6¼ hours, when the cells were practically discharged, the density fell to about 1.126. The accumulators were then recharged for 6 hours at the rate of 30 amperes, when the electrolyte assumed its original specific gravity. It is impossible to keep the acid in every cell at the same density; there are always slight differences, and we had to take the mean of the entire number of cells to insure accuracy. Diagram Fig. 2 represents the currents used during six journeys round the experimental track, and this was virtually repeated throughout the tests, except when stopping and starting. Now compare this with diagrams Figs. 3 and 3a, showing the current variations out in the crowded streets. You will observe a number of tall, narrow peaks running down to the zero line at frequent intervals. During these intervals the car was either stopping or running by momentum. The vertical lines in this diagram represent minutes and seconds, and the horizontal lines amperes measured on the car during the entire journey from 23d street to the Exchange in Philadelphia and back to the Graysferry depot, and from thence again to its starting point, a distance of about seven miles. Every corner on this diagram represents a movement of the switch by the driver.

The switch was constructed to throw the various distinct coils on the field magnets of the motor into parallel or in series, or into several intermediate steps, and these steps can be readily detected on the sharply defined junctions of the lines showing amperes. The average current consumed throughout this round trip, down town and back to the depot, amounted to 31 amperes. The weather was dry, windy, and the road very dusty. Allowing for this, as well as the frequent stoppages and slowing down in order to keep pace with the horse cars on the same line, it appeared that there must have been some waste of energy. The diagram shows that there was a continuous effort of getting up great speed at one moment and slowing down the next. It shows that the driver was somewhat nervous and inexperienced to driving in the public streets, hence the frequent alternate use of high currents and brake. The gradients on this road are not very severe; the heaviest is about 4 per cent., and several of 2 and 3 per cent. Calculating as before, and allowing the same efficiency, we should get an average tractive force of 39 lbs. per ton. The car in this case carried 23 passengers one way, and 30 on the return journey, giving a mean load of 7 tons.



Figs. 3 and 3a.

Numerous journeys were made through the city with this car, and some days after the above event I again took careful readings; the driver was more experienced, less nervous, never used the utmost electrical power at his disposal, and the average current during two round trips came to only 23.11 amperes. Twenty-five per cent less than formerly, under similar conditions of load, speed and weather. Although the average height of the peaks was less in this case, the number of them was nearly the same, and the gaps representing periods when no current was used gave, on being added up, 45 per cent. of the total. Thus for nearly half the time the car was running by momentum alone. It must be remembered that every few hundred yards there is a street crossing those we ran on, and all these streets have their tramways, so that for common safety it was necessary to slacken down at each square or block of buildings, even when other traffic and passengers did not impede our progress. These diagrams teach us two important lessons; one is, that a skilful driver can economize energy to a large extent; the other, that proper appliances for regulating the power within a wide range, are a distinct advantage.

After a good shower of rain the tram rails assume a tolerably clean appearance; the mud is then easily squeezed out by the flanges of the car wheels; thus I have observed that during. or immediately after a rainfall, the energy necessary for propelling a vehicle is considerably less than in dry weather. There is a positive saving of power amounting to from 15 to 50 per cent. with clean wet rails. By careful observations we were enabled to record the effect of various comparatively small obstacles on the rails; the ammeter showed the minutest variations in tractive force; it is far more reliable than a dynamometer, since it has neither friction nor momentum.

Snow is the greatest enemy of tramways; it offers the greatest resistance to traction. Anticipating snow storms, which occur rather frequently in some parts of the States, we fitted the experimental car with a snow plough and wire brushes. The plough shears were supported by a balanced frame underneath the front platform of the car. These shears could be raised and lowered by foot pressure. Behind the plough shears and just ahead of the front wheels of the car were brushes made of steel wire, and these were kept scraping over the rails by their own weight. The plough served the purpose of removing the bulk of the snow, and the brushes swept the rails and grooves clean in front of the wheel flanges. One day when it snowed very hard, and when the rails were covered about a quarter of an inch deep, we ran the car out upon the experimental track, using in the first instance merely the wire brushes and a little sand on the steepest gradient. It took 2 minutes and 8 seconds to run once round the track, which was soon cleared of snow, taking a mean current of 50 amperes. Snow fell hard all the time, yet it required only 35 minutes to make 20 successive trips, with an average of 30 amperes. In the course of four hours the snow was nearly 2 inches deep, when the car was again started. The brushes alone were of no avail, and the snow plough had to be applied. The first journey was made in 2 minutes and 20 seconds, but with the enormous expenditure of 80 amperes; each succeeding trip, however, took less time and energy, until it reached nearly to its normal value corresponding to clean rails. This would show that with proper appliances, and with cars rapidily scceeding each other, the track can be kept clear; but the accumulation of much snow in the first instance occasions a fearful demand of energy, and without plough and brushes the snow is compressed by the wheels and renders progress almost impossible.

Miles per hour.	Volts.	Amperes.	Electrical h. p.
7.5	404	9.5	5.15
9.3	416	10.4	5.79
9.1	393	10.7	5.40
10.9	434	16.1	9.35
12.4	433	15.4	8.93

Another test on a gradient of 6.58 per cent. rise, one-tenth of a mile in length, gave the following results:—

Miles per hour.	Volts.	Amperes.	Electrical h. p.
2.73	347	27.2	12.65
4.20	403	27.4	13.47
9.30	409	31.3	17.14
6.20	365	32.4	15.85

Recent tests made by a commission on the Frankfurt-Offenbach Electric Tramway, which has been in constant operation for six years, gave the following results:—Two cars, one of which contained the motor, the other an ordinary car attached to it, were taken over the line. The motor car weighed 4 tons, the ordinary car 2 tons, and 20 passengers 1½ tons, giving a total of 7½ tons. Measurements with an amperemeter were made every 5 seconds. The electromotive force varied between 240 and 300 volts. At starting the current used was 80 to 100 amperes, which fell to 40 in 10 seconds, and the mean current on the level road at 8 miles an hour fluctuated between 15 and 25 amperes. On a gradient of 2.85 per cent. 55 to 60 amperes were recorded, and the mean current over a distance of one mile occupying seven minutes was found to be 21.48 amperes, and this included four stoppages. The highest amount of energy recorded at any moment, when starting, was 21,700 watts.

Dr. Louis Bell, in an interesting paper published a few months ago, gave the results of his experiments on the Lafayette road (Ind.), from which I take the above instructive figures. Experimental runs were made on a level road with a car and passengers weighing together 8,200 lbs.

These results are remarkable when compared with those on the level road; considering the steep gradient, one would have expected a much larger consumption of energy at the necessarily low motor speed. On the other hand, the tractive force on the level road appears to be abnormally high at all speeds when the motor efficiency should be at its very best.

More recently Mr. O. T. Crosby published some interesting data concerning three American tramways which, like those of Lafayette, were worked by overhead conductors. The average expenditure of energy on one car on each of the following lines was:—

	Watts.	Electrical h. p.	Load.	Average speed.
Richmond	4,883	6.5	8,500	6 miles
Cleveland....................	4,986	6.6	9,500	9 "
Scranton.....................	5,587	7.4	9,500	5.7 "

The maximum gradients were given to be at Richmond 9 per cent.; at Cleveland "very slight;" and at Scranton 7 per cent., involving maximum expenditures of power of 25.6 h. p., 15 h. p. and 19.2 h. p. (electrical measurements on cars) respectively.

Dr. E. Hopkinson ascertained the mean tractive force on the Bessbrook-Newry Tramway, and he showed that it amounted to 28.9, 27.4 and 37.1 lbs. per ton of gross load hauled during three journeys. The increase in the third journey is due to the mean speed having been nearly doubled. The gradients are not severe in this case, but continuous in one direction.

From numerous sources at our disposal we find that the mean tractive force may be anything from 30 to 50 lbs. per ton, and that it is seldom, if ever, below 20 lbs. on level roads excepting under very favorable circumstances.

All these figures point to the fact that the mechanical resistances on existing tramways are very great, and that even a slight reduction at a comparatively small cost would bring about a considerable saving in traction expenses. By reducing these resistances we not only save power with existing appliances, but by virtue of a smaller demand of tractive force we are enabled to utilize lighter motors, lighter gearing, lighter storage batteries, which, in their turn, again require less for their own propulsion, until a practical limit is reached.

Assuming, *a priori*, high efficiency in electric motors and gearing, improvements as regards mechanical resistance on tramways may be looked for, and, I hope, attempted in the following points:

1. Solid, well fixed, parallel rails.
2. Perfect cylindrical wheels, with thin flanges, or some of them without flanges.
3. Clean rails. The grooves may be swept and watered several times a day by a vehicle especially fitted for this purpose.
4. Sufficient flexibility in axle boxes to allow of free movement in curves.
5. A reasonable number of graduations in the motive power regulated by a switch.
6. Skilful driving, which should occasionally be proved by careful tests and power curves.
7. Automatic sand boxes on steep gradients where the natural adhesion is insufficient.

In conclusion I will repeat that a frequent and judicious use of the ammeter on electric cars will amply repay you for the trouble; it will be the means of great improvements, in the same manner as the indicator diagram enabled us to study the nature of steam engines, and which has been the most direct means of effecting great economy in working.

COST OF A MUNICIPAL PLANT FOR MILWAUKEE, WIS.

The estimate of probable cost of an electric light plant (to be operated on municipal account by the city of Milwaukee, Wis.), as returned by the Board of Public Works in response to a resolution of Common Council, is as follows—the figures being based on a plant capable of maintaining 1,745 lamps of 2,000 candle-power each: 1,745 lamps, $47,115; 70,500 feet of conduit, $70,500; 6,393 poles. $22,375; 8,021 cross-arms, $1,764.62; 1,941 break-arms, $970.50; 18,000 wood pins, $540; 15,424 bolts, $462.72; 18,000 insulators, $1,440; 460 miles of wire, $84,000; 53 miles guy wire, $636; 257,650 feet of rope, $3,145.89; 5,331 pulley blocks, $2,398.95; 150 dozen lamp cleats, $375; setting poles, $6,393; cables in river crossings, $20,000; incidentals, $5,000; tools, $1,000; real estate, $20,000; buildings, $20,000; four 500 horse-power engines, $60,000; 14 boilers, $21,000; shafting, etc., $20,000; 55 dynamos, $55,000; 55 lightning arresters, apparatus, etc., $5,000; incidentals, $5,000; tools, $500; total, $575,442.18.

Mr. E. R. Weeks, the late president of the National Electric Light Association, is on a visit in the East on business and pleasure.

THE APPLICATION OF ELECTRICITY TO AGRICULTURE.[1]

BY N. SPECNEW.

ELECTRICITY has already been applied to numerous commercial purposes, and in this article I propose to study its influence on plants and its application to agricultural purposes. Ever since electricity has been a science its effect on the growth of plants has been the object of much research. The early investigations, however, resulted in contradictory results, which may be explained by the then imperfect state of electrical science, and by the embryonic conditions of its technical applications. It was owing to this state of affairs that Jolabert, Nollet, Mainbray, Achard, Berthollon, and Pardini Van-Marum, affirmed that electricity favored the development of seeds and accelerated the growth of plants; whilst Ingenhouse, Van Tootswyck, Sylvestre, Senebier, and, to some extent, Decandolle, categorically denied the influence of electricity. The experiments of the *savants* were evidently inexact, and were carried out in a too limited manner; though, on examining them more closely, we find manifest indications of the influence of electricity. Gradually, however, scientific investigations established in a definite manner the incontestable fact that electricity had a beneficial effect on vegetation. To this result the works of Sir Humphry Davy, Bischoff, Humboldt, Wollaston, and especially Becquerel, largely contributed. But these scientists only occupied themselves with the theoretical side of the question; and it is only since 1845 that the first practical experiments in electro-culture have been undertaken. At this date, side-by-side with barren attempts to utilize gigantic electro-static machines, as suggested by Williamson, we hear of the application of a current of electricity produced by two metallic plates, one of zinc and one of copper, placed in the soil, and united by a wire. This method was first employed in England in 1846 by Sheppard, then by Foster in Scotland, and in 1847 Hubeck in Germany surrounded a whole field with a network of wires. Unfortunately, the results of these experiments were published in terms too vague to be of much use. Sheppard came to the conclusion that his experiments showed that electricity only increased the return from root plants, while grass perished when placed close to the electrode. He also asserted that one-third of the plants which developed were inferior to those which had been under the influence of the electric current. According to Hubeck, seeds developed more rapidly, and buckwheat gave a larger return; but in all other cases the electric current produced no result. At the same date the experiments of Prof. Fife were going on in England, and those of Otto von Ende in Germany. These experiments gave negative results, and even led these scientists to advise the complete abandonment of attempts to apply electricity to agriculture.

After a long interval of time we have the investigations of Fichtner, who employed a battery, the two wires of which were placed in the soil parallel to one another. Between these wires, and parallel to them, peas, grass, and barley were sown, and in every case the crop showed an increase of from 13 to 27 per cent. when compared with the ordinary methods of cultivation.

These experiments, and a number of others, led me to investigate the influence of electricity on plants in every state of their development; but I will content myself in this article with describing only those experiments of practical interest.

I. This experiment showed that by submitting different seeds to the action of an electric current their development is rendered more rapid and more complete. I employed in these experiments seeds of haricot beans, sunflowers, winter and spring rye. In every case twelve groups, containing 120 seeds each, were taken and submitted to the action of the current. Twelve exactly similar groups were not submitted to the action of the current, but, with this exception, were treated in identically the same manner. Both lots of seeds were first plunged into water until they swelled. The seeds were then submitted to the action of the current in the following manner: When still wet they were introduced into long glass cylinders open at both ends. Two copper discs were introduced at either end, and were pushed in until they compressed the seeds. Rods attached to these copper discs were connected to the poles of an induction coil. The circuit contained an ammeter, and the current was kept on for one or two minutes; immediately afterwards the seeds were sown. The temperature was kept during the whole time that they were growing at 6° to 8° Réaumur (45° to 50° F.). These experiments were repeated ten times, and the results in the table are most striking. I have also to add that the plants which resulted from the electrified seeds were more developed; their leaves were far larger and their color brighter than in the case of plants resulting from the non-electrified seeds. The current had no effect on the yield.

——	Peas.	Beans.	Barley.	Sun-flowers.
Electrified seeds developed in..	Days. 2.5	Days. 3	Days. 2	Days. 8.5
Non-electrified seeds developed in............	4	6	5	15

II. A second series of experiments was carried out with large plates (.445 metre × .712 metre) of zinc and copper which were placed in the soil at the ends of the plots, the rods connected to their upper faces being united by a wire. This disposition was, therefore, equivalent to a battery (zinc | earth | copper), the current of which passed from one plate to the other through the ground. This method was applied more especially to pot herbs and flowering plants. The experiments were carried out at the Botanical Gardens at Kief. The influence of the current was manifested by a larger crop and by the growth of vegetables of enormous dimensions.

III. In a third series of experiments the idea was to apply electricity on a large scale, and current electricity was replaced by static electricity. These experiments were carried out on a site situated in the government of Pskow. In order to understand them better, it is necessary to remember the effect which has been established by experiments, viz., that the slow discharge of static electricity facilitates the assimilation of nitrogen by plants. It is for this reason that plants which are grown in a Faraday metallic cage contain 50 per cent. less organic matter than the plants which are grown in the open air.

On the different plots of earth sown with different seeds (see table below) we placed insulating rods, at the top of which were placed collectors, shaped like crowns. All these collectors were united by means of wires. Atmospheric electricity was thus collected above the seeds, and they matured in the midst of a highly electrified atmosphere. The results of this form of electro-culture are shown in the table. The figures give the averages of five years. All the plots between which comparisons are made were under identical conditions. These figures show, indisputably, that there is a considerable increase in the yield, whether of seed or straw; it was also observed that ripening was more rapid, especially for barley, which, in many instances, ripened twelve days sooner with electro-culture. Another important phenomenon was also observed. Potatoes were seldom diseased when grown by electro-culture; instead of 10 to 40 per cent. of them being bad, only 0 to 5 per cent. were so. These properties of electricity deserve all the more attention, since there are experiments which prove the beneficial effects of electricity on vines attacked by phylloxera. The enormous importance of these facts is self-evident; they seem to offer a new means of combating the microscopic diseases which attack vegetable growth.

A very practical question is—how much does electro-culture cost? I am only able to give the cost of experiments undertaken by myself. The cost of the two metallic plates in Experiment II. is about $4. The installation of these plates does not require much time nor much technical knowledge, and it must be remembered that once *in situ* the plates are good for several years. The electro-static experiment No. III. was more costly, since it was necessary to have from 50 to 60 insulated rods per dessatin (2 acres). Each collector costs about $2. But in this case also the expense once incurred the installation lasts for some time. I trust these experiments will be repeated on a still larger scale, and that some day we shall see electro-culture assume large proportions.

Plants.	Quantity of seed sown, in funts.	Mode of culture.	Crop per dessatin.		Percentage gain due to electro-culture.		
			Seed in funts.	Straw in funts.	Seed vol-ume.	Seed weight.	Straw weight.

[1] *La Lumière Electrique.*

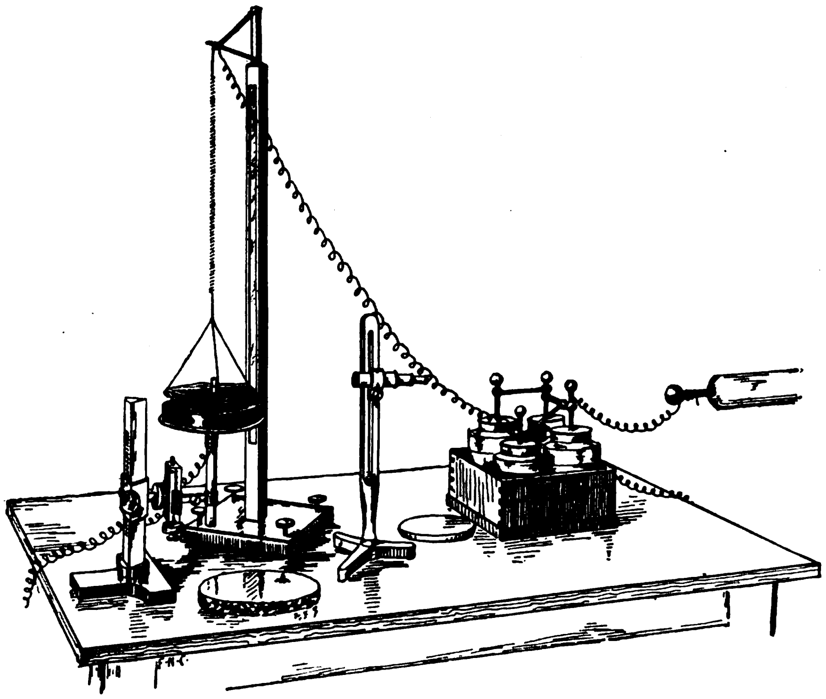
ON A LARGE SPRING-BALANCE ELECTROMETER FOR MEASURING (BEFORE AN AUDIENCE) SPECIFIC INDUCTIVE CAPACITIES AND POTENTIALS.[1]

BY PROF. ALFRED M. MAYER.

THIS apparatus was devised by me for showing to my classes the general phenomena of induction through various dielectrics, and for making approximate measures of their specific inductive capacities. These phenomena and measurements are rarely shown to students, and when their exhibition is attempted the actions on the apparatus used are generally too minute to be seen by a class, and hence the measures deduced from these actions are unsatisfactory.

The apparatus here described has done excellent service during five courses of lectures. Its chief characteristic is that it shows *directly*, and not inferentially, that different dielectrics transmit the force of electricity in different degrees.

The engraving gives a general view of the apparatus. A helical spring, made of brass wire of .012 in. diameter and with 800 turns, is supported by a bracket formed of rods of glass. These rods were dried by heating in a gas-flame and while hot were coated with paraffin. To the lower end of the spring is suspended a disc of thin mica 16½ cms. in diameter, silvered on its upper and lower surfaces in a silvering solution. This disc, which was nearly flat, was made rigid and as nearly flat as possible, by cementing (under pressure) to its upper surface nine light and straight rye straws. Six of these formed chords of 60°, the other three formed an equilateral triangle included by the hexagon. This prevents flexure of the plate when it is suspended at three points by the fine wires shown in the figure. This silvered disc is surrounded by a guard-ring supported on three paraffined glass rods. The ring and rods are not shown in the figure.



LARGE SPRING BALANCE ELECTROMETER.

Under the silvered disc and parallel to it is a brass plate connected with the earth, and movable up and down by means of a rack and pinion and a micrometer-screw. In ordinary work before a class the micrometer-screw is not required. The *difference* only between the distances of the earth-plate from the mica-disc is required in the measurement of specific inductive capacity, and this difference can be measured accurately enough by means of a millimetre scale cut on the column of the support of the earth-plate.

A tube of thin glass is cemented at the centre of the top of the mica-disc. On this tube is pasted a piece of paper with a fine line drawn on it parallel to the disc. Through the telescope on the right we sight on a horizontal thread this line, and when the apparatus is charged we can then always depress the mica-plate to the same level, and with the same force, by gradually raising the earth-plate.

The helical spring is connected with the Leyden battery, which latter is charged with + electricity from an electrical machine. To insure a constant charge during the two measures required to determine a specific inductive capacity, a simple torsion-balance carrying a gilded pith-ball is repelled by a similar ball at the end of a rod connected with the battery. A pointer on the torsion-rod moves over a graduated arc.

To show the general phenomena of the action of a dielectric compared with air, we charge the apparatus and bring up the earth-plate till the mica-disc is sensibly depressed by the attraction existing between it and the plate connected with earth. The disc of the dielectric is now slid on the earth-plate, when every one sees a considerable depression of the mica-disc by the increased force between the two plates through the intervention of the dielectric. Or, we may reverse the operation, and first place a dielectric on the earth-plate, then slowly raise this plate, with the dielectric, till the attraction between earth-plate and disc has caused the latter to be depressed so far that it is just above the point from which it would descend to *contact* with the dielectric. Now suddenly slide the dielectric from the earth-plate. The disc at once rises through a considerable distance, which is distinctly visible throughout the lecture-room. In the case of a glass disc 2 cms. thick this upward motion may amount to 3 cms., and after a few oscillations the mica disc comes to rest at a distance of about 1½ cm. above its previous level.

To show the "electric absorption," "residual charge," "permeability," or "dielectric afterworking" (Boltzmann) of a dielectric we use a disc of parafin. With this on the apparatus we raise the earth-plate till the mica-disc is sensibly attracted, and is stationary. This condition, however, only lasts for a short time. Soon the disc begins to descend, and after a minute or two has come near the paraffin, to whose surface it now rushes. It cannot now be detached till the battery has been discharged, or the earth-plate has been lowered so much as to unduly stretch the spring.

This experiment presents clearly a fact long known, that, with the exception of sulphur, all dielectrics, and especially paraffin are "permeated," or "polarized." in the condenser by time-action of induction, and so is increased the attraction existing between the plates. Boltzmann[2] shows from his experiments that with times of inductive action lasting $\frac{1}{360}$ to $\frac{1}{64}$ sec., $\frac{9}{10}$ sec., $1\frac{3}{10}$ sec., and 45 secs., the specific inductive capacity of paraffin is respectively 2.32, 2.51, 2.56, and 8.12. Schiller's[3] experiments show that for times of charging plate-glass in the condenser of $\frac{1}{20000}$ and $\frac{1}{25}$ sec., the specific inductive capacity is respectively 5.83 and 6.34, or an increase of 9 per cent. in .03995 of a second. Wüllner[4] gives these conclusions from his experiments on the subject: "The instantaneous capacity (that is, the capacity when the charging lasts for a very small fraction of a second) is of quite a different nature to that capacity which increases slowly as the electrification continues. The 'instantaneous capacity' is independent of the conductivity—the 'slow capacity' is not."

To measure the specific inductive capacity of a substance, we place the guard-ring around the mica-disc. This ring has projecting from the edge of its circular opening three short fine wires, so adjusted that when the mica-disc rests on these wires the lower surfaces of disc and guard-ring are in the same plane. The apparatus having been charged, the dielectric is introduced and the earth-plate is raised till the mica-disc is attracted so that it rests on the three wires of guard-ring. The plate is now very slowly lowered till the tension of the spring just exceeds the attraction of the plates, when the disc suddenly rises. The scale reading on the support of the earth-plate or of the micrometer-screw is read. The dielectric is now removed and the disc brought down on the wires by raising the earth-plate, and then by lowering this plate the disc again leaves the wires, and the corresponding scale reading is taken. From the *difference* of the scale readings the specific inductive capacity is determined, as follows:

---

[1] *American Journal of Science.*

[2] *Wiener Sitzungsber.* Bd. lxviii, 1873.

[3] *Pogg. Ann.*, 152, 1874.

[4] *Sitzungsb. königl. bayer. Akad.*, 1877.

Let the scale reading when only air is between the plates be s; when the dielectric is introduced, s_1; then $s-s_1$ is the distance the earth-plate has been moved so as to give in the two experiments the same force of attraction on the mica-disc. A dielectric of thickness t and specific inductive capacity K equals in capacity a condenser with a thickness of air between plates equal to $\frac{t}{K}$. Now when we introduce the dielectric plate it replaces a thickness of air, t. So the effect of introducing the dielectric is to increase the electric capacity of the apparatus as if we had brought the earth-plate and the mica-disc nearer by this distance t and then farther apart by the distance $\frac{t}{K}$, which is the same as if we had diminished the distance between the earth-plate and disc by $t - \frac{t}{K}$. But as in the two experiments the force on the mica-disc is equal, we must have caused an equal *decrease* in *capacity* by increasing the distance between earth-plate and disc by the quantity $s_1 - s$, when the dielectric intervened, and this *measured* increase of distance equals the imaginary decrease of distance produced by the dielectric, and we have $t = \frac{t}{K}(s_1 - s)$ and $K = \frac{t}{t-(s_1-s)}$.[5]

We use a disc of sulphur about 2½ cms. thick as the body to experiment on in this measure before a class, as sulphur is very slightly, if at all, affected by time induction during the interval occupied by the measure.

If the guard-plate be removed the phenomena become more apparent to the audience, but the measure is not so exact. In making measures without the guard-plate we use the telescope and the line on the glass tube, or, for ordinary qualitative illustration, a pointer may replace these.

It need hardly be stated that measurements with this apparatus are of little value when compared with the measures made with the excellent apparatus of Gordon where entire control of the time of charging, and means of measuring, very minute differences of capacity are used. Nevertheless the measures obtained with this apparatus are really more reliable than those obtained by some of the older experiments. The exhibition of the actions of this apparatus, however, are well worthy of being shown to students. The clear ideas and lasting impressions they give, from their directness and easy comprehension, will reward the teacher for the time he may give to the construction and use of the apparatus.

The same instrument will also measure potential, for it is really a huge and rough absolute electrometer. Certain precautions are, however, needed in its use in such measures. In the formulæ used in measurements with the absolute electrometer,

$$V = D\sqrt{\frac{8\pi W.g}{A}}; \text{ or } V - V' = (D-D')\sqrt{\frac{8\pi\ W.g}{A}},$$

one might suppose that W could be determined for the spring-balance electrometer by merely adding the weight in grams required to depress the silvered disc down to the level of the guard-plate; but, on electrifying the helical spring, its coils separate by mutual repulsion and a certain lengthening of the spring results. This action may be determined and allowed for by first ascertaining the weight of mica-disc and its wires and additional weight required to depress the disc to contact with the wires of the guard-plate. The disc is now detached from the spring and placed on the guard-plate wires. On the top of the disc is a tube, in electrical connection with the disc, and containing mercury. The earth-plate is at the position it has when we are measuring potential. The spring is so stretched by a weight that the straight end of its wire dips into the mercury in the tube on the mica-disc, and the apparatus is charged to the same potential it has when we are making a measure of that potential. We now ascertain the weight required to stretch the spring to the same extent it was stretched in the previous experiment. The difference in weight required in the two experiments gives the repulsive action of the electricity on the spring. This correction, however, is not precise, for the wire at the end of the spring is slightly pushed upward by the mutual action of the electrified wire and mercury.

Stevens Institute of Technology, Hoboken, N. J.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

A PIONEER ELECTRIC RAILWAY PATENT.

[128]—In Kapp's "Electrical Transmission of Energy," revised edition, under the head of the Evolution of the Electric Railway, reference is repeated to the patent granted to Henry Pinkus in the year 1840, by the United States Patent Office. This is an error. Mr. Kapp is very good to credit an American with the origin of the idea, but it seems to belong to an Englishman. The passage should read "British" instead of the United States Patent Office.

Some of the readers of THE ELECTRICAL ENGINEER, may be interested to know the electrical details of those patents. In March, 1884, Henry Pinkus was allowed a patent in England for a "Railway System." One of the forms consisted of a closed conduit between the rails. Within the conduit a piston traveled under the influence of an air exhausting pump driven by a stationary steam engine. The traveling piston carried permanent magnets within the sealed conduit, which were intended to attract other magnets carried on the car on the surface. This is the earliest reference to the use of magnetism in any mechanical form recorded in the British Patent Office.

The next reference is in June, 1887, when Thomas Davenport, one of our own countrymen, patented in England an electric motor. In November, 1839, William Taylor patented an improved electric motor. In September, 1840, Henry Pinkus patented improvements in "Pneumatic Railway Propulsion." Among his many suggestions is one in which electric batteries are placed in wells or tanks below the surface. Sectional conductors leading therefrom are exposed between the tracks and a traveling contact is maintained between the stationary batteries and an auxiliary electric motor, which is carried on the steam locomotive. The object of this auxiliary electric motor was to enable the superintendent at a distant point to blow the whistle, apply the brakes or shut off steam by interrupting the current. The troublesome part comes in where in this patent Pinkus incidentally suggests that "Taylor's rotary wheel" or any other electro-magnetic engine may be used as the moving power on a locomotive engine by taking up the electric force from the wires laid down between the rails.

JNO. C. HENRY.

New York City.

STEAM VS. ELECTRIC LOCOMOTIVES.

[129.]—Some time ago I read with interest Dr. Louis Bell's excellent paper on steam traction as compared with electrical traction, and consider it one of the fairest articles on the subject yet published. In the issue of THE ELECTRICAL ENGINEER for May 14, Mr. John C. Henry endeavors to prove this excellent paper erroneous, with but little success, however, where the reader of his article has any knowledge of locomotive construction and performance.

Mr. Henry's paper is very fair in one thing and in one only, and that is, his figures of coal consumption. While having no reliable data at hand I should be satisfied to accept his coal figures in preference to Dr. Bell's as an *average* consumption, though not doubting that Dr. Bell may be right under favorable circumstances; but I wish his figures might have been taken from some standard engine or the English compound on the Pennsylvania R. R. instead of that engineering monstrosity, the Strong locomotive.

The rest of Mr. Henry's article in regard to the locomotive seems to me to be based on an entirely erroneous conception. No one attempts to compare the locomotive and the stationary engine where the question of economy is concerned, for their conditions are so entirely different as to make comparison a farce.

The stationary engine is bedded on a solid foundation of masonry, well housed, free from dirt and flying sand, with abundant steam supply and in perfect alignment, which materially reduce friction of moving parts. The locomotive on the other hand frequently has an uneven track for a bed, its working parts exposed to rain and sand, and very often has to "run for steam," that is, favor the fire at the expense of economy. Again, it is hardly ever in the same alignment for two consecutive minutes, being varied as the drivers roll over frogs, rail joints or similar depressions or obstructions; and yet, notwithstanding these unfavorable conditions, is often run at a piston speed exceeding the best of stationary engines. As an example we may take the "Bound Brook's" 89.6 miles in 85 minutes.

While there is no comparison in the economy of the two it is hardly fair to misstate so many points concerning the "living monuments to nameless thousands of students." To deal with the subject properly the locomotive's cut-off does not depend on manual operation, any more than does that of the stationary engine, but upon the eccentric. The only difference is that the engineer is the locomotive's governor instead of the ball or fly-wheel governor of the stationary engine, and the only manual work is in *changing* the cut-off to suit conditions. The cut-off is just as automatic as in any stationary engine, being performed by valve gear in much the same manner as the Porter-Allen stationary engine. I wish it understood that I am speaking of the standard link valve gear of railroad use to-day, and not any of the grasshopper affairs that save 116 per cent. of fuel every day.

Locomotive valves are not of necessity *slide* valves, nor are they necessarily on top of the cylinder, "owing to peculiar construction;" if Mr. Henry will call on me I shall be pleased to show him drawings of many foreign engines, as well as domestic ones of older date, with valves on the side as well as on the bottom. Nor are *slides* necessary; the Baldwin compound engine, now on the B. & O. R. R. has piston valves. As for having "full weight of steam pressure against their movement," nothing could be more incorrect; all standard engines, or nine-tenths at least, have balanced valves equal to any stationary valve.

The locomotive boiler probably does not give the most economical results, but when such concerns as the Calumet and Hecla Mining Co. use that type for stationary work, it gives the impression that there are worse boilers made.

The balancing question is the last that needs some correcting, and here is another glaring error, for the Baldwin Locomotive Works always test their engines by jacking up the frame and running the drivers in air and then balance to run steadily. Mr. Cloud (not McLoud) of the Pennsylvania R. R. did investigate the "hammer blow" question and found an *apparent* blow of 9 tons instead of 60 as Mr. Henry states, but this question is not considered by the majority of railroad men to amount to very much in practice; surely not when a locomotive is perfectly balanced, though perhaps very few are perfect.

No one denies that the rotary motion of the electric motor is to be preferred to the reciprocating motion of any steam engine, locomotive or stationary, and no one is more friendly to its adoption wherever practical, than the writer. But what is objectionable is the continued misstatement regarding steam engines and the unwarranted claims that so many make for the electric motor and similar appliances. Such statements not only cause the steam engines to be underestimated, but any one familiar with steam is apt to distrust the writer and his cause as well, who makes such bold assertions. There is nothing gained by claiming everything; it savors too much of the patent medicine advertisements, and gains no friends.

Another point against electric motors, for trunk railway service, is their first cost. Supposing the cost of running and maintenance the same, it is much higher than that of steam locomotives of the same power, and this alone would debar them, other conditions being equal.

The *Railway Review* for May 31, has a very good editorial on this subject which all interested might read with profit, for one can learn much from the criticisms of others.[1]

That electricity is destined to play an important part in many of our great enterprises, there is no doubt, and none will welcome it more than I, but sometimes its enthusiastic friends do it more harm than good, and it is to promote a spirit of fairness that prompts this communication. Acknowledging the enemy's good points and then setting to work to excel them, is the best and safest way to progress.

Philadelphia, Pa.

CORRESPONDENCE.

BOSTON.

Bell Telephone Dividend.—Eastern Electric Cable Dividend.—Boston Has Power to Light City Hall.—Debenture Bond Company.—Judicial Court on Municipal Lighting.—Providence Electric Subways.—Reception to Capt. Meigs.—Meigs Location in Boston.—Charges of Corruption in Legislature on Elevated Railroad Bills.

THE American Bell Telephone Company has declared a regular quarterly dividend of 3 per cent., and an extra of 6 per cent., 9 per cent. in all, payable July 15th to stock of July 1st. The books reopen July 16th.

The Eastern Electric Cable Company has declared a semi-annual dividend of 3 per cent., payable June 16th.

The Corporation Counsel has reported to the City Council that in his opinion the city of Boston has the power to make or provide electric light to furnish light for the City Hall, the Court House and the Registry of Deeds.

It is reported that Messrs. Kidder, Peabody & Company have decided not to interest themselves in the proposed Thomson-Houston Debenture Bond Company, but Messrs. Lee, Higginson & Company will go on with the formation of the company alone. The deposits of the common stock have reached about 173,000 shares out of a total of 180,000.

The justices of the Supreme Judicial Court sent to the house last week, a communication which was read by the clerk, expressing their desire to be excused from giving an opinion on the order adopted May 27, as to whether cities and towns have the right under existing laws to manufacture gas or electric light for use in the public streets and buildings, or for sale to the citizens of such cities and towns. In making this request the court believes the occasion has not arisen contemplated by the constitution in which its opinion may properly be recognized, since the question proposed affects only the construction of existing statutes which the legislature can amend or repeal as it sees fit.

The Mayor of Providence has vetoed the bill authorizing the electric light company to build an electric subway for electric light and power wires. This complicates the overhead question again, and it may be some time before the electric light company can be induced to make any more overtures towards burying their wires.

Captain J. V. Meigs, was tendered a reception at the Board of Trade rooms, in Lowell, Mass., by a number of his friends, in honor of the passage of the bill by the Legislature, granting him a charter for his elevated railroad system in Boston. In returning thanks for the reception Captain Meigs stated that he believed there would be no difficulty in getting money to construct the road. The Meigs' Elevated Railroad Corporation has applied to the Boston Board of Aldermen for locations from Sullivan Square, Charlestown, to Jamaica Plain, and for stations along the route.

A cyclone has struck the Legislature committee on elevated railroad bills, in the shape of charges by Mr. Williams, of Dedham, as to improper methods having been used in connection with the passage of the West End bill. A special committee has been appointed and a sweeping investigation is being made, the West End and Mack bills being tabled meanwhile.

The Senate has sent to the next general Court, the house bill authorizing cities and towns to supply themselves with gas and electricity.

BOSTON, June 14, 1890.

PITTSBURG.

Electric Railway Work—The New Telephone Exchange—A Successful Local Company.

The rumor is once more current in the local press that the Pittsburg and Manchester and the Pleasant Valley Electric Railway Companies are about to consolidate. These two corporations control the entire street car lines of Allegheny City, and their consolidation would create a very profitable monopoly of all the street car travel in the "City of Parks."

The Duquesne Traction Company has secured the location of its power house and ground will be broken for the erection of the structure within a few days.

The anti-induction telephone appliance to counteract the noise of the streets and thus make the telephone more powerful has for the first time been introduced in this city at the Eleventh ward police station.

The Johnstown Electric Street Railway Company is laying a double track on Main street, Johnstown, Pa., and expects to have electric cars running thereon not later than the first of next July.

The gas committee of Allegheny City met on the evening of June 11 and the curious fact developed that the contracts for lighting the city did not include the electric building itself. Then the fathers of the city wagged their heads in affected wisdom and ordered the superintendent to have the building wired for lights.

The Central District Telephone Company, which has for years complained of being greatly cramped for room in its present quarters in the First National Bank building, has at last found a new location. The company concluded the purchase of a very handsome piece of property on Seventh avenue a few days ago, and it is the intention to erect a magnificent seven story building on the acquired site.

The Citizens' Electric Light Company, of Braddock, illustrates its successful career by the announcement that it will shortly erect a new electric light station, which is to be the finest in Western Pennsylvania. When the building is finished the company will also add two more boilers, one 125 h. p. engine, a 50 light arc dynamo and a 750 light incandescent machine. The Westinghouse alternate current apparatus is being operated in this plant.

PITTSBURG, June 14, 1890.

MR. GUIDO PANTELEONI, the general Western representative of the Westinghouse Electric Co., has closed contracts for Westinghouse Electric Railway equipments at Springfield, Mo., and Pittsburg, Kan.

REPORTS OF COMPANIES.

WESTERN UNION QUARTERLY STATEMENT.

The statement of the Western Union Telegraph Company for the quarter ending June 30 shows:—Net earnings, $1,750,000; increase, $300,000. Surplus April 1, $9,590,916; increase, $1,193,718. Total, $11,340,916; increase, $1,493,718. Interest and sinking fund, $243,143; increase, $33,143. Balance, $11,097,773; increase, $1,360,575. Dividend, 1¼%, $1,077,382. Surplus, $10,020,377; increase, $1,460,561.

ANNUAL MEETING OF ERIE TELEPHONE.

The annual meeting of the stockholders of the Erie Telegraph and Telephone Company was held in New York on June 11, and the old board of directors were chosen, as follows: Abner S. Adams, Charles E. Adams, Charles J. Glidden, Francis Jewett, J. W. C. Pickering, Levi Sprague and Asa C. Russell, of Lowell, Mass.; Wesley A. Gove, of East Boston; W. J. McKinnie, of Cleveland, O.; James A. Weston, of Manchester, N. H.; Harvey A. Whiting, of Wilton, N. H. The directors organized by the choice of Levi Sprague, president; Charles J. Glidden, secretary and treasurer, and J. P. McKinstry, general manager. At the annual meeting of the Southwestern Telegraph and Telephone Company the same officers were elected, with the exception of Mr. McKinnie, and in addition John E. Hudson and Gen. Thomas Sherwin as directors, the latter representing the interests of the American Bell Telephone Company.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

In accordance with an agreement between the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, the headquarters of the Institute will be hereafter at the House of the Mechanical Engineers, 12 West 31st street, near Fifth avenue. Communications and exchanges should be addressed accordingly. The Secretary's office will be in the front room on the third floor. The joint library and reading room on the second floor. The auditorium, in which the meetings of the Institute in this city are to be held hereafter, is on the first floor. The entire premises are being renovated, and during June the Secretary's office will be temporarily located on the second floor.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

The annual convention of this great engineering body will be held at Cresson, Pa., a beautiful resort up among the mountains, on the Pennsylvania Railroad, 102 miles east of Pittsburgh. The hotel rate will be $3 per day. The convention begins on June 26, and will last several days. President W. P. Shinn will deliver an annual address, and a large number of professional papers will be read.

LEGAL NOTES.

THE KEMMLER CASE.

A special dispatch from Albany says: "The next legal step that will be taken by the Westinghouse Electric Company to prevent the use of their dynamos for the execution of murderers in this State will be in the form of a writ of replevin to repossess themselves of the three dynamos of their patent now in the State prisons at Auburn, Dannemora and Sing Sing, which Harold P. Brown, the electrical expert, purchased for the State. The Westinghouse Company claim to retain proprietary interest in the dynamos they sell (or claim merely to lease) to customers, after the manner of the Bell Telephone Company in leasing telephones, and will seek by action to restrain the State from employing them for purposes of execution by claiming that Brown illegally and fraudulently obtained possession of them by collusion with its customers having a leasehold possession of the dynamos in question."

DOUBLE CARBON LAMPS.—BRUSH ELECTRIC CO. *vs.* THE SPERRY ELECTRIC COMPANY. IN CHANCERY.

In the Circuit Court of the United States for the Northern District of Illinois.

Present: Hon. WALTER Q. GRESHAM, Circuit Judge, and Hon. HENRY W. BLODGETT, District Judge.

THIS cause having been brought to a hearing upon the motion of the complainant upon the bill and affidavits for a preliminary injunction to restrain the defendants, the Sperry Electric Company, from infringing complainant's letters patent, No. 219,208, granted to Charles F. Brush, September 2, 1879, and assigned to complainant, by making, using or selling double carbon lamps embodying the invention or inventions of said patent, and having been argued by H. A. Seymour, for complainant, and F. W. Parker, for defendant, and the same having been duly considered, the court finds as follows, to wit:

1. That the double carbon lamps manufactured by the defendants, the Sperry Electric Company, and produced before the Court, viz: Ex. 1, marked "Complainant's Exhibit, New Sperry Double Carbon Lamp," wherein the two pairs of carbons are independently actuated and adjusted and burned successively, the feeding carbon of one pair having a supplemental clamp or device whereby it may be manually latched up and retained, separated from its mate during the burning of the other pair, the latched-up carbon being then automatically released, and the arc established and maintained between the second pair of carbons until consumed; the other lamp, the construction of which is shown in defendant's drawings numbered 7 and 8, and wherein the two pairs of carbons are independently actuated and controlled, and burned successively, and in which the feeding carbon of the idle pair is required to be manually latched up, to insure such successive burning of the two pairs—each embody the invention of Charles F. Brush, as described in said Letters Patent No. 219,208, and specified in the first six claims thereof, and that the complainant is entitled to an injunction as prayed for, restraining the defendant company from manufacturing, selling or using either of such infringing lamps until the final hearing of this cause.

It is therefore ordered, adjudged and decreed, that the defendant, The Sperry Electric Company, its officers, agents, attorneys and employees, be, and they are hereby enjoined until the final hearing of this cause, from directly or indirectly making, selling, offering for sale, or using any double carbon lamps, like or similar to those mentioned in the finding above set forth, or any arc electric lamps in which two or more pairs of carbons are independently adjusted and regulated, and are burned successively to secure the continuous burning of one pair of carbons prior to the establishment of the arc between the other pair, substantially as set forth and claimed in the first claim of Letters Patent, No. 219,208, and also from making, using or selling any electric arc lamps containing the inventions set forth and claimed in the Second, Third, Fourth, Fifth and Sixth Claims, or any of said Claims in said Patent No. 219,208, this order and decree to take effect on and after July 3d, 1890.

W. Q. GRESHAM, H. W. BLODGETT,
District Judge.

INVENTORS' RECORD.

Patents issued June 10, 1890.

Alarms and Signals:—*Electric Annunciator*, J. D. Bishop, 429,599. *Electric Burglar Alarm*, H. C. Shubert, 429,817. *Water Indicator for Boilers*, J. J. Campbell, 429,997.

Conductors, Conduits and Insulators:—*Cable Terminal*, J. C. Reilly, 429,815. *Pipe*, J. P. Culver, 429,844. *Underground Electric Conduit*, H. Flad, 430,010. *Method of Making Glass-Lined Pipe Fittings*, D. Rylands, J. Crowder and R. Morant, 430,041.

Distribution:—*System of Electrical Distribution*, E. M. Bentley, 430,060.

Dynamos and Motors:—*Generator for Electrically-Reciprocated Tools*, H. N. Marvin, 429,729 and 429,732. *Electric Drill System*, H. N. Marvin, 429,730 and 429,731. *Dynamo Electric Machine*, R. Pfund, 429,736. *Electric Regulator*, E. Wagemann, 429,825. *Machine for Turning Dynamo Commutators*, H. G. McLean, 429,946.

Galvanic Batteries:—*Galvanic Battery*, J. Beattie, Jr., 429,596. *Galvanic Battery*, J. Silicio, Jr., 429,708. *Galvanic Battery*, G. H. Felt, 429,895. *Electrode for Galvanic Batteries*, G. H. Felt, 429,896. *Porous Cell for Galvanic Batteries*, G. H. Felt, 429,897. *Solution for Galvanic Batteries*, G. H. Felt, 429,898. *Galvanic Battery*, C. A. Hitchcock, 430,075.

Lamps and Appurtenances:—*Manufacture of Incandescent Electric Lamps*, R. N. Dyer, 429,608. *Electric Arc Lamp*, C. Coerper, 429,787.

Measurement:—*Electric Meter*, J. H. Barnard, 429,751. *Galvanometer*, A. E. Colgate, 429,887.

Metallurgical:—*Method of Separating Ores Magnetically*, C. M. Ball, 430,068.

Miscellaneous:—*Lightning Arrester*, O. J. Lodge, 429,727. *Graphophone*, J. H. White, 429,827. *Switch-Board*, J. M. Anderson, 430,054. *Key-Board Self-Playing Attachment*, J. D. Case and C. W. Evans, 430,065. *Electric Piano-Playing*, J. D. Case and C. W. Evans, 430,066. *Automatic Electric Cut-out*, M. Waddell, 430,096.

Railways and Appliances:—*Electric Railway*, R. M. Hunter, 429,687. *Electric Connection*, C. J. Van Depoele, 429,745. *Electric Railway-Motor Truck*, C. J. Van Depoele, 429,746. *Telpher System*, C. J. Van Depoele, 429,747 *Railway Signal System*, L. B. Firman, 429,899. *Electric Railway Conductor System*, C. J. Van Depoele, 429,981. *Wire and Track Cleaner*, J. Bauer, 429,990. *Electric Railway*, R. M. Hunter, 430,025 and 430,076. *Electric Railway Reissues*, W. H. Knight, 11,083 and 11,084.

Secondary Batteries:—*Secondary Battery*, C. Hering, 429,912, 429,913 and 429,914.

Telegraphs:—*Multiplex Telegraphy*, F. J. Patten, 429,735.

Telephones and Apparatus:—*Telephone*, W. Vogel, 429,801.

THE SYSTEM OF THE INTERIOR CONDUIT AND INSULATION COMPANY.

FEW innovations in the electrical field have excited so much interest of late years as the methods and appliances of the Interior Conduit and Insulation Company of this city, as embodied in their system of wiring houses, office buildings, &c. The company have now issued their prospectus, which is not only a publication of considerable literary merit but enters very freely and exhaustively into a discussion of the vital questions involved in insulation.

After a brief review of the development of electrical distribution and of the dangers involved in fire, the pamphlet points out that if all such actions as tend to cause a fire were made instantaneous and were localized, whatever prejudice still remains against electricity would disappear. It then says:—

"Prior to the inauguration of what may be termed the new electric era, electricity was used almost solely for the purpose of transmitting intelligence; the telegraph, the telephone, the fire-alarm, the various signalling systems and kindred applications are examples of such use. In these industries the insulation of the wires has but one function, viz.: That of maintaining an effective service. If the insulation fails, the service fails; no other untoward result follows for the reason that the currents employed are so weak as to be incapable of developing any considerable degree of heat. With the inauguration of the new era involving new applications, as for example, electric lighting, electric motive power, and kindred uses, employing electricity under high pressure and in vast quantity, there was imposed upon insulation an additional duty, viz.: that of protecting life and property. If herein the insulation fails, not only does the service fail, but life and property are at once seriously jeopardized. That this risk is not an imaginary one is abundantly attested by the numerous recorded accidents which have occurred during the past two or three years. That the remedy for these occurrences is not to be found in an improvement in the quality of insulation is equally well attested by the fact that, in spite of all the manifold so-called "perfected insulations," accidents continue to occur. As a matter of fact, the one branch of electrical science which has not advanced in line with the new demands is this safe-guarding of property from contact with the always-possible abnormal heat development in the wires." It has been assumed by some that inasmuch as electricity was inherently safer than other mediums of lighting, the element of danger was practically absent, and by others that the danger could be sufficiently avoided by improvement in the quality of the insulation, hence the evolution of a host of "improved insulations;" many of which doubtless possess great virtue, but unfortunately they all follow one principle, viz: That of affixing the insulation to, or drawing it upon the wire itself. This is the fatal error. The logic of all the relating facts in the art is against such practice. Modern electrical service is nothing more or less than a service for the distribution of heat. True, economical considerations demand, and physical laws permit, that the conductors conveying this heat shall be so arranged and so proportioned as to remain cool, and therefore safe while doing the calculated duty demanded of them. But the proportions and conditions thus pre-arranged and determined to secure safety are peculiarly liable to accidental derangement, thereby imposing a duty for which they were not calculated; in this event the conditions of safety are gone, and heat is at once developed in such proportion and in such place as the extent and the nature of the derangement may determine. It is apparent, therefore, that any system of insulation which aims to secure absolute protection must take cognizance of, and provide against, the effect of this always possible development of heat. Experience has demonstrated that the practice of affixing the insulation to the wires does not do this. All insulations which can be so affixed are of necessity compounded of oils, gums, or other flexible and adhesive materials, all of which are readily affected by heat. Vain efforts have been made to find a new elementary material, or to compound known materials which shall have the multifold property of high insulation, great resistance to heat, extreme flexibility and proof against acids, gas, etc. The great value to the art of an insulation possessing these naturally diverse qualities has been of late years so keenly appreciated as to concentrate the inventive mind on the line of its pursuit to the exclusion of any consideration of other methods of protecting the wires. This is the only explanation of the failure of the inventors to evolve a natural and effective solution of the problem. Necessity has been well said to be "The Mother of Invention," and it was by virtue of the necessities of himself and the numerous friends who depended upon him for advice in such matters that Mr. Edward H. Johnson was led to suggest the total abandonment of the old practice, and the substitution therefor of an enclosing tube, separate from, but forming a channel for conducting wires, continuous throughout their every ramification, thus fully protecting every inch of wire and rendering it accessible for periodic inspection or renewal, and by the same means absolutely confining within the safe limits of a non-inflammable channel the possible heat development.

"The practical efficiency of such a method scarcely needs to be supported by argument or demonstration. Its very simplicity appeals at once and alike to the intelligence of the expert and the layman.

"The elimination of the element of extreme flexibility as an essential requisite of insulation simplifies the problem, and permits of the employment of a variety of materials not at all available in the practice of affixing the insulation to the wires. Thus the door is opened and the inventor now comes forward to provide the requisite perfection of detail. In this respect the industry is extremely fortunate in the chance which has brought to its aid Mr. Edwin T. Greenfield, a man of wider experience in the old method, and therefore more keenly appreciative of its weakness, than any man in this or any other country; to the thoroughness with which Mr. Greenfield has and is doing his work is due the already high perfection of the new method and the guarantee that it will at once afford superlatively the elements of safety, economy, durability and convenience.

"In further pursuance of the conditions of safety, Mr. Johnson has incorporated with the new system a special conductor upon which he has been at work for some years, the function of which is to convert conditions favorable to a prolonged heat presence into conditions of instantaneous action hereinbefore described as a factor of safety. This conductor is so constructed as to convert all defects which may develop in the wires, such, for illustration, as a break, a leak, an imperfect union or other faults common to all systems of energy distribution into that one defect or fault which is pecular to electrical distribution and which is technically known as a "short circuit." This is a fault which develops instantaneously an abnormal concentration of energy and in consequence effects the immediate destruction of the weakest link in the chain which supports the current. Much has been said and written of the device known as the "safety fuse" and rules and regulations enforcing its use are universal. It is introduced as a link in every electrical chain and is designedly made the weakest link therein—hence a "short circuit" simply means the destruction or giving way of this link, thus insuring by the breaking of the chain the total and absolute cessation of the electric current previously supported thereby. This weak link is, of course, located within safe pockets where the somewhat violent results of its disruption are smothered or otherwise rendered abortive.

"Contrary, however, to popular belief this device does not provide absolute protection. Its failure to do so arises from the fact that it is only affected by an overloading of the chain. It is, of course, apparent that a partial break, an imperfect union or a leakage of the current may develop a sufficient degree of heat to effect the ignition of inflammable materials, and yet not sufficiently increase the current strength to overload and fuse the safety link.

"The object of the special conductor herein alluded to is to convert with absolute certainty all defects, whether a break, a leak or other fault into a "short circuit" and the consequent overloading and fusing of the safety link. The effect of a "short circuit" is generally apparent at the point of its occurrence in the form of an instantaneous flash, herein before alluded to as ineffective of much damage becauseof its brief duration. It is possible, however, to have present conditions of extreme inflammability, as for instance gases, inflammable powder, as in a flour mill, lace or other delicate fabrics, or even the insulation of the wires themselves.

"It therefore becomes a matter of considerable importance to safely localize even this flash, and it is obvious that the inclosing tube does this to perfection, in that every inch of the wire is completely encased within the safe confines of its fireproof interior.

"The Interior Conduit and Insulation Company now enters the field with this new method of insulation, and claims that it is able to effect, not partially and imperfectly, but completely and absolutely that safety which is the one essential to the general adoption of electricity. That this claim is not unsupported is attested by the endorsement the system has already received by architects, electricians, fire underwriters, municipal and other authorities interested in the matter of safeguarding property, and the extraordinary rapidity with which it has been accepted by the public."

The pamphlet then takes up the subject of underground work, and deals with the adaptability of the company's safety tubes for underground conduits. We understand that large contracts for this important class of work are now being carried out, one in Detroit by Mr. C. J. Field, for electric lighting, and another in a Western city for the distribution of electric railway feeders. The following passage is of unusual interest;—

"It is confidently believed that the insulation of the tube itself, combined with the means employed to prevent access of moisture and gases, will sufficiently protect the conductors to enable the customary insulation employed on underground cables to be entirely dispensed with. This belief is so strong that large installations are now being made in which the wires are entirely devoid of insulation, other than that afforded by the tube itself. Whether this practice will be found generally satisfactory or not, it is certain that a comparatively light insulation will suffice, and that the costly and cumbersome insulations and lead sheathing heretofore employed will henceforth be wholly unnecessary. The great evil of condensation, so destructive of all wire insulations, and which is at its maximum in metal conduits, is scarcely a factor in these insulating tubes. It is certainly reduced to a minimum, and is thus within the easy reach of the corrective means which are employed in conjunction with the system. The provision for protecting the conduits from moisture and gases, also prevents the accumulation of gases in the manholes, and consequently avoids the dangers of explosion which attend other systems. The absence of metal sheathing of any kind is an important advantage, as in all systems of electrical distribution which are partly aerial and partly underground, lightning is apt to reach the underground from the aerial wires, and is almost certain to pierce the insulation to get at the metal sheathing, for which it has a great affinity.

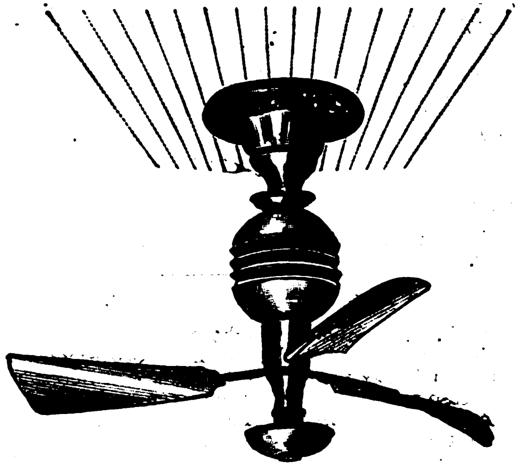
"As the length of cable sections which may be drawn into the ducts, and the consequent frequency of manholes in any conduit is determined by the weight and size of the cables to be drawn in, it becomes a matter of considerable importance to eliminate from the cable all material other than the copper itself, thereby permitting less frequent manholes with a conductor of a given capacity, or the use of conductors of greater capacity with a like number of manholes than is possible with cables employing thick insulations and heavy metallic sheathing.

"Furthermore, if a cable consists only of copper, its withdrawal and substitution by a larger one, does not result in its consignment to "scrap" as in the case of insulated cables. It is in fact just as valuable then as it was originally and may be at once employed in lighter service elswhere; a fact which materially heightens the economic value of the insulated conduits.

"A feature of considerable value is the facility with which a conduit may be given individual ducts of various sizes thus offering greater accommodations for single conductors and small cables than is possible to conduits in which ducts of uniform sizes only are employed."

A FAN, MOTOR AND BATTERY OUTFIT.

The Central Electric Company, of Chicago, are exhibiting a very handsome ventilating fan, the product of the Globe Fan Co., of New York. The fan is entirely of metal, nicely nickeled, light and ornamental in design, and is especially adapted for use in restaurants, saloons, offices and stores. The fan is run in connection with a small motor, and the Edison-Lalande battery and the combination seems to exactly fill a demand that has long existed. The motor can of course be run by the current from an electric light circuit where this is obtainable, but for sick room or residence purposes the battery furnishes the necessary power. The cut herewith illustrates the fan itself. The Central Electric Company has secured the general western agency for this fan and already reports several sales.



THE GLOBE ELECTRIC FAN.

A TELEGRAPH TOURNAMENT IN ST. LOUIS.

Our St. Louis correspondent writes us as follows :—The fast sending tournament of the St. Louis telegraphers, took place last Sunday at Entertainment Hall of the Exposition Building. Each contestant was allowed five minutes, the start being made by a bell signal, and at the end of five minutes the circuit was thrown open by the master clock of the Western Union time service. The prizes were awarded as follows :—

First Class, highest readable speed, first prize $50, to J. M. McAndrews, Postal Telegraph Co., 226 words; second prize $30, to A. O. Ellis, Postal Co., 224 words; third prize $20, to J. C. McIlvane, Western Union, 221 words.

Second Class, highest speed combined with the most perfect Morse; first prize $25, to A. O. Ellis, Postal Co., 224 words; second prize $15, to T. M. Eckert, Western Union, 212 words; third prize $10, F. C. Richie, Associated Press, 210 words.

Third Class, highest readable speed. ladies exclusively, first prize $25, to Miss. Mollie Landrigan, Postal, 206 words; second prize $15, Miss Katie Higgins, Western Union, 202 words; third prize $10, Mrs. Flora A. Potter, Western Union, 191 words.

Fourth Class, old-timers, service prior to 1865, highest readable speed, first prize $25, C. E. Turner 199 words; second prize $15, Mark D. Crane, Western Union, 197 words; third prize $10, James W. Cook, Postal, 179 words.

THE ELECTRIC LIGHT IN THE SUEZ CANAL.

In his last report to the Foreign Office, the British Consul at Port Said gives the following interesting figures with regard to the application of the electric light to vessels navigating the Suez Canal at night. In 1887, 395 steamers used the light; in 1888, the number rose to 1,611, and in 1889, a total of 2,445 vessels navigated the canal with its aid. The average time of transit has been reduced to 22½ hours. The shortest time taken by a steamer in passing through the canal in 1889 with the aid of the light was 14¾ hours.

A NEW METHOD OF COVERING PULLEYS.

In driving all classes of machinery by means of belts, a certain loss of power is always entailed by the slipping of the belt upon the surface of the pulley. This loss becomes a very important consideration in the majority of cases, especially in machinery running at a high speed, and any means of diminishing it in a marked degree is to be hailed by engineer and capitalist as an improvement of marked interest, the merits of which should be immediately looked into, and, if found satisfactory, at once utilized. The latest method of overcoming these losses, and one which appears to present some peculiar and prominent advantages, is now being introduced by the Eureka Cement Company, of Owosso, Mich. Mr. Frank Henderson, of that company, is very busy installing their system in all parts of the country, and introducing it to the notice of those interested in such matters. This system comprises the following points: It consists in the employment of a specially prepared leather covering for the pulley, which is extremely soft and elastic and never glazes by the rubbing action of the belt, as is the case when ordinary leather is employed for this purpose. It is applied to the pulley and held firmly to it for all time by means of a special cement, which is soft and never hardens like ordinary felt cement or glue. No rivets of any kind are employed, but the leather covering is firmly attached to the iron of the pulley by the cement alone. In carrying this out the iron pulley is first subjected to a secret treatment by which means this very desirable result is attained. Heretofore it has been found impossible to effect any lasting contact between leather and iron, the covering invariably working loose from the pulley unless mechanical means, such as rivets, with their accompanying disadvantages and troubles, were employed. By this system it is claimed that 50 per cent. more power can be transmitted, and all slipping is reduced to an imperceptible factor, producing a perfectly even motion, especially desirable in the case of dynamo electric machines. Belts may be run much looser, thereby reducing loss by friction in journals and the liability of hot boxes to a minimum, and causing the machine to run very much more easily. The leather covering is put on so that it is as even and true as though turned in a lathe, and it is estimated that one man can cover at least 50 square feet per day. Once attached, the covering will stand for years, and never loosen or come off except when naturally worn out, the length of time varying with the circumstance and work done. Some pulleys have been covered and the slip absolutely stopped when it amounted to as much as 15 per cent. In other places, where the oil on the belt was so great that the machine had to be laid aside, as it was found impossible to drive it running on an iron pulley, a perfect alleviation of the trouble has been effected. This system is already in operation in some of the finest electrical plants in the country, among which may be mentioned the plant in the Auditorium, Chicago, and the Edison and Brush Companies' stations in Detroit, and is also being used in many other industries. The improvements effected by its use are of such a palpable nature, and the remedy for troubles heretofore existing is so simple, that the matter is one which will be looked into and rapidly adopted by those engaged in the transmission of power by means of belts in the operation of machinery of all kinds.

EDISON'S ELECTRO-MAGNETIC ORE SEPARATION.

Reports from Middletown, N. J., state that the Edison Contracting Company has equipped fine works for operating at the Ogden iron mines, has built houses for its workmen, and laid a spur road from the Susquehanna and Western railroad to the mines. It is said that Mr. S. O. Edison will have charge.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

KERITE WIRES AND CABLES.

Mr. Geo. B. Prescott, Jr., the general agent for Day's Kerite wires and cables, 16 Dey street, has just issued a very tasteful, comprehensive and interesting " Price List," of 40 pages. The introduction in calling attention to the fact that Kerite has been in the market for nearly thirty years, says:—" It is proof against the corrosive elements in earth, air or water; the greatest extremes of heat and cold do not impair its flexibility, firmness or insulating properties. It will endure long-continued heat at 200° F., and, for short intervals, 250° to 300°, and may be safely immersed in boiling water. Acids act upon it very slowly, strong solutions of alkalies do not injure it, and it is less affected by chemical re-agents than any other insulating covering. Gutta-percha in the open air soon becomes brittle, cracks and falls off; with exposure to the sun it softens, then cools, shrinks, cracks, dries and falls off, thus destroying insulation. India rubber, even when vulcanized, only partially escapes these difficulties, while Kerite is subject to none of these objections, and does not, like the preparations of gutta-percha, or vulcanized rubber, contain the elements of its own destruction. Mineral oils, illuminating gas, or the roots of plants do not affect it, and the action of water, salt or fresh, protects it and improves its insulation. The marine borers of southern and tropical seas, which destroy gutta-percha, do not attack it; it is proof against the heat of the tropics, which renders all other insulations useless, and against the ravages of white ants, which destroy gutta-percha. The qualities that render it indestructible by solar heat, or corrosive agents, insure its durability in all climates, and while neither gutta-percha nor vulcanized rubber will bear long storage without great and rapid deterioration, Kerite, under the same conditions, undergoes no change."

A large number of tables are given for all classes of telegraph, telephone and electric light wires and cables, and we notice on page 22 a new table of value for iron wire. Cuts are also given of the various makes.

The concern is reported by Mr. Prescott to be as busy as usual, the factory running to its full capacity on wires, cables, tape, etc. One cable finished a few days ago for the Western Union Co., is half a mile long, and is intended to be laid out West. It is a 5 conductor, each consisting of 3 strands of No. 18, B. W. G., insulated to $\frac{9}{32}$ in. The double armor consists of 30 No. 12 galvanized steel wires, and 14 No. 4 galvanized steel wire outside of that.

THE INTERIOR CONDUIT AND INSULATION COMPANY.

This company, of 16 and 18 Broad street, signalizes its occupation of its handsome new offices on the second floor by issuing in compact and severely elegant form its prospectus, to which extended reference is made in another part of this issue. The officers of the company are E. H. Johnson, President; S. Bergmann, Vice-President; W. A. Willard, Secretary and Treasurer; J. H. McClement, Comptroller; E. T. Greenfield, Electrician. Messrs. Johnson, Bergmann, McClement and Greenfield are directors, with P. H. Klein, H. Steers, C. E. Runk, S. Insull and F. J. Sprague. The entire system and details have been and are being protected by letters patent, which, it is claimed, secure to the company practical immunity from competition. It is not intended, however, to exploit the business in reliance upon patents, but to establish it upon a sound commercial basis, recognizing the force and value of competition precisely as if the patents did not exist. It is the intention of the company to supply the trade at large upon equal terms and solely upon a manufacturing basis, not handicapping the business with royalty charges or excessive profits. The demand is large, and it is intended to supply it at a price which, while netting the stockholders fair profits, will insure satisfaction to its customers and minimize the incentive to infringe the company's patents. To accommodate the rapid growth already achieved, new and enlarged factory facilities have been provided, and the company thereby becomes equipped to promptly and satisfactorily supply the future, as well as the already considerable demand.

JOHNSTON ELECTRIC TRAIN SIGNAL CO.

The Johnston Electric Train Signal Co., of Boston, have purchased a valuable property at Woburn, Mass., which they will occupy and utilize immediately as a factory. The building is four stories in height, has a frontage of about 100 feet, and is upward of 200 feet long. It is located near the railroad, and its facilities are excellent. The Company will set up its machinery at once, and within a month will probably have at least 100 mechanics at work. It is the intention of the Company not only to manufacture the train signal, which is meeting with general approval, but push-buttons of all descriptions, and a number of new specialties in the electric hardware line.

THE TRIUMPH COMPOUND ENGINE.

This new type of engine, which is now becoming well known and highly thought of for its smooth running qualities, its simplicity and the exceedingly small floor space it occupies, would, by this time, have been installed in one of Cincinnati's largest central stations were it not for the molders' strike which is embarrassing so many manufacturers in that vicinity. However, the company expects to be under full swing in the course of a few days, and in the meantime electric light and power men have a splendid opportunity of seeing the sixty horse-power engine running in the works of the company and viewing the construction of a 250 horse-power engine now being built for electric lighting and power purposes.

THE SEBASTIAN-MAY CO.

The works of this company in Cincinnati are not only of interest on account of their completeness and facility of turning out machinery, lathes, etc., promptly, but also because here we find one of the largest, if not the largest, electric motors in Cincinnati. Mr. Sebastian recently told one of the staff of THE ELECTRICAL ENGINEER, who had the pleasure of visiting his works, that heretofore his company had been compelled to content themselves with power furnished through shafting from an adjacent building—a power which was not only inadequate but unreliable. The different electrical people, he said, finally convinced him that a motor was what he wanted and now a twenty horse Queen City electric motor (440 volts) is running the entire factory noiselessly, easily and satisfactorily.

CARD MOTOR AND DYNAMO CO.

Since the reorganization of this company under the able management of Mr. Walter, the facilities of their Cincinnati factory have by no means been adequate to meet the demand for their various sized arc and incandescent motors. It will doubtless be only a short time ere the natural expansion of this company will be able to take care of orders as fast as received.

THE STILWELL AND BIERCE MFG. CO.

This company which is so well known through the large number of Victor turbine wheels it supplies to electric lighting and power plants from year to year where water power is available, is now turning out an unusually large order for the electric light company at Spokane Falls. There will be no fewer than thirteen of its large horizontal turbines side by side in this installation, all running on the same line of shafting. One of the features of this outfit is the very ingenious and effective system of clutches by which the different wheels are thrown in and out. Electric light and power people will look with interest at the final results which will be shown in this remarkable instance of the effective utilization of water power in connection with central station work.

NEW WESTINGHOUSE WORK.

The Newark, N. J., Electric Light and Power Company has been compelled to make some important improvements and enlargements in its incandescent plant. This was necessitated by the great increase in the demand for the light made upon the company by its many customers. The corporation has been very successful in the establishment of the electric light plant, which has been on a paying basis from the very day it was organized. A good deal of this success is attributed due to the fact that the company adopted the Westinghouse alternating current system of electric lighting. Apparatus of a capacity of 2,250 sixteen candle-power lamps was installed in the plant at first, and the last increase made the total capacity of Westinghouse alternating current machinery 3,750 lights.

Another town in the Lone Star State has pushed down the breast-works of barbarism and joined the procession in the progress of modern improvements by introducing the electric light within its precincts. This time it is Cleburne, Texas, whose enterprising citizens have formed an electric light company and also made a contract with the Westinghouse Electric Company for one of its 500 light alternating current machines.

THE LAW TELEPHONE COMPANY.

Mr. W. A. Childs, of the above company, 85 John street, reports business as active in all the various departments. The new Law board, building for Philadelphia, is to be about 100 feet long; it will actually bring 10,000 connections within the easy reach of each operator, sitting down. It will, Mr. Childs says with pride, be the most striking exemplification to be found in the telephone field of concentrated capacity and ease of manipulation. The Law battery continues in as great demand as ever, and with it go a great many specialties in the supply line. The company has made a great success lately of its special tables and sets for medical use.

WESTINGHOUSE MACHINE WORKS.

Few persons are aware of the magnitude of this concern and the immense number of engines they are constantly turning out. Their works in Pittsburgh cover two whole squares and still they are cramped and pushed for room. Between 180 and 240 separate engines are all the year round in process of construction, not counting the finished ones in the warehouse ready for shipment, which would bring the number up to 400. Every department is systematized and complete in in itself. All their molding is done by themselves in their own foundry. Their bouchings, eccentric brasses, and all their anti-friction metal is made from their own mixtures, differing with the particular use to which it is to be put. They make their own forgings—from the smallest to the largest—under their own hammers, and, finally, after the engine passes to its completion, it is not only tested thoroughly, but all the data of tests are kept and filed, signed and vouched for by the very names of the particular men in the shop by whom the tests are made. If, after the engine has been sold, the purchaser complains that its performance is not satisfactory, that his indicator cards show certain irregularities of valve setting, etc., these faulty cards are sent for and compared with the test ones on file, and experience usually develops the fact that the complainant's engine is less to blame than the manner in which the card is taken or the indicator set.

There now 508 men employed at the Westinghouse machine works, and when their building additions and improvements are effected even this large number will be increased.

One would naturally imagine that the working head of this vast establishment would be a very busy man. He doubtless is, but Manager Bagaley would impress the casual visitor as the most unconcerned and disinterested man at the works. Great is system!

The Westinghouse Machine Company, of Pittsburgh, sold during May 79 compound engines, with an aggregate horse-power of 5,005. A number of these went to France and Germany, and one 75 h. p. Standard went to Brazil. Two 250 h. p. engines were sold to the Detroit Electric Light and Power Company, and a similar one to the Excelsior Electric Company, of Port Huron, Mich.

THE ELECTRIC MERCHANDISE CO.

Mr. W. R. Mason, the general manager of the Electric Merchandise Co., 11 Adams street, Chicago, has issued the following notice to their friends and patrons: "We have purchased the merchandise business of the Sprague Electric Equipment Co., and shall carry on the same at the above address. We shall continue to manufacture appliances of all kinds for use by electric railways, irrespective of system used, and shall carry a large assortment and complete stock of all devices used by the respective systems, in station, car or line work. We have in process of manufacture many improvements in car fittings, line material, etc. It will be our earnest endeavor to have the very best material in the market at the lowest price and guarantee promptness in delivery. Our catalogue and discount sheet will be mailed on application. Hoping to merit your patronage and soliciting correspondence in relation to electric railroad building, extensions, supplies, etc., we are," &c.

EUREKA TEMPERED COPPER.

The Electro-Dynamic Co. of Philadelphia, in a recent letter to the Eureka Tempered Copper Co., of North East, Pa., say: "It is with much pleasure that we are able to state that we have used about one thousand pieces of your tempered copper with entire satisfaction. We have found the metal to be of uniform hardness and entirely free from flaws or blow-holes. As cast copper we regard it as a superior article."

THE McINTIRE SPECIALTIES.

C. McIntire & Co., 13 and 15 Franklin street, Newark, N. J., are pushing their well-known electric wire connectors and terminals in the electric light and power field as well as among the telegraph and telephone people. Their more recent productions include lamp and cut-out terminals, which are turned out for all makes and sizes of lamps. They also make patent lightning arresters, in use by the Metropolitan Telephone Company, of this city.

STANDARD UNDERGROUND CABLE COMPANY.

The new factories now being built by the Standard Underground Cable Company at Brinton, Pa., are to be completed and in operation early next November. The enormous increase in the business of this company has made necessary a corresponding increase in the manufacturing facilities. Mr. J. W. Marsh, the secretary, has just been formally elected assistant general manager, retaining also the title and duties of secretary. All who know Mr. Marsh will admit that this recognition of his services and ability is well deserved, and will hasten to congratulate him.

THE SCHISEOPHONE.

This instrument, which is due to Captain du Place, is, like the "electric acoumeter" described in THE ELECTRICAL ENGINEER recently, merely a modification of Prof. Hughes' sonometer. The object of the schiseophone is to facilitate the detection of flaws in metal bars, etc.; and according to our French contemporaries, some recent trials of this apparatus at the Ermont workshops of the Northern Railway of France have proved it to be practically useful. The instrument comprises a striker and an audiometer. A steel rod is moved to and fro in front of a microphone, periodically striking the metal bar under examination. Two coils, one movable and connected to the microphone, the other fixed and connected to two telephones, are arranged on a graduated rod. Having placed the movable coil so that the telephones are silent so long as the hammer is striking a solid portion of the metal, the hammer is moved along the bar, and should there exist a flaw in it, the increased noise given out causes more powerful currents to flow in the microphone circuit, with the result that the telephones are no longer silent.

C. J. KINTNER.

Mr. C. J. Kintner, the well known expert and patent solicitor, has been made the expert of the Aldrich Court plant, this city. Mr. Aldrich has set apart a room for him for laboratory purposes. He will be supplied there with direct and alternating current for expert purposes, and will shortly be ready to make all classes of tests.

NEW YORK ELECTRICAL MANUFACTURING COMPANY.

A few months ago Mr. Augustus Noll, one of the pioneers in the electric wiring and installation business, organized the above company, and believing in the future of the motor industry secured control of the Barriett motor. He opened offices in the Western Union building, corner of Fifth avenue and West Twenty-third street, and also started a factory in this city. Since that time, he has devoted his energies and a considerable sum of money, to the improvement of the Barriett motor and the construction of new sizes, the factory being under the personal direction of Mr. Barriett who, it may be said, is an electrical engineer without a superior in the details of mechanical work. The new Barriett motors embody a number of new features of merit, and Mr. Noll deserves the highest praise for his insistence on thoroughness and excellence of workmanship in every motor that leaves his shops, which by the way, are fitted up with all the latest and best machinery as well as a large number of special tools invented by Mr. Barriett himself.

It should be mentioned also that Mr. Noll's long experience as a construction engineer causes his services and opinion to be in constant demand for various classes of work, and hence the factory of the company is not less busy on special orders entrusted to him for execution. Altogether the New York Electrical Manufacturing Company will have a summer full of occupation and yielding its fair proportion of profit.

THE BAXTER ELECTRIC MOTOR COMPANY.

The New York *World* of June 15 contains an illustrated article on the Baxter motor and works. It is stated that there are now over 4,000 Baxter motors in use, and the company are preparing to make larger sizes as well as to undertake work in several new departments. Special attention is called to the arc motors, the success of the company having largely been achieved in this special field, in which it was a pioneer. Since its re-organization the company has met with a most encouraging reception for its product.

The article referred to says: "The Baxter Company have plans worked out for electric generators of large sizes up to 500 and 1,000 horse-power, and will soon have such machines on the market.

"They are also getting ready to place upon the market electric pumps, which will be a combination of an electric motor and a pump; just so much so as a steam-pump is a combination of a steam-engine and a pump. This will be a great improvement in this line. At present a large number of motors are used to run pumps for elevator purposes, but as there are no electric pumps the arrangement now employed is to use an ordinary power pump, which is run by a belt from a counter-shaft, this counter-shaft being driven by an electric motor. This is a clumsy arrangement and takes up a good deal of unnecessary room.

"They are engaged likewise in making experiments on a new electric railway system which they believe will be a complete solution of rapid transit in cities. The system they are working on is one in which the power to run the cars will be applied directly to the car-axle, thus dispensing with all the complicated gearing and mechanism now used to connect the motors with the car-wheels."

WESTERN TRADE NOTES.

Mr. John H. Finney, of the Cincinnati office of the Westinghouse Electric Co., was in town this week on important business for the company.

Mr. J. C. Liggett, who had charge of all the wiring and construction work of the Westinghouse station in Evanston, Ill., has been appointed superintendent of construction of the new Edison 20,000 incandescent light station which is being put in at Milwaukee.

Mr. Frank Henderson, Gen. Supt. of the Eureka Cement Co., of Owosso, Mich., is in town installing and introducing their new system of covering pulleys, which has numerous important advantages over the ordinary methods, and by means of which all belt-slipping is entirely eliminated.

The Central Electric Co., 116–118 Franklin street, Chicago, report the demand for their famous okonite wire as being very great and extending all the time. They are doing a big business in electric light and railway supplies, particularly among their specialties. They have recently been appointed Western agents for the Globe Fan Company, of New York, and are rapidly introducing these very desirable fans, which can be operated either by an electric motor and primary battery or any other suitable power.

Mr. Morris, of the Novelty Electric Supply Company of Cincinnati, is in town, where he will remain for about a week. He is spending his time calling on his various customers and friends, showing them his most recent specialties in line, electric light and power and electric railway supplies. He has some remarkably good things in this line ready for the market, and numerous others which will be introduced in the very near future. The company are doing a large business and enjoy an enviable reputation for the excellence and durability of their goods, which are in large demand everywhere.

Mr. Myron A. Knapp, of the Knapp Electrical Works, has been very actively engaged for the last few days in fixing up his building—kalsomining, papering, painting, etc., those portions which were injured by the recent fire on his premises. Notwithstanding this occurrence, with its many drawbacks, his large orders were all promptly shipped, and the business conducted as expeditiously as if nothing of the kind had happened. Grimshaw White Core wire, Perkins lamps and Mayo motors are selling all the time, and the prospects of the company for the future are exceeding bright and hopeful.

Mr. M. E. Baird, of the Eddy Electric Motor Company, of Windsor, Conn., is in town for a few days looking after some of the Eddy interests in this section of the country. He reports the business of the company as in splendid shape and continually increasing. The general merits and fine mechanical and electrical workmanship of these machines is finding for them a ready sale, and purchasers are unanimous in their expressions of the thoroughly successful way in which they do their work. The company is ably represented in the West by Mr. G. A. Edward Kohler, who has fine offices at room 329 The Rookery, where he is at all times glad to explain the operation and mysteries of his motor to the uninitiated.

Mr. Forée Bain has just returned from a trip to the coal mining regions of Iowa, where he has been carefully looking over some of the mines located there, with the view of fitting out two of the largest with a complete equipment of electric machinery, comprising motors for transmission of power, dynamos and electric lighting apparatus. Mr. Bain is remarkably busy building his new motor-dynamos, which were illustrated and described very fully in a recent issue. These machines are giving very excellent satisfaction among their users. One recent order alone amounted to seven 15 horse power motors. This machine is of very solid mechanical construction, simple and not liable to get out of order, and its electrical conditions have been most thoroughly and carefully worked out, thereby obtaining very high efficiency in operation.

The Munson Belting Company are very busy putting in their new machinery, to accommodate which they have largely increased their floor space. Their business is on the increase all the time and orders come pouring in from all sides. Col. Shay the "electrician" of Munson Belting fame, so well known in central stations all through the country, has just returned from a trip to St. Louis, where he captured a fine order for 266 feet of 54-inch and 300 feet of 16-inch belt. Your representative had the pleasure of being shown over the factory by Mr. Morgan, who took the greatest pains in explaining the ways and methods of manufacturing belting of the finest quality and the modus operandi of the various labor-saving and perfecting machinery. None but the very best quality of leather is used in the manufacture of this belting and infinite trouble is taken in the various processes to produce the finest possible product, in which, if we may judge from their large business and the high esteem in which this belting is held, the Munson Company are eminently successful.

NEW ENGLAND TRADE NOTES.

Messrs. Bird and Sloane, have formed a company for the purpose of doing all kinds of wiring for various electric purposes. Mr. Bird was formerly with the Edison Electric Company, and Mr. George H. Sloane is the well known inventor of the "Advance" primary battery. Their headquarters are at 44 Sudbury street, Boston.

The Thomson Electric Welding Company has just made a contract with the Roebling Manufacturing Company of Trenton, N. J., to supply seven additional welding machines. They have also made contracts with the U. S. Government to install the welding plants at the New York and Norkfolk Navy Yards, and with the Pennsylvania Railroad for a large plant at the Company's works in West Philadelphia.

The Providence Construction Company, of Providence, R. I., of which Mr. E. W. Fyler is manager, are making a specialty of enameled wood electric light specialties, which are in great demand. They make adjusting balls, rosettes, lamp socket bushings, adjusting "peanuts," etc., in various colors, which are cheaper than rubber or other material, and yet present a highly finished and artistic appearance for a very moderate price.

The Smith Electric Company, of Attleboro, Mass., are now doing a large manufacturing business of electric bells, gas lighting keys, nickel press buttons, switches, door pushes, spark coils, incandescent rosettes and batteries of all kinds. Mr. Smith manages the business personally, and has by continued and persevering application built it up in the past year to quite a successful issue. The goods are all first-class, and he has special facilities for the economical and correct production for all kinds of electric work.

The Municipal Signal Company, 79 Franklin street, Boston, has lately been awarded the contract for the equipment of three police precincts in San Francisco with their well-known "Police Alarm and Inter-Communication System." Capt. Rosell, of the U. S. A. Engineers, who lately visited Boston and other cities under orders to investigate the merits of existing systems of police alarm in order to determine what system should be used in Washington, D. C., has made a report in favor of the Municipal System, and the District Commissioners have unanimously awarded the contract for the equipment of the Georgetown police precinct to the Municipal Signal Company.

The Standard Electric Time Company, of New Haven, Conn., have begun to extend their business into Canada, and are busy working up this new field. They have recently placed a plant consisting of one regulator and eight clocks in the mills of The Rosamond Woolen Company, at Almonte, Ont., which is giving entire satisfaction. Probably the finest plant which they have ever installed, is the one which they recently sold to the new Bank of Commerce building in Toronto, which is one of the finest buildings in Canada, the inside being extremely handsomely decorated. The plant consists of one regulator and seven clocks, and the whole of the fittings had to conform to the interior decoration of the building, the dials being specially highly finished. The dial in the main banking hall is three feet in diameter, black with gilt hands and figures, and is contained in a handsome hand carved cherry wood case six feet high.

Mr. Philip Bell Downing, of Boston, has recently invented and patented a mechanical device for operating street railway switches, which are peculiarly adaptable for electric railways. The parts are all strong and direct-acting, and the switch is not at all liable to get out of order. This mechanism is operated in two ways—one by the wheels of the car and the other by an independent wheel or axled sphere in control of and operated by the driver, by means of a brake handle. When a car has switched off, and the one following it is to continue on the main track, the switch is thrown back automatically by the wheels of the car; but when it is desired to go off from the line and follow the car switching off, then the driver turns the brake handle and the sphere-wheel is brought down to the surface, strikes the projecting stud of the switch mechanism, the switch is turned, and the car goes on to the branch line without interruption or failure of any kind—the wheel of the car following striking another stud as it comes along and setting back the switch so that the line is continuous. The switch is well adapted for horse, electric and elevated roads. Its strength, simplicity, quick and positive action all render it a most complete device for the purpose for which it is intended, and all the leading street railway and electric railway men who have seen it pronounce it to be entirely satisfactory.

NEW YORK TRADE NOTES.

Mr. Y. J. Symmes, president of the well-known gasfixture house of Thomas Day & Co., limited, of San Francisco, was in New York last week on electrical business.

ST. LOUIS TRADE NOTES.

Mr. B. J. Arnold, engineer and agent for the Thomson-Houston Electric Co., has removed his office to room No. 115 Chamber of Commerce building.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. IX. NEW YORK, JUNE 25, 1890. No. 112

> ***The general public have but a limited understanding of the great growth already attained by the industries devoted to the practical application of electricity and the enormous development of which they are capable.—Henry Villard.***

UTILISING WATER POWER ELECTRICALLY.

THE extent to which water power is utilized in the manufactures of the country has not arrested attention as it deserves. The returns of the Tenth Census, that of 1880, showed that there were in use in the United States no fewer than 55,404 water wheels developing a total of 1,225,379 horse-power, or 35.93 per cent. of the total power employed for industrial purposes. In view of the extension of water power plants since 1880, there can be no doubt that the increase in this field will again be considerable even if it has not kept pace with the growth of steam power. Such places as Minneapolis and Appleton are largely the product of the last decade, and there has, moreover, been a very considerable development due to the introduction of the electric light. The last census took no account—for there was none to take—of the use of water power in generating current for light and power; but the special electrical census this year will include hundreds of wheels throughout the country of a total capacity of many thousand horse-power, operated solely in connection with dynamos.

It is, in fact, in the electrical field that the turbine builder must look for much of his new business, and it is certainly a department worth cultivating. Instances like Rochester, or Kearney, or Spokane Falls at once come to mind; and they are destined to be more plentiful as the idea is realized that the energy of our water powers can thus be distributed economically over a very large area by means of wires and motors. The plans for Niagara are now well matured, but there are other propositions even further advanced to the stage of execution. Thus, Col Whittemore, of the Government Arsenal at Rock Island, Ill., in his report to the Chief of Ordnance has submitted plans for the electrical transmission of power from 41 wheels, the dam for which is now being built. His intention is to connect these wheels directly with dynamos, and to carry the current to motors scattered all over the rapidly growing shops. The estimate is made of an expenditure of about $50,000, to start with, for the transmission of current both for light and for power. Some fifteen years ago a Board of Ordnance officers recommended transmission from the wheels by means of rigid shafting continued with wire rope. To-day, however, electricity is seen to be by far the most flexible and economical method, and the carrying out of such a plan will be another exemplification of the great advantages that electricity offers.

We trust that this subject of the electrical utilization of water powers will hereafter command more attention. We know of more than one place where a sure return awaits the enterprising capitalist, and some of them are not far from New York. There are water powers that even electricity cannot reclaim, but leaving such aside, the residue presents a field of magnificent opportunities. An official calculation upon the best data obtainable brings out the extraordinary fact that the rivers and streams of this country, averaged throughout the year, show over 200,000,000 horse-power. At the present time, allowing the total of 1880 to have been doubled, we are using just 1 per cent. With the help of electricity it ought to be at least 5 per cent.

MAGNETIC TELEPHONE CONDUCTORS.

IN another column we have described a novel method by which an inventor hopes to maintain telephonic conversation without the employment of the carbon transmitter, depending solely upon the variation in the magnetic state of the core by the vibration of the diaphragm before it. In order to accomplish this, the inventor converts his entire conductor into a kind of solenoidal magnet by passing the transmitting current around it and back through it. In the lack of definite information as to the length of line thus far operated upon, it would be impossible to predicate possible results; but certain considerations seem to point to difficulties which would be encountered in such an arrangement. While it is well known that a long magnet such as that of the nature described, will give a strong magnetic pole, it is also one which is endowed with great coercive force, in virtue of which it acts very slowly in giving up, or receiving, its magnetism. Thus experiments have shown that a long soft iron wire acting as the core of the magnetizing coil was able to sustain a weight long after the current had ceased. This magnetic retentiveness of long magnets, and vice versa the greater sensitiveness to change of magnetizing current in short magnets, is the principal reason of the general adoption of short magnets in the construction of dynamo electric machinery. We hope the inventor of the telephone system described will soon be able to furnish particulars of its practical operation.

CURRENT AND COEFFICIENT OF FRICTION.

THE important part which the phenomenon of increase in friction between metallic surfaces traversed by a current may play in the future in its application to various purposes makes any contribution on the subject of value at this time. Our columns have quite recently been devoted to the recording of the results obtained by Messrs. Daft, Crosby, Blake and Ries, the last of whom has perhaps carried his experiments farthest in a practical direction. While all of these agree that an effect such as originally pointed out by Mr. Daft takes place, and ascribe it to the production of heat, there is a difference of opinion as to the relative increase of traction obtained with a given current. The latest experiments which we note in another column, and are due to Mr. Levy, go to confirm the results obtained by Mr. Ries, especially on the paradoxical increase of friction due to oiling the rails in circuit. While up to the present time both forms of current, continuous and alternating, have been employed in these experiments, no comparative data has been published, and it would be interesting to see determined the relative efficiency of the two forms of current in that respect. We hope the subject will soon be taken up.

ELECTRIC POWER RATES.

IN our last issue we gave a few illustrations of the manner in which the electric power business had now come prominently to the front as a means of providing daytime work for central stations. It is to be borne in mind that the motor business depends largely for its success upon the rates at which the consumer can secure his current. We have received within the last few days the new schedule of power rates recently adopted by the Brush Company of Baltimore "after a very careful consideration." It is as follows :—

1-10 h. p.	$ 2.50
¼ h. p.	3.00
½ h. p.	5.00
1 h. p.	10.00
2 h. p.	16.00
3 h. p.	21.00
4 h. p.	26.00
5 h. p.	30.00
6 h. p.	33.00
8 h. p	42.00
10 h. p.	50.00

This scale, which goes into effect on July 1, seems reasonable for a city presenting such conditions as Baltimore does, with a large population engaged in a variety of pursuits but not distinctively of the industrial type and not presenting so great a diversification of small industries as one finds, for example, in Boston or Newark. Still the motor business has been fairly well worked up in Baltimore, and there are now 375 motors representing about 200 h. p. of daily consumption of current. With the revised schedule this number and quantity should increase quickly.

Primary Batteries at the Paris Exposition.

WITH this number we bring to a close the official report on primary batteries at the Paris Exposition, by Mr. Carl Hering, which stands as an excellent review of the state of the art at the present time. It is interesting to note the modifications which the Leclanché cell is undergoing. They bid fair to reach in number those which the Bunsen cell has given rise to. The recent introduction here of the Edison-Lalande battery makes the detailed information as to similar cells exhibited at Paris timely. One of the most striking points brought out is the great increase in output of the cell on the increase of its temperature due to the fall in internal resistance. This marked action is suggestive of methods which might be turned to useful account.

Mr. Villard's Electrical Projects.

THERE can be no doubt of the fact that the magnificent field for development by capital that is now presented in the various branches of electric light and power has appealed very effectually to the imagination of Mr. Villard. He is one of those brilliant men of affairs whose insight and foresight, as well as influence with capital, are so necessary to the building up of new enterprises on the large scale ; and now that he has found out by his association with the Edison Company what the opportunities are, he cannot but go forward. His ideas on the subject may be seen in the circular signed by him which we print in this issue. Aside from the general aspects of the situation there touched upon, there is special interest in his utterances regarding the Edison and Thomson-Houston Companies. He thus confirms officially what we have already hinted at more than once as to their friendly relations ; but it by no means follows even now that there is to be, or will be for a long time yet, any actual consolidation and amalgamation. In Boston, some of the papers have gone so far as to effect a wholesale combination, in which such names as Villard, Coffin, Westinghouse and Edison are assembled in a most striking manner. Such an array of genius and talent might well direct such united forces as are thus implied—but the truth is the conditions are not quite all that is stated by the financial writers in question.

Trusts and the Law.

WE print in this issue an article from Mr. C. A. Brown, whose business responsibilities have not prevented him from excelling in the law. He has lately made a special study of the many vital questions involved in trusts, and as the subject is one not less interesting to those engaged in electrical industries than to others with capital and experience invested in plants and factories, we have gladly given space in our columns to his clear, crisp and dispassionate presentation of the case and all that it involves.

The Copper Market.

ELECTRICAL engineers are beginning to look a little askance at the later quotations of the copper market, and do not altogether like the rising tendency that has been manifested. Still, as has been said recently, "a 16 cent market for the product is a tremendous incentive to increase in production," and possibly some relief lies that way by and by. It is interesting to note, in this connection, that the supply of electrolytic copper is steadily increasing. The quantity made in this country last year is said to have been not less than 20,000,000 pounds. New copper producers will greatly increase the supply this year. The notion that the demand from electrical companies for copper is not of a permanent nature has now been very thoroughly dispelled, and the electrical consumption to-day is not among the least important factors in calculations as to prices and supplies.

ELECTRICAL ENGINEERS.

CHARLES J. VAN DEPOELE.

It is but natural that one who has done so much for electric railroads should have been brought up among railway men and railway shops. Charles J. Van Depoele was born at Lichtervelde, Belgium, in 1846, and from an early age displayed an interest in machinery, the taste being inherited from his father, who was for several years master mechanic of the East Flanders Railway shops at Poperinghe. In 1856 young Van Depoele saw the telegraph system of the road put up, and by the time it was completed was perfectly familiar with the apparatus and its modus operandi. He built apparatus of his own of the same nature, and read through every book the college offered on natural philosophy and electricity. When he had reached the age of thirteen his father was so well satisfied that he brought his education to a summary end in spite of the appeals of his professor and the principal of the college. Nothing else would do but an apprenticeship in cabinet making; and the boy was set to work planing rough boards, on the magnificent allowance of five cents per week.

Charles J. Van Depoele.

In the odd hours of his scanty leisure he still built and experimented with electrical apparatus. He made a Ruhmkorff coil with No. 34 wire, using an automatic winder of his own design; but his father found it out, and, believing his prospects to be imperiled, confiscated his books and destroyed the coil. He was then put in charge of an uncle and aunt, who were strictly enjoined to "keep him out of mischief;" and as his working hours often ran from 3:30 a. m. until 9 p. m., it may be surmised that he had little chance to indulge in his favorite pursuit. Still he did contrive to make sulphurous acid before daybreak, and, of course, was found out, the process not being one that lends itself to easy concealment.

At the age of sixteen he had mastered his trade. He was set up in a shop of his own, and soon employed half a dozen men, making all kinds of furniture. He seized every opportunity for study, and went so far as to construct a Bunsen battery of 40 cells. This, however, was carefully hidden from his father, between the joists of the top floor of the house, and there was left when the family removed to Lille, France, in 1864. Young Van Depoele did not take kindly to the furniture industry which his father established there successfully, and therefore was allowed to secure a position in the sculpturing ateliers of Buisine-Rigot, where some 250 artists and artisans were employed. He soon rose to the position of foreman, and also distinguished himself by making an altar for a church at Shanghai, China, an immense piece of carved work sixty feet high by forty feet wide. He now made plenty of money, part of which went to his mother, but no small portion was spent on electrical books and apparatus. The paternal restraint and disapproval were, however, very irksome, and at last he resolved to come to America, where he would be free to gratify his tastes to the full.

He arrived in Detroit in the summer of 1869, and there, with a Belgian friend, started the manufacture of art furniture, thus being a pioneer in that now great and prosperous industry of the West. As the business grew, its income grew, and Van Depoele built himself a battery of 100 Bunsen cells, with which he produced the electric light. From that time on, for several years, despite the wishes and protests of his friends, he spent all of his leisure and much of his ample revenues from the furniture business in electrical experiments. When the Gramme machine was brought out he at once made a dynamo after the description given, and was so much gratified with the results that he constructed several other machines of the same type. So interested was he that, though the day was devoted religiously to his business, he was delighted when the hour came for the men to quit work, and he was at liberty again to try some new experiment.

This state of affairs lasted until 1877, when he built an electrical laboratory and there constructed several large dynamos, with which exhibitions were given. His large shop was brilliantly illuminated by from four to eight arc lights. On one occasion, during a fog, he placed a large arc lamp on top of his shop, and the extraordinary glare brought out the city fire department. In 1878 he lit up Forepaugh's circus, and after that Recreation Park was illuminated nightly for the benefit of baseball enthusiasts. The same year he made a contract to light the front of the Detroit Opera House. One or two propositions were now made to him looking to the formation of a company, but nothing was seriously done until 1881, when, having established himself in Chicago, a strong company was formed, in which Gen. A. K. Stiles was the chief stockholder. Within a year from the start over 100 men were employed in their shops, and a successful business was done, in spite of the competition that now began to make itself felt in this field.

Mr. Van Depoele not only gave attention to the development of his arc lighting system, but investigated the question of electric power, and worked out various devices for "telpherage" and the running of tools by electric motor. A great hobby of his was the propulsion of street cars by electricity, in which his first experiments were made in 1882. His first commercial road was equipped in 1885 at South Bend, Ind., where five cars were run at one time—something never done before, and even then regarded very sceptically. The work thus begun went on apace, and by 1888 the Van Depoele Company had no fewer than thirteen roads in operation on the overhead wire system, the plans and designs for all the apparatus throughout being worked out by himself, and many of the roads remaining in successful operation to this day on the original methods.

In the spring of 1888 the Van Depoele Company sold out their electric railway system, patents and business to the Thomson-Houston Electric Company, of Boston, whose service Mr. Van Depoele thereupon entered as electrician of the railway department. Everyone is familiar with the enormous strides made by that company in electric railway work since that time.

It is worthy of mention that Mr. Van Depoele claims to have been the first to run a number of cars from a single source of constant potential, using separately excited generators. In the fall of 1885, when the South Bend road was constructed, he had five cars in operation, four of 7 h. p. and one of 10 h. p., the motors being under the car floor. At the time he did this, no road, it is said, had more than two cars at most in operation at the same time.

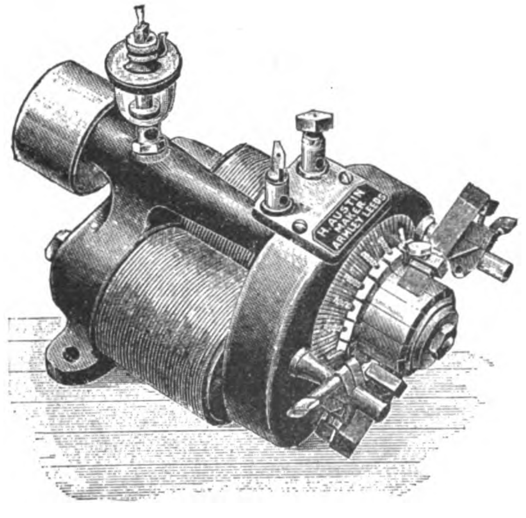
Not only has Mr. Van Depoele developed the lighting and traction systems bearing his name, but he has produced a great number of commutatorless motors, both rotary and reciprocating, the latter being specially adapted for rock drilling. In fact, some of his drills were tested for coal mining as far back as 1885. He has lately devoted considerable attention to the subject, and promises to bring out soon some perfected apparatus. These drills are operated by direct pulsating currents, require no commutation, and owing to their extreme simplicity are not liable to get out of order. Mr. Van Depoele is applying the same principle to forge hammers, riveting, etc.

This brief record does bare justice to the persistency with which Mr. Van Depoele carries out his inventions and ideas. He is indefatigable, and is also able to maintain his good nature and courage amid disheartening difficulties and setbacks. In capacity for hard work he is not excelled.

The portrait of Mr. Van Depoele on the preceding page is from a recent and faithful photograph.

AUSTIN'S INFANT DYNAMO.[1]

Under the name of the Infant dynamo, Mr. H. Austin, of Armley, Leeds, is introducing a machine which he hopes may meet the demand for small dynamos, having equal merits with the larger ones as far as regards good output for power absorbed. He commences where other makers leave off, namely, at one unit, the range of sizes being 1,000, 700, 400, 200, 100, and 50 watts. These are all made alike in every detail, differing only in size.



Austin's "Infant" Dynamo.

The armature core is made up of thin best Swedish charcoal iron rings (No. 18 B.W.G.), accurately turned both inside and outside by special machinery. The sharp corners left on in turning are all carefully ground off each separate ring, which is then coated on both sides by a varnish made up of very thin shellac varnish, in which is mixed some fine plaster of Paris. The core is then built up to the required depth, the separate pairs of rings, while under pressure, being carefully tested for insulation, and mounted on a strong spider of hard brass. The core is then well insulated, and wound in the Gramme fashion. The commutator is made up of segments of brass of a special quality (carefully insulated with asbestos or mica), and has a good wearing depth. The field magnet cores are made of best Swedish iron, carefully annealed, and are screwed into the pole-pieces—the pitch of thread being very small—a method which gives a very good contact between the two surfaces. The yokes are very massive, having a sectional area three times that of the cores. The bearings are of very hard phosphor bronze, and are of good length. Each dynamo is fitted with a sight-feed lubricator. The used oil finds its way by suitable passages into the oil dish under the yoke of the magnets. There is only one lubricator to each dynamo, the oil entering between the two brushes and working outwards, thus keeping the bearings perfectly clean.

ELECTRIC MOTORS AND CHURCH ORGANS.

It is now some time since that the great organ of St. Paul's Church, in this city, was equipped with an electric motor for blowing the bellows, and the success which was there attained in evenness of pressure and volume has called forth the approbation of all who have had occasion to witness the operation of the simple but effective installation.

Indeed so successfully has the work been accomplished that the C. & C. Electric Motor Co., the designers of this plant, have been called upon to make similar changes in nearly a dozen of the largest churches in this city, including St. Patrick's Cathedral, St. Thomas's, Calvary, Trinity and others.

In a handsomely illustrated catalogue just issued by the company there are described the most prominent of these installations, each one of which has demanded the fulfilment of some particular conditions, and the successful accomplishment of which attests again the adaptability as well as flexibility of the electric motor in all situations.

As an example of this we may cite the case of the large organ in old Trinity, on Broadway, facing Wall street, in this city. The scale of the pipes in this organ is larger than that of any other in this country, and many stops have from time to time been added to it without at the same time enlarging the bellows. The latter, as originally designed, were too small for the work which they had to do, and the needed addition to them was never made. To answer satisfactorily, therefore, this great demand was indeed a problem, but the electric motor as installed satisfies all the requirements put upon it.

The organ is located virtually in the main body of the church, the large ornamented pipes that form its front merely shutting out the view of the more unsightly portion behind, and any noise made there is instantly caught by the arch over head and made to reverberate through the building. Even here, however, the electric motor performs its work so noiselessly that nowhere in the church is the slightest sound from it perceptible, a result which it is safe to assume that electricity alone could attain.

The accompanying engraving shows clearly how the motor is attached to the organ. The belt from the motor runs to a large pulley on the counter shaft on which are two driving pulleys leading to pulleys on the driving shaft. Each bellows controls a part of the organ, and they are both automatic in their working and when full are made to cut off. When, however, one part is used beyond its capacity, an automatic arrangement opens a connection between both bellows, causing the secondary bellows to aid the primary, thus insuring an abundance of wind without straining either bellows. The motor is started from the key-board, and since full power can be obtained at any instant, a power of tone never before heard surprises even those who are most familiar with this grand old organ.

In the installation at St. Patrick's Cathedral the small organ is so placed that the motor has to stand in the very chancel, but it is impossible to perceive the slightest sound from it. The speed of the motor in this case is regulated by a resistance box. The lever on the box is connected to the bellows, and their movement causes more or less resistance to be thrown into the motor, thus automatically regulating its speed to conform with the needs of the organ.

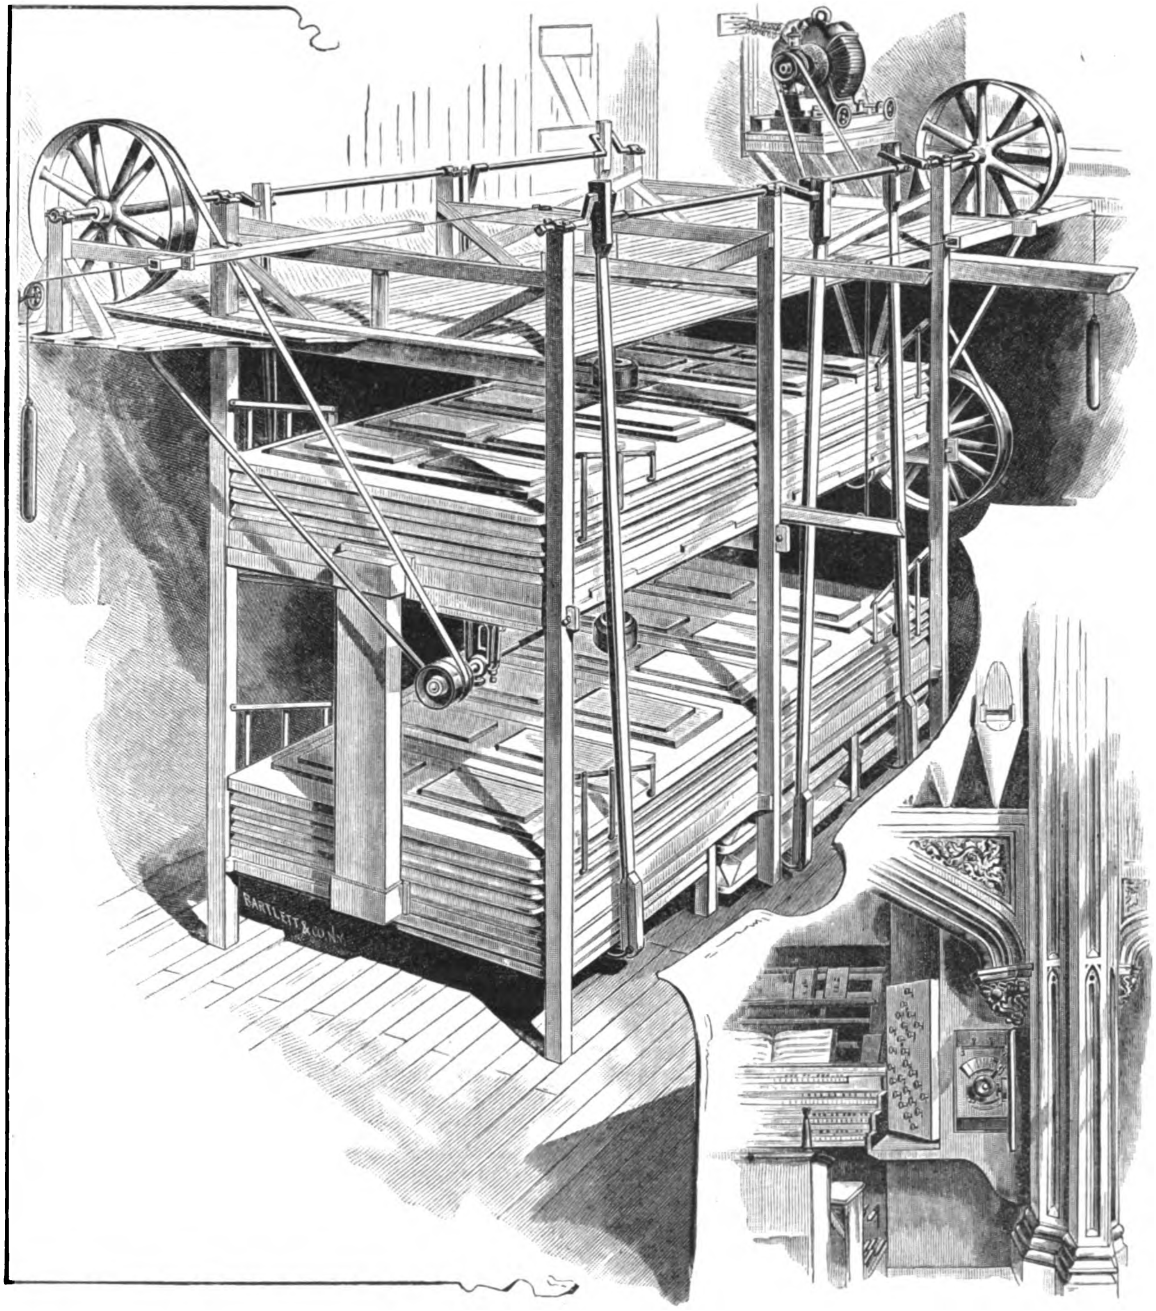
---

[1] London Electrical Review.

Perhaps the most compact plant yet installed is that in the Church of the Holy Communion. The pulleys, counter shaft, driving shaft and motor are all placed under the bellows, and the whole arrangement occupies a space about five feet by two.

The installation at the Collegiate Church at Twenty-ninth street and Fifth avenue very neatly solves the problem of a compound organ. This organ has two bellows; one supplies the entire organ with the exception of one register, which is supplied by a high pressure bellows. The arrangement is such as to throw this bellows into automatic action when the stop is drawn, thus making the supply of wind available. When the stop is put in, the automatic arrangement is checked and the supply is cut off.

It is needless to say that the C. & C. Company, who have made a specialty of this class of work, have relieved the organists of the churches they have equipped of a constant source of annoyance, and the latter have been most unanimous in testifying to the superior qualities of the electric motor as a source of power for their particular needs.



BARTLETT & CO. N.Y.

Church Organs Blown by Electric Motor.

THE GOVERNMENT AND TELEGRAPHY.

The Postmaster-General has issued an order fixing the rates on Government telegrams for the fiscal year, beginning July 1, 1890. The rates are exactly the same as those of the present fiscal year. That is, on day messages, ten cents for ten body words, for not over 400 miles, and half a cent for each additional word. Fifteen cents for ten words between 400 and 1,000 miles, and three-quarters of a cent for each additional word. For a greater distance than 1,000 miles half a cent extra for each word added to the price of the message for between 400 and 1,000 miles. For night messages fifteen cents for twenty body words for all distances, and half a cent for each additional word. For signal service weather reports two and a half cents for each word sent over each circuit established by the Chief Signal Officer.

THE FALLACY OF MUNICIPAL CONTROL OF ELECTRIC LIGHTING.

BY M. J. FRANCISCO, PRESIDENT, RUTLAND, VT., ELECTRIC LIGHT COMPANY.

I FIND in THE ELECTRICAL ENGINEER of June 4th an article by Victor Rosewater, of John Hopkins University, in which an effort is made to show the benefits to be derived by a city owning an electric light plant. I understand that this gentleman is one of Prof. Ely's pupils, and of course he is giving the public the professor's views and teaching. The author takes the position that the interest of the stockholder and the citizen are directly antagonistic. If this is the case, is not every corporation in this country in the same condition? Is not a stockholder in an electric light company governed by the same conditions that control other enterprises? Mr. Rosewater claims that hired politicians, whose tenure of office is but for one year, without experience or knowledge of the business and with no financial interest in it, with the exception of their salaries, will give the tax-payer better service than the private corporation! The manager of an electric light company, however, is personally interested and knows that its success depends upon his furnishing the best service at fair rates. Now, in order to accomplish this, it is evident that he will bring to his aid all that years of experience have taught him is best in electrical apparatus, together with the latest inventions and improvements.

If a city can sell electricity why not sell groceries and dry goods? For the merchant makes his profit while the city would sell without a profit. Of course with this plan the business of individuals and of private corporations would be destroyed, and their property, upon which present taxation is based, would be swept away. Under such conditions where would the municipal salaries come from?

There is one point which the author of that article wisely omits to mention. A city invests thousands of dollars in electrical apparatus as at present manufactured. With the rapid strides now being made in inventions, one year hence all machines may be so changed or improved that it would be a direct loss to use the present style. What would the city do? Use the old style, with the cost of producing the lights double what it would be with the improved apparatus? Or throw it out and buy another outfit, and tax the people to pay for that also? If the city own the plant they assume these chances. If a private corporation, it has to provide for just such contingencies, and these conditions have compelled many an electric light company to run years without a dividend or any return upon their investment.

Special stress is laid by Mr. Rosewater upon the statistics collected about a year ago by the Scranton, Pa., Council, and in that list the cost of all night lights in Topeka, Kansas, is quoted at $72 per year. I have a letter signed by the Mayor of Topeka, in which he states that the cost of operating the all night lights has been $11 per month, or $132 per year. Here is an illustration of the value of the Scranton Council's statistics, and also a sample of many garbled statements pretending to show the cost of municipal lighting. Why try to conceal the facts by furnishing only *part* of the expense of the city's plant? Every one knows that if forty or fifty thousand dollars of the taxpayers' money is invested in an electric plant, interest on that investment must be charged as part of the expense. If that money had been loaned to an electric light company, would it not have produced an income to the city? Everyone familiar with the electric light business understands, full well, that the depreciation by use is not less than 10 per cent. per year, and that this is part of the yearly expense. The tax-payers, if the city own the plant, must meet these expenditures the same as an electric light company. Trying to ignore or conceal the truth does not aid their cause in the end. Yet, in all the comparisons made in the article referred to, the prices quoted as charged by the electric light company include these items, while they are all omitted in the cost of lights furnished by the city.

Bay City, Mich., is cited as an example of the success of municipal lighting. The Council of Bay City appointed a special committee to investigate the expense of city lights, and they submitted a report showing that the city was running 137 lights at a cost of $59.42 each per year. This did not include taxes, water rates, interest or depreciation. Including interest, 5 per cent. on $35,000, cost of plant, taxes and water rates, 2½ per cent., 10 per cent. depreciation, the cost was $104 per year each lamp, running only dark nights. A short time since, during a thunder shower, the city was left in darkness, because the city superintendent was afraid of burning out an armature if he ran the lights. What would be the result if an electric light company left the city in darkness every time the superintendent noticed a storm approaching? A gentleman passing an evening in Bay City recently, inquired why they did not have street lights, and the answer was they did have them, and sure enough, at nine o'clock, they started the lights!

Still the price charged by electric light companies for first-class service is compared with such service as this, and if the private company's lights are out for an hour, or not up to full candle power, a rebate is demanded. Before Mr. Rosewater quotes the cost of lights for any other cities he had better obtain the facts, and not lead the public to think that there is a reason why the true data does not appear.

"It may easily be seen that prices in this industry are not governed by the cost of production. The great difference between the average cost to cities illuminated by contract and to those furnishing their own light gives good ground for this inference." Thus, Mr. Rosewater. But is it singular that prices in various cities should differ? In one city the lights are burned until midnight, in another all night; while one uses steam power, the other water; one uses 1200 candle-power lamps, the other 2,000. In one place fuel costs $1 per ton, while in the other it costs $6 per ton. Of course under these varying conditions prices cannot be the same. The very fact that the article referred to gives the cost of lights in cities owning the plant, in comparison with cost of lights furnished by private companies, and does not give the information embodied in the above queries, shows the unfairness of the comparison and the attempt to misconstrue the real facts, leading the public to think the conditions in each place quoted were the same. How is it that in the list furnished of cities owning their own plants, in one it is $23.61 per year, while in others it is $60, $72 and $100 per year? Why this difference in various cities? Why not apply the author's own argument to municipalities as well as electric light companies and claim that city "authorities are swindling the taxpayers because the cost of producing the light is not the same in every city owning a plant?" The committee on manufactures of the legislature of Massachusetts were sent to Philadelphia, Richmond, and Alexandria to investigate the municipal lighting of those cities. They found that the actual loss to the city of Philadelphia last year was $104,145.26, while the annual loss to the city of Richmond was $42,405.97; and the committee reported against Massachusetts adopting such methods. Yet this university man says: "A committee of the select council of Philadelphia was so highly pleased that the municipal gas works are not only paying expenses under its new management, but actually earning a profit, that it reported an appropriation of $300,000 for the extension of the public lighting system to the field of electricity. It was only owing to the influence of the electric lighting corporation that this item was stricken off the appropriation bill." Politicians are generally pleased if they can convince the public that they are the men to keep in office and handle the taxpayer's money. If the electric light companies, by their influence, prevented the city of Philadelphia from wasting $300,000, as the author of that article says they did, the taxpayers and citizens ought to tender them a vote of thanks.

Danvers, Mass., is quoted as one of the cities owning its own plant, and advocates of municipal ownership claim that the cost there is only $45.37 per year to run a 1,200 candle power lamp. What are the facts? Danvers is burning seventy-three 1,200 candle power lamps. The actual running expenses last year were $3,500. Interest on $15,000, cost of plant, at 6 per cent is $900; depreciation by wear etc., at 5 per cent is $750; taxes which the town would have received from the private company are $100, making the total cost, $5,250, or $71 per lamp per year for 1,200 candle power lamps 300 nights until midnight.

The figures given for Danvers show the cost where the city owns the plant at $71 per year, while, by Mr. Rosewater's own list, he shows that private corporations are furnishing Yonkers, N. Y., all night lights for $60 per year; Racine, Wis., all night for $70; Lafayette, Ind., all night for $50. It costs every one of these cities less for all night lights than it costs the city of Danvers for lights until midnight. The fact that these companies are compelled to furnish their lights at such non-remunerative prices, shows conclusively the inconsistency of Mr. Rosewater's claim that electric light companies are a monopoly.

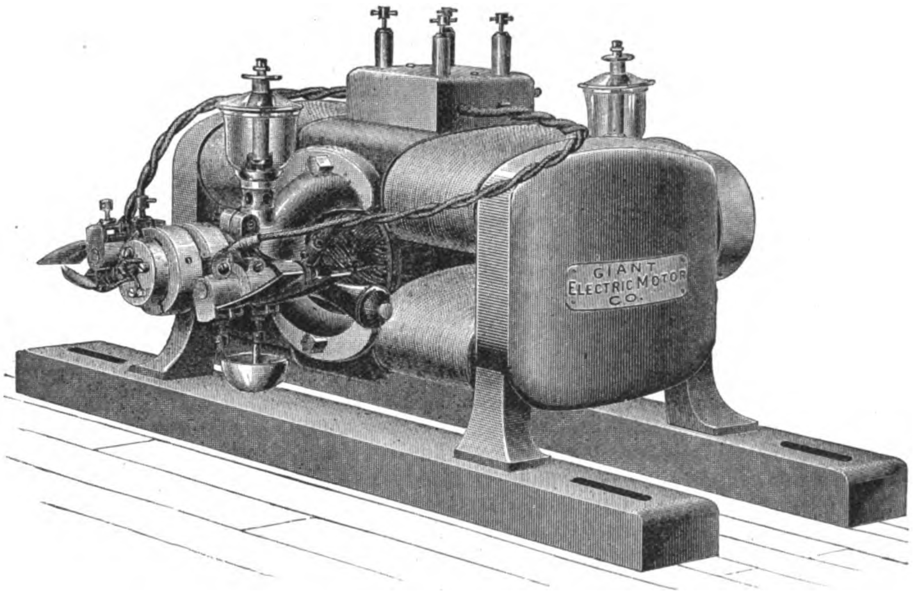
Several cities owning plants, have found by actual experience that the service and expenses relating to the same were unsatisfactory, are now considering the advisability of abandoning the control of the plant, and are negotiating for contracts with electric light companies to light their streets. Philadelphia, owning an immense gas plant which Mr. Rosewater says the "Select Council were wonderfully pleased with, because they were making a profit," has contracted with electric light companies to light the streets for $177 per year each lamp, or more than three times the amount he claims as the average cost for those cities producing their own lights. The taxpayers of Philadelphia have had an experience with both plants, and evidently think any price a private corporation will offer is cheaper and better than municipal control.

No sane or fair minded man will, with the corruption and fraud practiced by politicians at the present day, attempt to prove that it is for the best interest of the taxpayer to place faith in the honest or conservative management of any enterprise which can be manipulated in the political arena for the advancement of the men in power. The histories of New York, Philadelphia, and many other cities are samples of such methods and their purifying effects upon politics. Hypothesis and theory may do on paper, but actual results obtained by practical application and experience are the only reliable data upon which to base any statement relating to the cost of street lighting. In every case these have shown, where all the facts are given, that it has been for the best interest of the citizens and tax payers to contract with an electric light company for lighting the streets of any city.

THE CHAPMAN INCANDESCENT DYNAMO.

We illustrate in the accompanying engraving the Chapman dynamo of the Star Electric Co., of Bridgeport, Conn., in which special attention has been given to the mechanical and electrical design. The armature winding, it will be noted, consists of two coils wound at right angles to each other and connected to a pair of two-part commutators. In order to reduce as much as possible the care required by the commutator, the latter is made of a cylindrical piece of hard insulating material, keyed to the shaft at one end, and two pairs of semi-circular segments of brass secured thereto, and two pairs of semi-circular segments of composition metal secured to the first-named segments by one screw in each segment.

When, in the course of time, the commutator has become worn, it is only necessary to remove the four wearing segments, which can be done in a few minutes with the aid merely of a screw driver, and replace them by a fresh set. This avoids the necessity of removing the armature in order to turn the commutator true.



The Chapman Dynamo.

The two independent coils on the armature generate current which is conveyed by flexible conducting wires to two corresponding pairs of binding posts on the top of the machine; thus, there are two independent sets of terminals from which two independent sets of mains may be run to the lights. Each set of mains thus has an armature coil by itself, feeding the current into it, and each armature coil has an independent circuit to act upon.

The machine illustrated is built in sizes ranging from 10 to 200 16 c. p. lamps. The company also manufacture the Chapman motor, of the consequent pole type with Siemens armature, and ranging from ¼ to 4 horse-power.

WESTERN UNION POLES.

The greater portion of the cedar telegraph poles used by the Western Union company come from Michigan. From forty to two hundred men and nearly forty teams are employed in gathering the poles and putting them in proper shape. The poles range from 26 to 60 feet in length, and are worth from $1 to $7 each.

TRUSTS AND THE LAW.

BY C. A. BROWN.

THE present tendency of public sentiment is strongly against Trusts, as are called combinations of corporations entered into for the purpose of controlling business and prices, and we may assume that unless public sentiment changes, or the incentive which induces these combinations fail, some method will be found, if necessary by alteration of the fundamental law to restrain and govern them, provided the legal means to accomplish this do not now exist.

Our inquiry now, therefore, is directed to ascertaining the extent and the principles upon which the law as it at present exists, prohibits private corporations organized for business purposes from entering into combinations with a view to controlling business and prices.

Corporations have the same legal limitations as individuals, and in addition thereto some which arise from their special nature and from the law to which they owe their creation.

We will examine then the prohibition which the law imposes upon individuals to prevent their combining to control business and prices, and then the additional disabilities of corporations.

The offences of engrossing, forestalling and regrating, defined and forbidden by the statute of 5 and 6 Edward VI, cap. 14, are now obsolete, and are merely worth mentioning as showing how changing conditions of life and trade modify the laws. Whether these offences were crimes at common law has been disputed. It is probable that they were not, but were made crimes by statute in the reign of Edward the Sixth.

It is a well settled rule of law that contracts in general restraint of trade are illegal and void (which means that a contract by which one of the parties has unduly restrained himself from following a trade or business, will be declared illegal).

The foundation of this rule lies in the advantage to the community of having every person at liberty to employ himself in that department of labor in which his personal efforts will be likely to add most to the aggregate productions of the country, and "that all the various trades and employments of society should be employed each in its due proportion,—a result with which the exclusion of any individual from his accustomed pursuits has a tendency to interfere." (Lawrence *vs.* Kidder, 10 Barb. 641.)

Originating as it did "when trade and the mechanical arts were in their infancy, and it was deemed a matter of the greatest public importance to encourage their growth, and to prohibit contracts which tended to abridge them" (Wright *vs.* Ryder, 36 Cal. 342), this rule has been modified, and seems likely to disappear practically in great trade centres. A convenient method of softening the asperity of this rule, lies in the distinction which is drawn between a contract in general and one in partial restraint of trade. The latter will be upheld by the courts under proper circumstances, and there seems to be a disposition on the part of the courts to restrict more and more the application of the doctrine, by extending more and more the limits within which a contract in restraint of trade will be considered partial. In the case of Diamond Match Co. *vs.* Roeber, 106 N. Y. 473, the New York Court of Appeals upheld a contract in which the defendant had agreed to refrain from competing with the plaintiff in a certain line of business in all the States and Territories of the United States, *except Nevada and Montana;* and decided also that the motive for the restraining agreement is not a test of its validity, since "a party may legally purchase the trade and business of another for the very purpose of preventing competition, and the validity of the contract, if supported by a consideration, will depend upon its reasonableness as between the parties." The application of this rule to agreements between several producing establishments by which one or more of them agrees to refrain from further production, is obvious, and it should be observed that the court in the case of Diamond Match Co. *vs.* Roeber, *supra*, says "that combinations between producers to limit production and to enhance prices, are or may be unlawful, but they stand on a different footing." The distinction being evidently in the purpose of the combination. If innocent and not prejudicial to public interests it will be sustained.

But in spite of the development of judicial opinion on the subject of contracts in restraint of trade, the cases, ancient and modern, agree that a combination, the tendency of which is to prevent general competition and to control prices, is detrimental to the public, and consequently unlawful. It should be observed that the question as to the legality of a contract in restraint of trade, arises solely between the parties to the contract; on application of one of them the court declares the contract invalid. Consequently combinations based upon such agreements depend for their continued existence upon the insecure tenure of the will of the parties, and the harmony of their relations.

Another question which has a bearing upon the agreements of producing persons and concerns to combine for the control of business and prices, is as to the legality at common law of a joint stock company without legislative sanction, with transferable shares. Such an association, which is in fact a partnership, would seem to be legal unless it can be shown to have a purpose which is not legitimate, although a contrary conclusion has been reached in Illinois and Louisiana. The following is the substance of the propositions of Mr. Lindley on this subject in his work on Partnership:—That it is not illegal for any number of persons to enter into a contract of partnership, nor for them to agree that when one retires a person who is not a member of the firm, but who is willing to become one, shall take his place; nor that the new comer may be selected by the one retiring; nor that the outgoing and incoming partner may agree upon the terms of withdrawal and entrance, if these terms are not in themselves illegal; nor is it illegal for the members of a firm to assume a name, and to agree that the management of its affairs shall be entrusted to a select few, and that these select few shall have power to make rules which others shall be bound to obey.

It would seem, therefore, that objections to associations formed under a trust agreement, such as that under which the Sugar Trust operates, on the ground that they usurp the functions of a corporation, are not well founded. To be open to this objection there must be an assumption of the qualities of a legal person as, for example, to sue or to be sued in a corporate name. Avoiding this usurpation of corporate power the legality of such an association depends upon the legality of its object. If its object is to keep the supply steady and adequate to public wants, to avoid overproduction, to promote economy of administration and reduce the cost of operating, it is innocent and for the best interests of the public, and therefore legal. But if, on the other hand, the object of such an association, express, or implied, is to create a monopoly and enhance prices, it is against public policy and illegal.

In considering this question with reference to the special limitations imposed upon corporations, it is desirable to glance briefly at the salient features of the nature of a corporation having a bearing on this subject.

"A corporation is a body consisting of one or more natural persons, empowered by law to act as an individual and continued by a succession of members."

A corporation owes its franchise to the sovereign power (in this country, the legislature), or to prescription which pre-supposes a grant from such power.

There are two methods in which corporations are created: first, by specific grant of the franchise to the members; second, by a general grant which becomes available for particular persons when they organize themselves in accordance with the provisions of the grant.

The following powers and privileges are said to pertain to all corporations:—First, the power of perpetual succession of members; second, the power to sue and to be sued in the corporate name, and to transact in that name all such business as is within the intent of the grant; third, to purchase, take and hold property, and to sell and convey the same except as may be forbidden; fourth, to have a common seal under which to transact its business, and to alter the same at pleasure; fifth, to make by-laws for its government, provided they be not unreasonable or inconsistent with law.

In this country corporations are created by state legislatures alone, except that the Federal Government may create them in the Territories and the District of Columbia, though even in this restricted territory the general government does not usually assume the prerogative, but leaves the creation of corporations to the local legislature, when there is one. Strictly speaking, corporations exist only in the state in which they are formed, but the principle of comity between the states has modified the strictness of this rule, and practically permits to corporations the full exercise of power in other states which they may exercise lawfully within the state in which they have received their charter. This comity, however, is limited necessarily. In all cases any general policy of the state, into which a foreign corporation comes to do business, must limit the requirements of the comity.

A corporation is obliged to confine its operations to the sphere of the authority conferred upon it by the legislature. Acts beyond this are *ultra vires*. Thus, one corporation cannot consolidate itself with another, unless by express authority of the law, and the directors of a company cannot dispose of its franchises, and thus wind up the corporation, for the directors are elected to continue the corporation, not to destroy it.

The granting of a charter by a legislature and the acceptance of it by the incorporators, constitute a contract which is inviolable. This fact has led to provisions in constitutions making a charter subject to alteration, amendment and repeal, at the will of the legislature. Unless this right is reserved by the constitution, or in the general or special incorporation act, the legislature has no right to alter, amend or repeal the charter of a corporation. Whether its charter is amendable or not, it is subject to the general police powers of the state.

Although corporations are said to be immortal, their existence may be brought to an end. First, when the corporation is limited by its charter to a certain period of time, and that period has elapsed; second, when right to repeal its charter is reserved, and in accordance with this right the charter is repealed; third, the company may voluntarily surrender its franchises; fourth, a corporation may cease to exist by forfeiture of its franchise. This forfeiture can only be worked through the raising of the question by the state. These are practically all the methods which need be considered.

Foremost amongst the principles limiting the power of corporations to combine for the control of business and prices, is that stated by Chief Justice Savage, in the Fulton Bank case, as follows:—"They (corporations) have no powers but such as are granted, and such as are necessarily incident to the grant made to them. Corporations at common law have certain powers, but not such as would authorize the forming of a partnership or the consolidation of two corporations into one." The legal penalty for transgression of this rule would be the forfeiture of its charter and dissolution of the corporation. "A corporation may incur a forfeiture of its franchises by the doing of an illegal act. Any act of a corporation which is forbidden by its charter, or by a general rule of the law, and, strictly, every act which the charter does not expressly or impliedly authorize the corporation to perform, is unlawful; and if the doing of such act is an injury to the public, it may be sufficient ground for declaring a forfeiture of the corporate franchises." (2 Mor. Priv. Corporations Section 1024.)

Hence it appears that a corporation has not the authority to enter into any partnership arrangement, even though such partnership arrangement would have been lawful between individuals.

In order to escape the consequences which follow such unauthorized combinations on the part of corporations, the form of Trust Agreement, of which that forming the Sugar Trust is a representative, has been devised. Taken in their order the principal features of this deed are: first, statement of the objects; second, agreement of the parties to the deed, in the first place, to organize corporations of such separate organizations as are partnerships, and in the second place, to surrender corporate shares to a board of eleven persons having certain powers; fourth, that the stockholders surrendering their stock shall receive in lieu thereof certificates signed by the board; fifth, division of the profits proportionately among the holders of the board certificates.

The question arises whether such an instrument as this, purporting as it does to be an expression of the act of the stockholders as individuals, is really such in law, or is in law what it is in purpose, an agreement of the corporations. In the discussion of this question, in the opinion of Barrett, J., in the case of The People *vs.* North River Sugar Refining Co., he says: "We now come to the legal question, is this a combination of corporations, or merely a combination of stockholders? The defendant claims that unless authority to sign the trust deed, given by the directors of each corporation at a regular board meeting, is affirmatively proved, the acts complained of are not corporate acts. * * * * . * * The accumulation of evidence points irresistibly to the complete practical identity of shareholders and corporations, and it is quite impossible to sever the acts of the persons solely interested in these corporations from those of the corporations themselves. The purpose to effect corporate combination cannot be disguised. * *"

"A corporation, or a body politic, or a body incorporate," says Mr. Kyd, "is a collection of many individuals united into one body, under a special denomination, having perpetual succession under an artificial form, and vested by the policy of the law with capacity of acting in several respects as an individual." It is really an association of persons, and the word "corporation" is but a collective name for the corporators or members. (1 Mor. Priv. Corp. No. 1, 227,474.) The shareholders vested with the corporate powers are the body corporate, corporation or company. (Taylor Corporation Section 50.) * * * * Mr. Morawetz puts it clearly when he says that "while a corporation may from one point of view, be considered as an entity without regard to the corporators who compose it, the fact remains self-evident that a corporation is not in reality a person or a thing distinct from its constituent parts, and so the acts of the collection body are the acts of the corporation, and if unlawful will work a forfeiture."

"When the whole body of stockholders offend the law of the corporate being, the corporation offends. * * The directors are but the agents of the corporation to manage its affairs, and carry out the purpose and object of its formation. They are only authorized to do such things as are directly or impliedly directed or authorized by the charter. The directors of this defendant could not have bound the corporation by the deed in question. That deed involved momentous changes in the life and destiny of the corporation, and in the relations of its shareholders, which were entirely foreign to the general management of its business."

If it be concluded that agreements such as the one under consideration are corporate agreements, they come within the rule which prohibits such partnership arrangements on the part of corporations, and the legality of such combinations need not be further considered.

But another method by which the same result is endeavored to be reached, is the purchase by one corporation of the capital stock of other corporations. A representative instance of this method is that of the Chicago Gas Trust Company, which was considered by the Supreme Court of Illinois in the case of The People *ex rel.* Peabody *vs.* Chicago Gas Trust Co.

The Chicago Gas Trust Company was organized under the general incorporation law of the State of Illinois, and its object as appears in the statement filed with the Secretary of State, was: first, the erection and operation of works in Chicago, and other places in Illinois, for the manufacture, sale and distribution of gas and electricity; second, to purchase and hold or sell the capital stock of any gas or electric company or companies in Chicago, or elsewhere in Illinois.

In the decision of the Supreme Court of Illinois, Magruder J. says: "There are two views which may be taken of the power to purchase and hold the capital stock of other gas companies as designated in said second clause. Must it be regarded as an original, independent power, intended to exist exclusively and in addition to the power named in the first clause, or may it be considered as merely ancillary to the other power of maintaining and operating works for the manufacture and sale of gas? If the latter view be correct, the main object for which the Gas Trust Company was formed would be that it might itself maintain and operate works for the manufacture and sale of gas, while the purchase of shares of stock in other companies would be merely a subordinate object, incidental only to the main purpose of the corporate formation. * *

Can the power to purchase and hold the stock of other gas companies be lawfully exercised by the appellee as incidental to the main purpose of maintaining and operating works for the manufacture and sale of gas? Corporations can only exercise such powers as may be conferred by the legislative body creating them, either in express terms or by necessary implication; and the implied powers are presumed to exist to enable such bodies to carry out the express powers granted, and to accomplish the purposes of their creation. * * * * * *

An incidental power is one that is directly and immediately appropriate to the execution of the specific power granted, and not one that has a slight or remote relation to it. * * * * * * *

Where a charter in express terms confers upon a corporation the power to maintain and operate works for the manufacture and sale of gas, it is not a necessary implication therefrom that the power to purchase stock in other gas companies should also exist. "The right of a corporation to invest in shares of another company cannot be implied, because both companies are engaged in a similar kind of business." (1 Mor. Priv. Corp. Section 431.) * *

If, then, the power to purchase outside stocks cannot be implied from the power to operate gas works, and make and sell gas, a company to whom the latter power has been expressly granted cannot exercise the former without legislative authority to do so. This is the law as settled by the great weight of authority. Boone on the Law of Corporations, says: "Without a power specifically granted or necessarily implied, a corporation cannot become a stockholder in another corporation, and especially where the object is to obtain the control or affect the management of the latter."

"In Green's Brice's Ultra Vires it is said: 'In the United States a corporation cannot become a stockholder in another corporation unless by power specifically granted by its charter, or necessarily implied in it." So also 1 Mor. Priv. Corp. (sections 431 and 433) says: "A corporation has no implied right to hold stock in another company for the purpose of controlling its management. * * * A corporation cannot, in the absence of express statutory authority become an incorporator by subscribing for share in a new corporation, nor can it do this indirectly through persons acting as its agents or tools." The authorities referred to by these text writers sustain the conclusions announced by them. It has been held in many cases that, "in the United States corporations cannot purchase, nor hold, nor deal in the stocks of other corporations unless expressly authorized to do so by law;" and that, "one corporation cannot become the owner of any portion of the capital stock of another corporation, unless authority to become such is clearly conferred by statute.'

* * * * * * * *

"The power to purchase and hold stock in other companies must be the subject of legislative grant, if not in all cases, at least in cases where it cannot be implied from the powers expressly granted. The general incorporation law contains no grant of such power by the legislature. Can a corporation organized under that law be clothed with such a power by merely naming it in the statement filed with the Secretary of State? We think not.

* * * * * * * *

"We come now to the second view of the right to purchase and hold the stock of other companies. * * * Both were designed to be of equal importance, and to be carried out independently of each other.

* * * * * * * *

"Manufacturing and selling gas is one kind of business; dealing in stocks is another and different kind of business. If it appeared that the appellee was engaged in both under its present charter a serious question of fact arises as to the power to organize one corporation for two distinct purposes under the general incorporation act of this state.

* * * * * * * *

"The general incorporation act provides "that corporations may be formed in the manner provided in this act for any lawful purpose, except banking, insurance, real estate, brokerage, the operation of railroads, and the business of loaning money." The purpose for which a corporation is formed under the act, must be a lawful purpose. So far as appellee was organized with the object of purchasing and holding all the shares of the capital stock of any gas companies in Chicago or Illinois, it was not organized for a lawful purpose, and all acts done by it towards the accomplishment of such object, are illegal and void."

Another limitation to the power of private corporations to combine is thus stated by Justice Miller in Thomas *vs.* The Railroad Co., 101 U. S. 71:

"When a corporation, like a railroad company, has granted to it by charter a franchise intended in large measure to be exercised for the public good, the due performance of these functions being the consideration of the public grant, any contract which disables the corporation from performing these functions, which undertakes, without the consent of the state, to transfer to others the rights and powers conferred by the charter, and to relieve the grantees of the burdens which it imposes, is a violation of the contract with the state, and is void as against public policy."

So that unless expressly authorized to do so a corporation which owes a duty to the public cannot lease or transfer its franchises, nor mortgage them, nor consolidate with another company. In the case of a consolidation, by which is meant the formation of one corporation by the shareholders of several corporations, and the dissolution of the latter, it is important to inquire what may be the effect of this act on the property rights and liabilities, both of the original companies and of the corporation resulting from the consolidation.

As associations of private corporations can only take place when authorized by statute, it follows that the effect of a consolidation is controlled by the statute under which it takes place. Usually the new corporation is invested with all the rights and franchises of the consolidating companies. The new corporation is also generally liable under the same obligations incurred by either of the consolidating companies.

Consolidations of corporations can be effected, therefore, without losing the rights and liabilities of the consolidating companies, when so authorized by statute and by the unanimous consent of the stockholders. A majority of the stockholders can effect a consolidation, provided the charters of the corporation, or any general law in force at the time when the corporation was formed, provides that the corporation may consolidate with other companies, such charter or such general law being considered to enter into the fundamental contract between the shareholders.

It follows that consolidations of corporations are limited to those companies existing in a single state. No such consolidation could be effected between corporations existing in different states.

Briefly, then, it is not a criminal offence at common law for persons or corporations to combine to control business and prices.

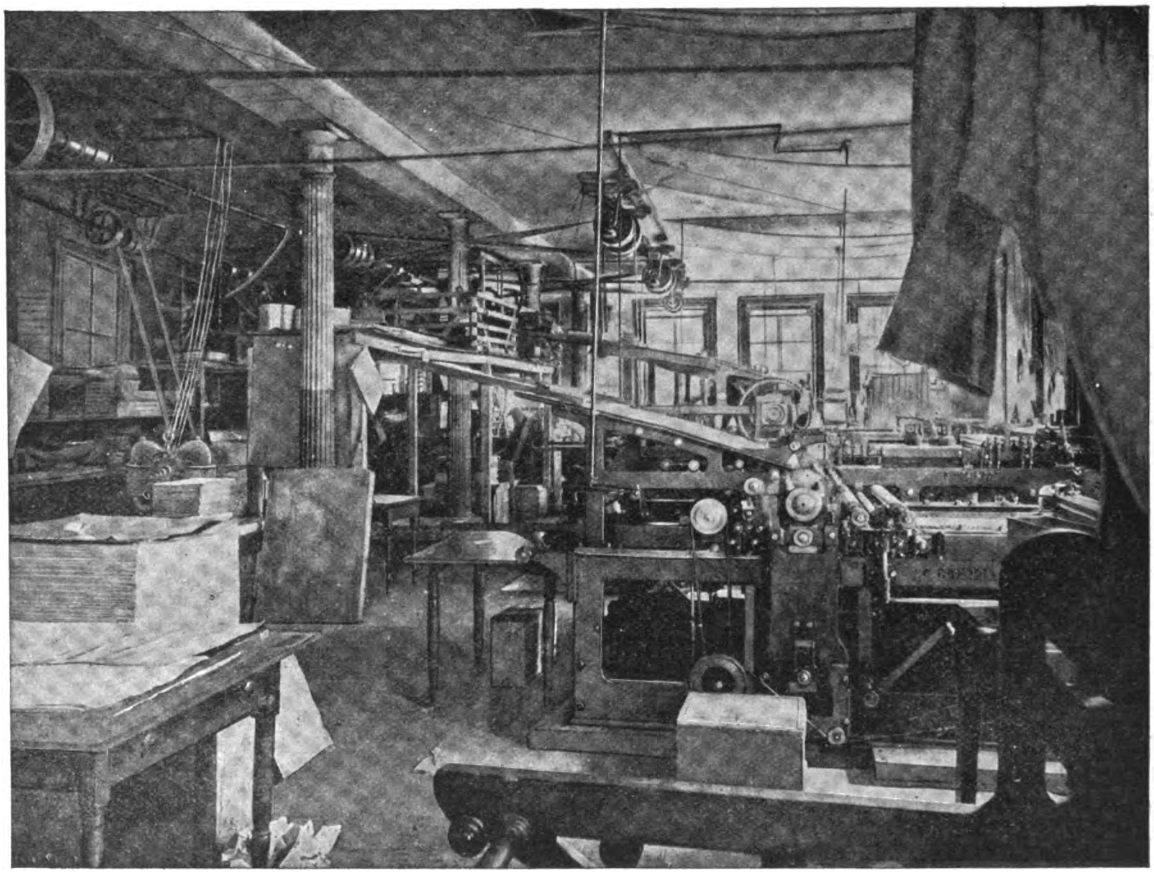
Contracts in general restraint of trade are void, and will not be enforced by the courts.

Joint stock companies are legal if their objects are so.

A corporation must confine its operations to the sphere of authority conferred upon it by the legislature. It can not consolidate with another, nor dispose of its franchises, and thus dissolve, except by express authority of law.

A corporation cannot enter into a partnership unless expressly authorized to do so, and an agreement of all the stockholders of one corporation with all the stockholders of another corporation, such as that which forms the basis of the Sugar Trust, is legally the same as the agreement of the corporations, and renders the charters of the corporations liable to forfeiture.

A corporation cannot legally purchase and hold the capital stock of another corporation in order to obtain the control or affect the management of the latter.



Electric Motor in a Bank Note Printing House.

A corporation which has a public duty to discharge is bound not to part with or encumber its franchises.

Consolidations of corporations can be effected when authorized by statute, and must be accomplished in accordance with the direction of the statute.

The courts hold corporations strictly under the control of the state in the management of their business, unless by the elements of contract in their charters they are released in a measure from such accountability.

Certainly there is no law which compels the people to submit to spoliation on the part of corporate bodies which the people acting in their law-making capacity have brought into existence.

ELECTRIC MOTORS FOR PRINTING BANK NOTES.

It is well known to printers that the highest class work in engraving and printing requires a power which is at once steady, reliable and under prompt control. The presses must run with perfect regularity, and at constant speed, and to supply these conditions electric motor power stands unrivaled. Sprague electric motors, from their ability to keep the speed constant under varying loads, have long been used for these classes of work where such sort of service is a desideratum.

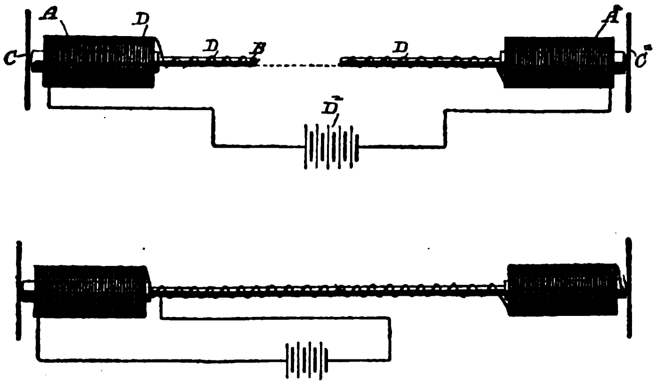
In this issue we illustrate the press rooms of the Boston Bank Note and Lithograph Company, in which all the power used is supplied by a 10 h. p. electric motor. This is belted directly to the line of shafting extending the length of the room, from which are run the presses, folders, cutters, and other machinery used. Only a part of the presses used is shown in the view, the shafting extending a considerable distance beyond the limits of the engraving.

It is interesting to note in this installation the relatively small size of the electric motor compared with the amount of machinery kept in motion. A steam engine of this power would require from ten to fifteen times as much space, without counting the room required for boiler, etc. The motor occupies a space of less than eighteen cubic feet. There are now about twenty Sprague motors used in the city of Boston for operating presses alone, while the total number is in the neighborhood of two hundred.

VOGEL'S METHOD OF TELEPHONIC TRANSMISSION.

THERE has recently been brought out in Chicago a system of telephonic transmission invented by Mr. William Vogel, which embodies a new application of the line wire to effect an increase in the efficiency of transmission. This is accomplished by maintaining the iron or steel conductor in a magnetic state, by which the effect of the vibrating armature of the transmitting telephone is propagated magnetically as well as electrically. The accompanying engraving, Fig. 1, shows one method devised to carry out the idea, in which a soft iron wire, B, has a conductor, D, wound spirally around it, and connected with a battery, D′, so as to form poles at the extremity of the wire. Each pole piece and diaphragm serves either as transmitter and receiver, the transmissions being effected by the change in the magnetic condition set up in the iron wire, B.

The diagram, Fig. 2, shows another method of carrying out the idea, one in which the iron wire constituting the magnetic circuit is also made part of the electric circuit. This has been carried out practically in an apparatus illustrated in Fig. 3, and in enlarged view in Fig. 4. Here the pole-pieces, P P′, are connected by a core wire.



FIGS. 1 AND 2.—VOGEL'S TELEPHONE SYSTEM.

R R is an electric conductor connected with the battery, *r*, and wrapped about the core-wire and pole-pieces, P P′. The extreme end of the pole-pieces of the conductor, R, is wound in a manner to form a thick coil or bundle of wires, R′, and the ends of the conductor are connected with the pole-pieces, as indicated at *r*′. S S′ are electric conductors which surround the pole-pieces, and which are in circuit with local batteries, *s s*′. The current flowing through the conductors, S S′, serves to re-enforce or strengthen the poles of the magnet.

INVESTIGATION OF STANLEY ALTERNATE CURRENT ARC DYNAMO.

THE graduating thesis of Messrs. Tobey and Walbridge[1] embodies an experimental investigation of the new Stanley alternate current arc machine. The general method was to obtain instantaneous values of electromotive force and current at a sufficient number of points to indicate by curves the performance of the machine at every part of a revolution. For this purpose a condenser was charged by a suitable commutating device to the potential it was desired to measure, and then discharged through a ballistic galvanometer. Readings of arc and field current were taken by fall of potential method.

The E. M. F. curve exhibited a very peculiar form, approximating more nearly to a rectangle than to a sine curve. The reversal of direction was very abrupt, the E. M. F. at a load of 20 lamps changing during 3.8° from 960 volts positive to 1,560 negative, making a total of 2,520 volts. This effect is due to the action of the arc, for when the machine worked on non-inductive resistance (incandescent lamps), the curve of E. M. F. approximated quite closely to a sine curve. The arc current in all cases approximated to a sine curve, and the field current exhibited a wiry form, the maxima of this and the arc current curves corresponding.

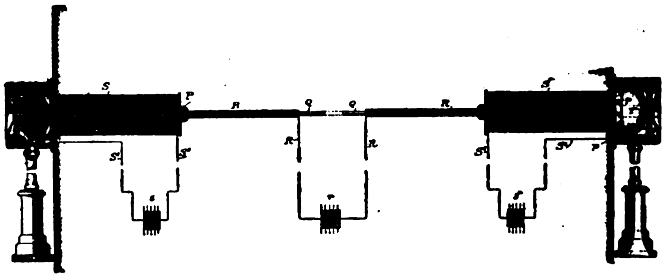


FIG. 3.—VOGEL'S TELEPHONE SYSTEM.

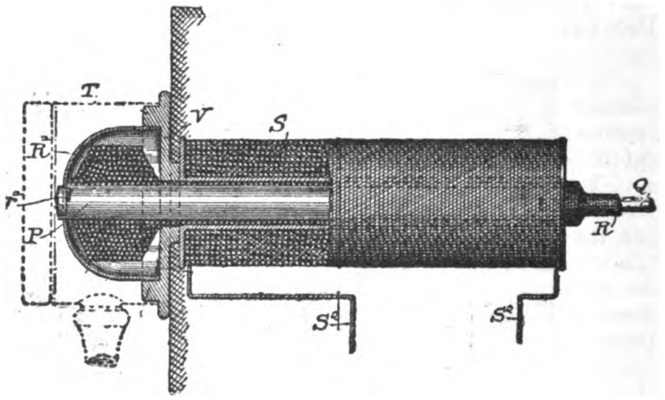

FIG. 4.—VOGEL'S TELEPHONE SYSTEM.

The current lag in all cases was very small, increasing slightly as the load increased. The zeros of both E. M. F. and current moved backward slowly with reference to the pole pieces, as the load became greater.

Owing to the non-arrival of part of the lamps the test has not as yet been completed, but for all runs yet taken for over half load, the machine showed an efficiency of over 90%.

THE EFFECT OF ELECTRICITY ON THE COEFFICIENT OF FRICTION.[1]

BY M. LEVY.

ON account of the variance of opinion of the several experimenters in this line of investigation, the writer has applied himself to obtaining such data as will definitely answer questions directly connected with this subject.

The apparatus used in these experiments consisted in main of an iron plate resting in a perfectly horizontal position on the periphery of three cast iron wheels, the latter restricted to turning except in one direction. If not prevented the plate would therefore take up the same direction and rate of motion as the point at the periphery of the wheel in contact with the plate. This tendency of the plate to move, caused solely by the friction between the wheel and plate, is measured by suitable apparatus provided therefor. Proper measurements were taken when currents varying from zero to 47 amperes passed between the surface of contact of the wheels and plate.

With perfectly clean and dry surfaces of contact and about 45 amperes passing therethrough, an increase in the coefficient of friction amounting to about 119% was observed.

---

[1] Sibley Coll., Cornell Univ.

[1] Abstract of Graduating Thesis, Sibley Coll., Cornell Univ.

When the surfaces of contact were bathed in oil 40 amperes increased the coefficient of friction by almost 103%. With a thin coating of oil 47 amperes increased the coefficient 133%. Up to 41 amperes water seemed to prevent the above observed effect of the current.

A current of 40 amperes through the surface of contact of wheels and plate corresponds to a current-density of no less than 5000 amperes per square inch.

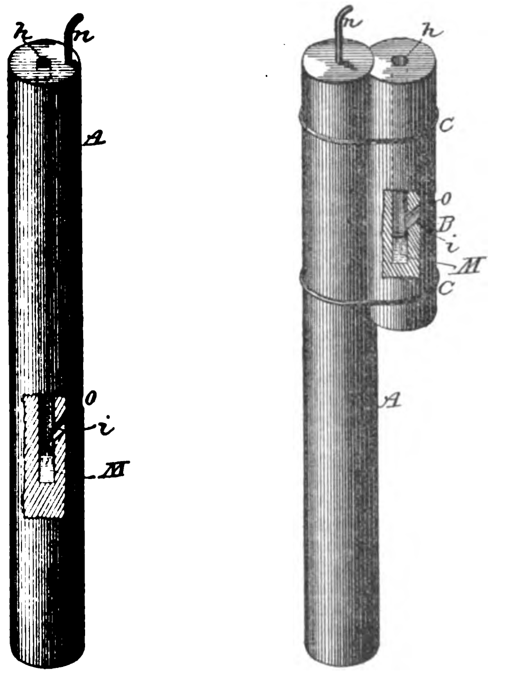
The above are among the most important results obtained in these experiments.

WILLIAMS' SELF-AMALGAMATING ZINC.

The usual method of amalgamating battery-zincs is by immersing them in a suitable acid mixture to clean their surfaces, and then spreading mercury over the surfaces which have been cleaned by the action of the acid mixture. The film of mercury on the zincs gradually disappears during the action of the cells and must be renewed by re-amalgamating or by keeping a quantity of mercury in contact with the zincs, usually in the bottom of the cells in which the zincs stand.

To avoid the trouble of frequent re-amalgamation, Dr. James B. Williams, of this city, has recently designed and patented a zinc which is self-amalgamating, and which is accomplished without removing the zincs from the cells.

The accompanying illustrations give a clear idea of the method employed by Dr. Williams as applied in the case of the plain cylindrical zinc, or in the shape of an attachment secured to the same. The cavity containing mercury M is formed entirely in the substance of the zinc, or in a body B having any suitable shape and size, which can be securely fastened to the zinc by wires C C, which are protected from the action of the battery solution by covering them with suitable compositions. From near the bottom of the cavity a canal *i* runs obliquely in an upward direction, and its opening *o* is on a portion of the surface of the zinc which is below the level of the battery solution. Another canal *h* runs in an upward direction and terminates on a portion of the surface of the zinc which is outside the battery solution. The purpose of the canal *i* is to allow the battery solution to have access to the mercury in the bottom of the cavity, and that of the canal *h* to allow mercury to be poured into the cavity without removing the zinc from its cell. The cavity and its outlets are formed in the zinc during the process of casting or by drilling.

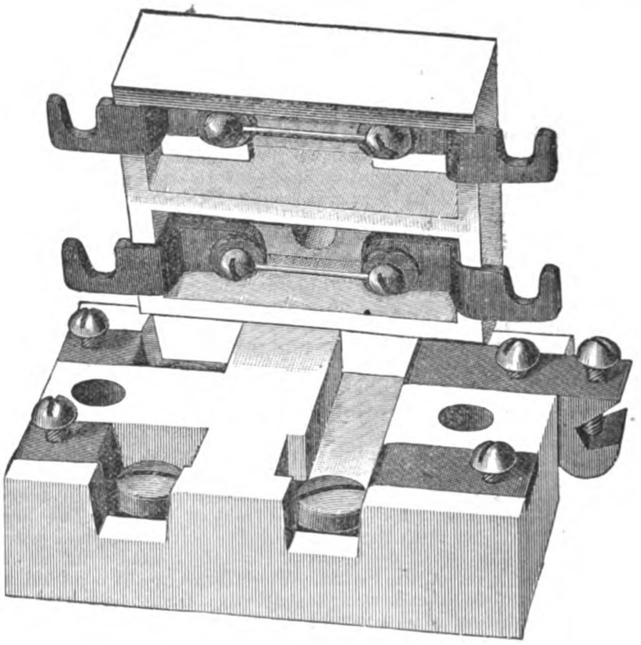


Figs. 1 and 2.—Williams' Self-Amalgamating Zinc.

To prepare the zincs for use, they are first amalgamated in the usual manner, a quantity of mercury placed in the cavities, and the zincs placed in their cells. If the zinc bodies are used, they are first fastened to their zincs and amalgamated with them in the usual manner, and a quantity of mercury placed in their cavities, after which they are placed in their cells. The mercury is renewed from time to time, as the film of mercury on the zincs is removed during the action of the battery. The zincs continue to be self-amalgamating until the zinc is dissolved to such an extent that the cavity will no longer retain the mercury which is poured through the canal *h*.

AN IMPROVEMENT IN DOUBLE POLE CUT-OUTS.

In the handsome new catalogue of electrical appliances recently issued by the E. P. Gleason Mfg. Co., we find illustrated a new design of porcelain double pole cut-outs. This cut-out, as shown in the accompanying illustration, differs from those heretofore employed, in that the fuses are carried by an adjustable cover. By means of this arrangement they can be readily inspected and removed when necessary without disturbing any of the circuit wires. The fuses, it will be seen, are connected to two pairs of lugs which pass under corresponding screws on the base; thus the act of screwing down the lid automatically makes the proper connection. These cut-outs are made in a variety of sizes and designs, and are of excellent construction.



Improvement in Double Pole Cut-Outs.

POSTAL TELEGRAPHS.

The House Committee on Post Office and Post Roads adopted a resolution last week offered by Representative Blount of Georgia, providing that the consideration of the Postal Telegraph bill now before the committee be postponed until the next session of Congress. The resolution also gives the sub-committee having charge of the subject authority to notify all parties interested that any written statements they may desire to present on the matter should be submitted to the committee within the next thirty days.

THE ELECTRICAL EXHIBITS AT THE PARIS EXPOSITION.

BY CARL HERING.[1]

PRIMARY BATTERIES.

BICHROMATE OF POTASH CELLS AND THEIR MODIFICATIONS.

(Concluded.)

M. Gustave Trouvé (French section. Gold medal) had an elaborate exhibit of primary batteries, chiefly for medical purposes and small lights and powers. They are almost all of the ordinary carbon, zinc and bichromate type, and leave little to be described. The small portable and pocket cells for medical and surgical purposes, and for small lights, are arranged in convenient form, as regards plunging of the plates and prevention of spilling the acids. A small portable lamp battery has loose ribs around it like those of an umbrella, which ordinarily are not noticeable, but if the cells should start to fall over, these ribs spread out and prevent it from falling. M. Trouvé exhibited also a small boat run by an ordinary plunge battery. Apparently the only novelty is that the motor and propeller are on the rudder and are geared together by a chain gearing.

M. Trouvé uses a more concentrated solution than usual; his proportions (by weight) are: 1 part bichromate of potash, 8 parts water and 3.6 parts sulphuric acid. The constants of the cells for the boat are: 1.9 volt, .07 to .08 ohm internal resistance; 4 cells will develop 14 kilogrammetres per second for two hours running before it falls.

Most of the batteries exhibited using bichromate of potash for depolarizer, have the zinc in a porous cup in dilute sulphuric acid. Among the principal modifications were the following:

M. Crosse (French section. Honorable mention) replaces the usual carbon plate by a sort of cage of thin sheet lead, perforated, and filled with fragments of retort carbon. The lead acts merely as a receptacle and a conductor for the carbon. The lead cage is made of two concentric cylinders united at the top and bottom, the annular space between them being filled with the carbon fragments. A lead terminal leads off the current. He claims as the advantages, that it is not fragile like carbon plates; it is cheaper; it offers great surface of carbon, lowering the resistance, diminishing the polarization and thereby increasing the rate of discharge; it overcomes the objection to the unreliable brass terminal secured to the carbon plate. A one pint cell costing 50 cts. is said to have a capacity of 30 ampere hours, at a rate of from 1 to 5 amperes. A one gallon cell costing $3.00 has a capacity of 250 to 300 ampere hours at a rate of 6 to 20 amperes.

Overflow Tube.—The following simple and ingenious overflow tube was used in a number of different batteries of this class. The liquid, in such cells, after it has performed its function, is heavier and sinks to the bottom. In adding new liquid to the old, the overflow of the old liquid should be from the bottom of the cell. This is effected by means of a vertical glass tube outside of the cell, the upper end of which tube is bent around in a semicircle forming a nozzle for the liquid to flow out of. The lower end communicates with the inside of the cell through a hole in the bottom. The top curved part of the tube must be just as high as the normal level of the liquid. When fresh liquid is added, the old will therefore overflow automatically from the bottom. If this tube is connected by a flexible rubber tube the cell can readily be emptied by bending down this tube.

Mr. G. U. Lagarde (French section. Bronze medal) exhibited a battery for lighting purposes in which the carbons were revolved continually by an electric motor to agitate the liquid. The cells were arranged in a circle; the fresh liquid was supplied from a tank in and over the middle, the supply cock being opened electrically when the potential had fallen sufficiently. The zincs are perforated. The following data is given by the maker: Price of liquid, 4 cts. per quart; one quart will run a 5 candle-power lamp for 1 hour. The price of the zinc, 40 cts.; the set of twelve zincs will run 240 ampere hours; a battery of 12 cells gives 15 to 18 volts and 8 to 10 amperes, and costs $100.

In the battery of M. Pillet (French section), instead of raising and lowering the zincs, the liquid is lowered and raised respectively, by air pressure produced by a rubber bulb simultaneously on all the cells.

In the medical battery of Chardin (French section) this same principle is used to great advantage, making a clean, practically sealed, cell, very well adapted for physicians and surgeons. The retaining cell is of porcelain and consists of two parts; the upper one, containing the electrodes, is empty when not in use. The lower one is closed completely and contains the liquid. A tube communicates from the lower part of the upper to the lower part of the lower cell. By pumping air into the lower one, which is readily done by means of a rubber bulb, the liquid is forced up through this tube into the upper cell; by allowing this air to escape, the upper cell is drained.

In the Bazin battery for lighting, the carbon plates are in the form of circular disks mounted on a common shaft which is revolved by a small electric motor; the revolving of the plates is claimed to diminish the polarization. In the curves of discharge exhibited, the difference of potential of 1 volt for currents of 9 to 10 amperes is shown to be remarkably constant for 40 to 50 hours' continuous discharge.

In the battery of Kornfeld (Russian section) the cells are very narrow, deep, rectangular boxes made of carbon plates cemented in some way at the edges, and heavily copper-plated on the outside. The box forms the positive pole; the zinc plate is lowered down into the box when in use, and is very close to the carbon on all sides, thus making the internal resistance very low. Liquid is supplied continually at the top and is led out at the bottom in the usual way. The whole battery is very compact.

In the Chameroy (French section) battery, the cell itself is of a tube of carbon, the zinc being a concentric rod secured at the top and bottom. The liquid enters continually at the top and is led out at the bottom. The zinc rod is cast in the form of a screw with a very coarse, deep thread, whereby the liquid is made to circulate in passing down.

In the cell of Radiguet (French section. Silver medal), the object is not only to lift the zinc out of its solution in the porous cup, when not in use, but also to empty this porous cup at the same time, to prevent diffusion of the liquids. To do this, there are two cups at right angles to each other, joined at their open end like the letter L inverted, and turning on a horizontal axis through this point, and over one edge of the jar. One is porous and swings in and out of the jar, and the other is glazed and is outside. The zinc is placed in the porous one. To immerse the zinc, its porous cup is turned vertically so as to be in the jar, and the liquid from the glazed cup flows into it. To withdraw the zinc, the two cups are rotated through a right angle which empties one into the other. In another cell of the same exhibitor, instead of using a zinc plate for the negative pole, he uses a copper tray or basket well amalgamated, filled with scraps of zinc and some mercury. The copper tray acts merely as a conductor, and is not attached, if well amalgamated. The object is to use up scrap zinc.

In the Delaurier cell exhibited by Guérot (French section. Honorable mention), designed chiefly for electroplating, and consisting of zinc, carbon and porous cup, the liquid used with the carbon is made of 87 parts ferro-chromic salt, 198 pts. warm water, and 155 pts. sulphuric acid. The liquid for the zinc is water with a little of this added. The zinc need not be amalgamated. The chief advantage is cheapness.

Residues.—Among other exhibits properly belonging here was an interesting one of Mr. George Fournier (French section. Bronze medal), which may prove of importance in cheapening bichromate batteries by finding a market for the residues of these batteries. The exhibit comprised the various commercial products obtained from these residues. His process of separating the residue into commercial products is briefly as follows: The residue coming from the batteries is a mixture of sulphate of chromium, sulphate of zinc, sulphate of potassium or sodium, sulphuric acid, chromic acid and water. The first process is to neutralize the free acid by means of scraps of metallic zinc This is finished when the solution has become green instead of brown. During this process chrome alum crystallizes out, forming one of the commercial products, being used chiefly as a mordant. The oxide of chromium is then separated by precipitation at 212° F., by adding fragments of zinc, or by oxide of zinc at ordinary temperatures. This is finished when the solution has become quite clear. This oxide of chromium is the second commercial product. The remaining solution is treated with chalk which precipitates zinc oxide together with sulphate of calcium. This is finished when the liquid does not become turbid when ammonia is added. The remaining liquid contains only sulphate of potassium or sodium, or both, depending upon whether the bichromate of potassium or sodium was used in the battery. If only one of these was used, this liquid, evaporated to dryness, forms the third commercial product. To the mixture of oxide of zinc and sulphate of calcium, some sulphate of zinc is added until the solution is slightly acid in order to be sure that no chalk remains; bichromate of potash is then added, forming a bright yellow precipitate of chromate of zinc, which is an excellent pigment, and may be used for coloring paper, for paints, etc., having a great covering power owing to the sulphate of calcium mixed with it. From the chromium oxide are then made different colors, mordants, chromic acid, metallic chromium, and it may be used in the iron and steel industries.

OTHER BATTERIES FOR LARGE OUTPUT.

One of the most interesting of the battery exhibits was the Lalande & Chaperon cell exhibited by de Branville & Cie. (French section. Gold medal for collective exhibit.) It has gradually come into extended use, its numerous advantages giving it a very important place among batteries. It is a single fluid cell with a solid depolarizing substance. It can be used for open circuits, for closed circuits and for strong currents. The electrodes are amalgamated zinc and black oxide of copper; the liquid is caustic potash of 30 to 40 parts to the 100. The action is to dissolve the zinc and to reduce the copper oxide to metallic copper.

---

[1] Advance sheets of the report of the expert of the U. S. Commission to the Paris Exposition, Section "Electricity."

Erratum. On page 374, first column, sixth line from top, 56 cts. should read 56 *cent.*

Construction.—One of the principal forms, called the spiral form, is shown in the accompanying engraving, Fig. 3, in which D is the zinc spiral, and A is a thin sheet iron box containing the copper oxide B and a copper wire conductor C, insulated where it passes near the zinc. The cell is 7¼" high and 4¼" in diameter. Another form called the hermetic type, consists of a cast iron bottle forming the retaining cell and at the same time one pole, having the oxide of copper on the bottom. The zinc, suspended by an amalgamated brass rod, is held by the rubber stopper, which at the same time seals the cell. In the large hermetic type the zinc is in the form of a large flat spiral presenting great surface, and the cast iron bottle is closed by means of three bolts and a rubber gasket. In the trough form for heavy currents, the iron cell is in the form of a very shallow flat rectangular box; the layer of oxide of copper on the bottom is covered with a sheet of parchment paper, and the zinc is a flat sheet with a brass lug attached to it. The liquid is covered with a layer of some thick oil. When a number of these cells are to be used in series, as for incandescent lights, they may conveniently be placed one over the other. The size and style of cell depend on the purpose for which it is to be used; the large trough form (about 16" x 8" x 4") is designed chiefly for lighting, small powers, electrolysis, etc.

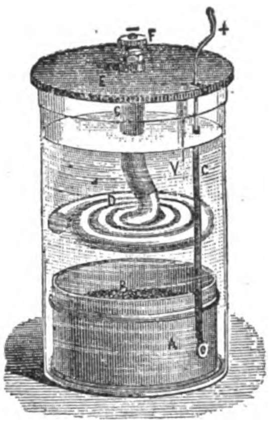


FIG. 3.

Constants.—The following constants of these cells may doubtless be relied upon as correct. The electromotive force on open circuit is from .8 to .9 volt. The following table gives some of the constants for continuous discharge, through an external resistance equal to the internal, that is, for maximum work, in which case, therefore, the difference of potential, or useful electromotive force is slightly less than half of that on open circuit.

	Internal resistance.	Amperes.	Capacity in ampere hours.
Spiral form	0.15	1.5–2.0	70
Hermetic form, small	0.15	0.5–0.7	15
" " medium	0.10	1.5–2.0	70
" " large	0.035	6. –8.	540
Trough form, small	0.10	3. –4.	235
" " large	0.35	6. –8.	540

See also the constants in the expert's reports given below.

Properties and Uses.—There being no great polarization, the cells can be used on closed circuits without any stirring or circulation of the liquid; the difference of potential on closed circuit is said to fall slightly at first and then to remain nearly constant until the materials are almost consumed. The quantity of zinc consumed is very nearly that required by theory, showing that there is almost no local action and that it is therefore not necessary to raise the zinc out of the liquid when not in use. It is therefore well adapted for lighting on a small scale, for telegraphy, electrolysis, etc. The formation of the solution of zinc does not appear to lower its resistance, while the reduction of the oxide of copper to metallic copper diminishes the internal resistance. In using them for lighting or purposes requiring much energy, they are used at, or near, the point of maximum output, which is when the external and internal resistances are about equal. But under these conditions the useful potential is also reduced to about a half, that is, to .4 to .5 volt per cell. Thus, for incandescent lighting it is necessary to have about twice as many cells as the pressure in volts at the lamps. A battery of the large trough cells is said to run two lamps in derivation, presumably 12 to 15 volt lamps. A precaution is necessary in running lamps; as the initial E. M. F. is about double the normal, it is necessary to switch a resistance in series with the lamps at the moment of starting, in order to save the lamps from the strain of the high initial E. M. F. at starting. For charging accumulators, 4 cells must be used for one accumulator. For medical purposes it may be used for a surgical lamp or cautery. On account of its great current capacity it is especially well adapted for signal work or similar purposes, in which strong momentary currents are required.

As there is no local action consuming the zinc when not in use, it is very well adapted for open circuit work, especially when the intermittent current required is comparatively great. It is largely used for microphones and has been adopted by the Société Générale des Téléphones at their central stations. Notwithstanding the low E. M. F., one cell is said to be able to replace a Leclanché, probably owing to its low resistance and the fact that it does not polarize. The latter property adapts it very well for telephonic transmission of operatic, theatrical and musical entertainments, requiring long, uninterrupted service. In such service one of these cells is replacing 5 Leclanchés.

The cell gives off no odors, forms no creeping salts as in the Leclanché, requires no adding of water, or other attention. The solution of zinc formed is very soluble and no crystals attach themselves to the zinc, which therefore requires no cleaning or scraping. The attention and cleaning required by the ordinary Daniell cells used in the large telegraph central stations is by no means a small matter; in London, for instance, there are 27,000 Daniell cells, requiring three miles of shelving.

Regeneration.—After the oxide of copper has been reduced by the action of the cell it can be rendered active again by exposing it to the air for several weeks or by roasting it at a red heat on an iron plate. The cell can also be regenerated by passing a current through it in the opposite direction.

Capacity.—For the same weight the cell is said to have five times the capacity in ampere hours, as compared to accumulators. But such a comparison is misleading, as current cannot be used without potential, and as the useful difference of potential is between one-half and one-quarter that of an accumulator, a true practical comparison should include both, in other words, should be a comparison of energy and not of ampere hours. For the same weight, the useful energy may perhaps be 1½ or even 2 times as great.

Precautions and Objections.—The principal precautions to be taken are that the liquid does not come into free contact with the air, as that changes it into carbonate, and care must be taken not to get the liquid on the hands or clothes. The former is overcome by hermetically sealing the cells, or covering the liquid with a layer of oil. The latter objection is overcome by supplying the salt in an iron box from which it is poured directly into the cell, and water poured over it, so that no handling of the liquid is required. Another objection was that the zinc was rapidly eaten off just at the surface of the liquid. This has been overcome by fastening the zinc on an amalgamated brass rod or strip, so that the zinc is wholly immersed; there appears to be no local action if the brass is well amalgamated.

The prices are from $1 for the small one to $4 for the large trough cell. The zinc, oxide of copper, and the potash for a recharge cost, each, about $1.

These cells have been adopted by the Société Générale des Téléphones, by the Administration des Postes et des Télégraphes, and are used among others in the London Post and Telegraph department.

Tests.—The following extracts are taken from various reports: M. E. Hospitalier discharged the small form illustrated above, through .8 ohm, obtaining about half an ampere for six days' continuous running, or 259,000 coulombs (about 70 ampere hours). The theoretical capacity of the 88 grains of zinc consumed is 260,000 coulombs, showing an almost entire absence of local action. For full report see *l'Electricien*, Aug. 1, 1883. Dr. d'Arsonval obtained 25 amperes from this one, and 106 from the large one, on short circuit. He found that by increasing the temperature from 20° C. (67° F.) to 50° C. (122° F.) the current increased from 4 to 12 amperes regularly with the temperature, and as the E. M. F. remained the same it was due to diminution of the internal resistance. He also finds that there is no local action. See *La Lumière Electrique*, Aug. 25, 1883. In the *Electrician* (London) Jan. 25, 1884, Sir William Thomson gives some results which he obtained. In *La Nature*, Dec. 1, 1883, M. Hospitalier gives some results of running a small light.

CELLS OF LECLANCHÉ TYPE.

The chief exhibit of cells of this class was that of LECLANCHÉ & CIE. (French Section. Gold medal), the original makers of the famous Leclanché cells.

Original Cells.—These cells were usually made of a porous cup containing a plate of carbon and filled with broken fragments of carbon and peroxide of manganese (the mineral pyrolusite of commerce); the negative pole is a zinc rod, and the liquid is chloride of ammonia, the sal-ammoniac of commerce. The zinc is amalgamated and the solution should be a saturated one.

Modification.—The improvement made some time ago, and already well known, and fast replacing the porous cup pattern, was to make hard, conglomerate blocks of the peroxide of manganese with the carbon, which blocks are held to the carbon plate by rubber bands; this replaced the porous cup and its loose contents. The resistance and polarization are thereby diminished, and consequently the useful difference of potential and current is increased. These conglomerate masses are made of broken pieces of retort carbon, peroxide of manganese and shellac, under hydraulic pressure.

Recent Improvements.--The more recent improvements exhibited were the following: The conglomerate mass is made in the form of a hollow cylinder having a metallic terminal fastened to the top, as seen in the accompanying illustration, Fig. 4. The zinc rod, having a tinned wire terminal at the top, and a small rubber cap at the bottom, is placed in the inside of this cylinder and is held concentrically by the cap shown. This increases the depolarizing power of the peroxide of manganese, it being a more rational disposition of that material; the resistance is diminished still more, and the distribution of the current and consumption of the zinc is more symmetrical; the volume and weight are also diminished by this construction; the unreliable rubber bands are dispensed with. This construction enables the price to be diminished 25 per cent. The constants of this cell are, E. M. F., 1.5 volt; internal resistance (a few days after being set up), .4 ohm; weight of positive pole, 1¼ lbs.; price of cell complete, 73 cts.

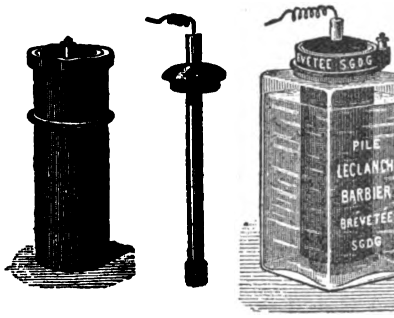

FIG. 4.

New Salt.—Another one of their novelties is a new salt, to be used in place of the sal-ammoniac. The latter has the very objectionable feature that crystals deposit on the zinc, which thereby becomes insulated and is rendered inactive, and which causes the zinc rod to be eaten through, or "cut off" at the top of the liquid, long before it is consumed below. The positive pole also becomes clogged with these crystals. The new salt, which is said to be a mixture of 75 per cent. of ammonium chloride and 25 per cent. of chloride of zinc, obviates the formation of these adhesive crystals and thereby keeps the zinc perfectly clean, enabling it to be consumed evenly and completely. It sells for 26 cts. a pound.

Dry Cell.—Another of their improvements for which they claim a great future is their so-called "dry cell," a poorly chosen name, as the action of all such cells depends on their property of keeping *moist;* a better name would be humid, or moist cells. It consists of a cylindrical vessel of zinc which forms the retaining cell and the negative pole; in this is a conglomerate cylinder similar to the one described above. Between the two is a mass of plaster of paris, moistened with a solution of their new salt; the top is closed with wax. It is sold ready for use. It has the great advantage of requiring no setting up or cleaning and is particularly applicable in cases where the cells are jolted about, as on trains, boats, etc. Its capacity appears to be almost the same as that of the usual cells; see Fig. 5. It sells for 87 cts.

The diagram, Fig. 5, gives a series of discharges made of different cells, showing some of their qualities. The discharges were continuous, through an external resistance of 10 ohms.

After 30 days' continuous discharge, the dry cell still gave 50 milliamperes; the discharge of the ordinary porous cup cell fell to this current in about 15 days. The replaceable conglomerate blocks are of such a size that they are consumed in the same time that one zinc is consumed.

Minor Improvements.—Some of the minor improvements are as follows: In the porous cup cells the porous cups have slits cut into them to increase their porosity. A "cavalry battery" to be used on horseback in military service is made of small carbon plates having a zinc plate cemented to it on one side with a paste of boiled oil and plumbago, making an electrical and mechanical contact; these are piled one over the other with sheets of blotting paper between them; the whole is strapped together without any retaining cell. To render it active, the whole is dipped into the solution, long enough to merely wet the blotters. All the cells are evidently connected in series by this construction.

Instructions.—The instructions regarding their cells are, that the zinc should be amalgamated, the solution completely saturated, that new solution should be added when the old becomes milky, that the addition of chloride of zinc solution is advantageous, and that tinned wire is preferable for connecting the cells.

Other Exhibits of Leclanché Cells.—Among the minor improvements of the Leclanché type of cells as exhibited by different exhibitors are the following: HENRI SERRIN (French section. Honorable mention) exhibited retaining cells made of a single block of wood, lined on the inside with a waterproof coating. Two or more holes may be made in the same block, making a battery of cells complete in itself. He claims cheapness, strength and lightness, and, being sealed, there can be no creeping of the salts, and the cells are as convenient as the "dry cells." He claims that the blocks cost only 0.8 cent each, to make. A complete battery of two cells in one block sells for 39 cents. He furthermore makes his contact to the carbon with a tinned zinc strip, so as to avoid the oxidation of the usual brass terminal.

J. WARNON (French section. Bronze medal) exhibited a new form of terminal to the carbon plate. He claims that in the usual construction, local electrolytic action forms a salt between the metal terminal and the carbon, destroying the contact. In his terminal the brass binding post is tipped on its inside end with platinum, which is pressed against the carbon, by being the end of a screw which passes through the cast lead cap of the carbon. He replaces the porous cup by a coarse linen canvas bag soaked in turpentine and resin, enclosing the active material and tied around the carbon. He claims for this, cheapness and rapidity of discharge. For instance, a half gallon cell with 4 carbons and selling for $1.16, gave 40 amperes on short circuit. He claims that he can regenerate the peroxide of manganese of old cells, so that it can be used over again. This is probably done by charging the cells in reverse direction. He also exhibits some small portable medical cells, 1x1x2¼ inches, selling for only 19.3 cts. each.

THE WESTERN ELECTRIC CO. (United States section. Gold medal for collective exhibit) exhibited Leclanché cells with the porous cups replaced by cotton bags; also porous cups with slots, and canvas around them; also porous cups with holes near the top to replace the usual glass tubes through the top; also glazed cells with numerous holes and a canvas bag on the inside, to replace the porous cup.

CH. R. GOODWIN (French section) makes a large cylinder of the conglomerate mass, having secured to it a zinc rod, forming together one piece. This, he claims, will give 2 to 2¼ amperes on short circuit.

MESSRS. RENAULT & DESVERNAY (French section. Honorable mention) show a "dry cell" in which the moist mass is a siliceous gelatine.

OTHER BATTERIES FOR SMALL CURRENTS.

Among other cells for small currents not of the Leclanché type are the following:

CHAS. CHARDIN (French section. Silver medal), one of the principal makers of electro-medical apparatus, exhibited some very conveniently arranged medical cells which he claims are almost half the weight for the same capacity, and which do not require the cleaning and attention of other cells; an important item for a physician. While the first cost is greater, the cost of maintenance is more than correspondingly cheaper. The cells consist of a high, narrow, cylindrical retaining cell, having a carbon and a zinc rod fastened on the cover which is common to all the cells of a battery. The liquid is bisulphate of mercury, filling about one-third of the cell; on this floats a large cork which fits the retaining cell loosely. In the state of repose the electrodes are separated from the liquid by this floating cork, which also serves to almost seal the cell so as to prevent slopping. By depressing the electrodes this cork is forced down, and in doing so forces the liquid up to electrodes, thus putting the battery into action. As it is necessary to raise the electrodes out of the liquid when not in use, the box containing all these cells is so arranged that the lid cannot be closed until the electrodes have been raised, which is done by a counterweight or spring. The top of the box

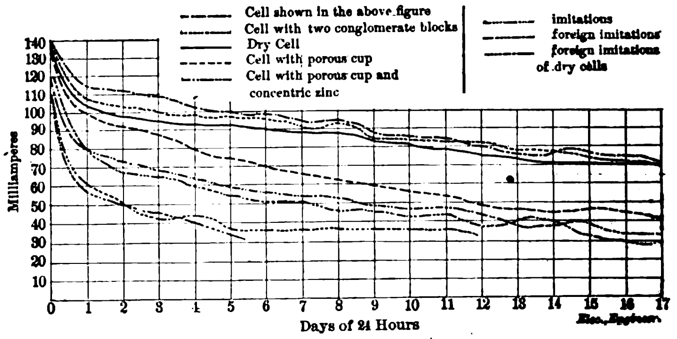

FIG. 5

contains all the ordinary accessory apparatus used for medical purposes. The E. M. F. is 1.526 volt.

The cell of **Dr. Fontaine-Atgier**, exhibited by **Mors** (French section), was also intended for medical purposes. The electrodes are zinc and copper, the latter having a mixture of peroxide of manganese and coke secured around it by means of a sack of thick, ordinary pasteboard. The liquid is potassium hydrate (the soapmaker's potash of commerce); the E. M. F. is 1.49 volt. The advantages claimed are that it can be used on open circuit work; it is quite constant and the resistance is low. A battery of a large number of cells is constructed without retaining cells, as follows: All the electrodes as above described are fastened in pairs connected in series, on a common lid, the zincs being tied against the pasteboard. To put it into action the whole is dipped for a moment into a large tank containing the liquid, and is then withdrawn. Enough liquid rests in the pasteboard to actuate the battery. The whole is arranged to be convenient for transportation.

M. L. **Maiche** (French section. Bronze medal) exhibited a battery in which the depolarization is effected by the air. The negative electrode consists of scraps of zinc in a bath of mercury; the positive is made of a receptacle in the upper part of the jar containing fragments of crushed coke which have been coated with a very thin layer of platinum black; this coke rests half in and half out of the liquid, allowing the air to be absorbed by the platinum black. It is claimed that one of these cells has been in action more than 10 years without any attention. He also exhibited a salt to be used in place of sal-ammoniac which he says will dissolve eight times the quantity of zinc as compared with sal-ammoniac.

Chemically Pure Zinc.—It is in place here to mention the exhibit of **Louis Cahaigne** (French section. Bronze medal), who exhibited chemically pure zinc produced by a new process by means of which it can be made cheaply. It is well known that local action in the zinc used in batteries is caused by the impurities in the zinc; if therefore the zinc is free from other metals it will not be attacked on open circuit, and will not need to be amalgamated, which is a source of trouble and entails no small expense. The process of this exhibitor enables him to make chemically pure zinc at a sufficiently low price to enable it to be employed in batteries. It can be made for 1 franc per kilogramme, or 8.8 cts. per pound, which is very low. Numerous reports from chemical experts are given, showing this metal to be really chemically pure.

Another process of obtaining pure zinc was exhibited by M. L. **Letrange**, but as this is an electrolytic process its description is given under that heading.

Miscellaneous.—**Messrs. Perreur-Lloyd & Fils**, exhibited a battery in which the *residue* of the action was sulphate of copper. But as the electricity generated was a mere by-product, the object being to manufacture sulphate of copper, the description is given under the heading of galvanoplastics.

Mr. Thomas A. Edison exhibited a "chalk" battery, but as the action is probably thermic, it is described under that heading.

References.—For other generators of electricity, see respective headings. For battery carbons, see "Carbons." For substitution of dynamos for batteries on telegraph lines, see "Telegraphy."

EXTENSIVE ELECTRIC RAILWAY PROJECTS FOR WHEELING, W. VA.

In addition to the millions of dollars now being invested in Wheeling, W. Va., by the Eastern capitalists interested in the construction of the great railroad enterprises embraced in the plans of the Wheeling Bridge and Terminal Railway Company, Pittsburg and local capitalists have formulated enterprises for the development of the city and its practical consolidation with the thriving manufacturing towns on the Ohio bank of the river which will call for the expenditure of about $1,000,000. The ideas of these people embrace the construction of three highway bridges across the Ohio, the building of a large electric power and lighting plant, and the construction of about eight miles of electric railroad, extending to the Ohio towns the ten miles of electric railway now in operation in the city.

Two corporations, working jointly, and composed for the most part of the same stockholders, are engaged in the prosecution of this work. One is the Wheeling Bridge Company, with a capital of $500,000, and the other the Bridgeport Bridge Company, with a capital of $300,000. The first-named company has already contracted for two bridges at a cost of $552,000, and work is in active progress upon them. The first will connect the main portion of the city with Wheeling Island, and the second the island with the towns of Martin's Ferry and Ætnaville on the Ohio side.

A double-track electric railroad will run over the bridges and will afford rapid and easy communication with the city. The Bridgeport Bridge Company will erect a bridge from the island to the mainland on the Ohio side, giving like facilities to the people of Kirkwood and Bridgeport. An electric railway line will also cross this bridge and will extend five miles into Belmont County, Ohio, along the old National Road, through a dense population. This bridge, the electric road, power house, etc., will cost about $350,000.

In addition there is projected an electric road from the suburban town of Benwood, the present southern terminus of the existing electric road, twelve miles south to Moundsville, the county seat of Marshall County, and stock is being rapidly subscribed in the East.

The Wheeling and Elm Grove Suburban Road has been extended to Elm Grove, five miles, and laid with sixty-pound rails. The effect of these improvements will be to consolidate a population of nearly 100,000.

PROGRESS IN ELECTRIC WELDING.

In process of construction at the gun factory in Watervliet is a 10-inch gun which, when completed, will be one of the greatest calibre and most wonderful in its design ever made in this country. The huge gun will be built according to Captain Crozier's latest design of wirewinding. Captain Crozier is located in the ordinance department at Washington, and the present gun is the fourth of its kind in existence. The work of boring the gun has been completed, and Thursday next it will be placed in the lathe preparatory to commencing the wire winding. The square wire to be used will be of steel, as is also the gun proper, a tenth of an inch in thickness and will be wound from the breech to the muzzle, the entire length. To produce the desired work a dynamo has been placed in the gun factory which will be utilized to weld the ends of the wire by electricity.

The great demand for artificial ice machines, and the necessity for furnishing long coils of pipe to be used in their construction, has furnished a new and extensive field for the pipe welding machines of the Thomson Electric Welding Company. The difficulty of welding pipe by the old methods is that, unless the joints are perfect, there is an escape of ammonia vapor which renders them practically useless. It is found that by the electric welding process these joints are perfect, and lengths of 400 or 500 feet of homogeneous pipe can be made without difficulty. The electric welds stand bending either hot or cold, and by this process it also becomes practicable to frequently test the coils as they are being bent, and so correct any defects as the process of pipe bending goes on. It is also found that by the electric welding machines the pipe can be brought to any degree of heat that is necessary, and special bends made without the introduction of U joints or couplings, as heretofore has been the practice. Long lengths of pipe, with joints which can be relied upon, can thus be laid in the streets of the various cities for conveying cold from the refrigeration apparatus to consumers. Great demands are being made upon the company from various quarters for apparatus for these purposes. The works of the welding company, at Lynn, are crowded to the utmost to supply machines on orders received.

Roebling's Sons & Co., of Trenton, N. J., have made contracts with the welding company for seven additional machines, to be run from a central dynamo for welding copper wire. This is in addition to the plant which they already had in constant operation day and night since December, 1888. Contracts have been made with the United States Government for a complete welding plant for boiler tubes, bars, rods, etc., for the New York Navy Yard, and also a similar plant to be applied to ship construction at the Norfolk Yard. Several plants are in successful operation in carriage and wagon works in the West, and other plants for the purpose will soon be installed. There are many new developments of the electric welding process which will soon be made public. The welding machine for shell shrapnel and other projectiles is now completed, and arrangements will soon be made by the company for producing these in large quantities.

PHOTOGRAPHING UNDERGROUND.

The use of electricity enabled a photograph to be taken recently under most exceptional and difficult conditions. A landslide occurred at a quarry in France, and a large number of workmen were buried in the subterranean gallery. It was supposed that the men were entombed in one of the galleries about 220 feet below the mouth of the mine; but nothing certain was known of their position, and for an attempt at rescue to have any chance of success an approximate idea of their whereabouts had to be gained. The difficulty was surmounted by sinking a shaft about a foot in diameter, in the direction of the gallery, and through it lowering, by means of a chain, a small camera, mounted in a metallic tube. The camera was pivoted within the tube at its upper end, so that it might be fixed at any angle by tightening or slackening the connecting cord. Above and below the camera were placed rows of incandescent lamps, and when the apparatus had been lowered, the camera was made to incline outward from the case. In order to photograph the interior of the gallery all that was necessary was to turn on the current and light the incandescent lamps, the plate being exposed at the same time. In this manner excellent results were obtained from a photographic point of view, the time of exposure being five minutes.

MEETING OF THE ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.

The Ninth Annual meeting of this Association was held at Niagara Falls, N. Y., on June 18 and 19. The following members were present:

C. A. Darlton, president, Washington, D. C.; P. W. Drew, secretary, Chicago, Ill.; C. W. Hammond, St. Louis, Mo.; C. Selden, Baltimore, Md.; A. R. Swift, Chicago, Ill.; G. L. Lang, Boston, Mass.; G. C. Kinsman, Decatur, Ill.; G. T. Williams, Cleveland, O.; M. B. Leonard, Richmond, Va.; R. Stewart, Elizabeth, N. J.; A. Ramseur, Atlanta, Ga.; I. T. Dyer, St. Joseph, Mo.; U. J. Fry, Milwaukee, Wis.; H. C. Reed, Milwaukee, Wis.; J. B. Stewart, Weehawken, N. J.; M. Magiff, St. Albans, Vt.; W. J. Holmes, New York, N. Y.; W. W. Nichols, Chicago, Ill.; W. F. Taylor, Altoona, Pa.; O. C. Greene, St. Paul, Minn.; W. E. Lewis, Long Island City, N. Y.; H. C. Sprague, Kansas City, Mo.; G. M. Dugan, Jackson, Tenn.; L. B. Foley, New York, N. Y.; C. S. Jones, Chicago, Ill.; A. R. Singafelt, Topeka, Kan.; E. A. Smith, Boston, Mass.; S. K. Bullard, Sedalia, Mo.; T. W. Stacey, Marshall, Tex. Many ladies were also present.

The first session of the meeting was called to order by President Darlton, on Wednesday, at 10 A. M. After the reading of the annual report, the following new members were elected:

J. C. Ford, St. Paul, Minn.; W. J. Stonebromer, Two Harbors, Minn.; H. D. Milton, Texarkana, Tex.; J. V. Goode, Kansas City, Mo.; P. H. Hough, La Crosse, Wis.; G. N. Gish, Marshallton, Ia.; H. B. Briggs, Redwing, Minn.; T. W. Parks, Tyler, Tex.; J. N. Miller, Dallas, Tex.; W. D. Hendrickson, Long Branch, N. J.; B. R. Pollock (the world's champion sender), Hartford, Ct.; and L. Horton, Jr., St. Paul, Minn.

The following officers were elected for the ensuing year:

George T. Williams, of Cleveland, O., president; George M. Dugan, Jackson, Tenn., vice-president; P. W. Drew, of Chicago, Ill., secretary and treasurer, was re-elected. M. B. Leonard, Charles Tilden and G. C. Kinsman were appointed a committee on time and place of next meeting.

As the attractions of Niagara are available only by daylight, it was decided to devote the afternoon to a tour along the American and Canadian shores of the Falls and rapids, and substitute an evening session for that usually held in the afternoon.

The first paper of the evening, of which the following is an abstract, was read by Robt. Stewart, Supt. of the Central Railroad of New Jersey, on the "History and Development of the Block System." Mr. Stewart was the first railroad telegraph superintendent to introduce this system of signalling in America. He was at the time connected with the Camden and Amboy Railroad, over which nearly all the Eastern troops passed during the war. A rear collision, which occurred at Bristol, Pa., in the summer of 1863, causing the death of a large number of soldiers and the fireman of the engine, led to the investigation of an English block system, at the request of Ashbel Welch, then president of the company, and Mr. Stewart was instructed to experiment with and put in use a signal, by which trains could be notified, without being stopped on the track, that the next point was clear. After some experimenting, he placed in operation seven block stations upon the 25 miles of road, between Trenton and Kensington, using the banner signal, in conjunction with the regular telegraph offices. There were two fixed glasses, the upper two white, and the lower red, with two independent lamps, one for east and one for west bound trains, which were operated by hand, with a rope attachment. This arrangement proved defective, and a single lamp, with a movable red flannel shield, was substituted. A record of the trains was kept on a board with pegs. The telegraph operators used the regular Morse system for notifying adjacent stations that trains were in or out of the block.

The experiment proved so successful, that it was extended from Trenton to New Brunswick, covering 26 additional miles of road in 1864. Shortly after, upon the formation by consolidation by the United Railroads of New Jersey, the system was extended to Jersey City, making it complete from Philadelphia to Jersey City, excepting between the cities of Newark and Jersey City. In 1870 a connecting road from Frankford Junction to Mantua was equipped, making a total distance of 90 miles. From the establishment of this system up to the date when the road was leased by the Pennsylvania R. R., no rear collisions of any kind occurred, which he attributed to the fact that only the "positive" block was used, in contradistinction to the "permissive" block, afterwards introduced by the Pennsylvania R. R., by which two trains were permitted upon a block at the same time, by observing caution.

In 1873 the Pennsylvania R. R., began the introduction of the system to a limited extent on the Pittsburg division of the main line. Its extension was very slow until the winter of 1875–6, when it was rapidly extended over the entire main line. Its use was stimulated by the approaching centennial exhibition, and in spite of the enormous increase of traffic, the protection was so complete that no accident occurred which could be attributed to its failure.

As originally introduced, the blocks were of considerable length, depending upon local conditions; but on the main line the distance varied from six to ten miles. The signal now used is the standard semaphore. The Pennsylvania R. R., has now a continuous block system from Jersey City to Pittsburg, and from Philadelphia to Washington, the most extensive in this country, and also on the Northern Central division. The officers pronounce it a great success, and an absolute necessity to the road.

On the Central R. R. of New Jersey the electric pneumatic block signal system of the Union Switch and Signal Company, was put into operation in April, 1890, between Jersey City and the Newark Bay draw, a distance of eight miles. The blocks ranging from 1,000 to 1,800 feet are operated on four tracks. At the commencement of each block, signal posts are erected, one for each track, carrying two semaphores. When the upper semaphore is at right angles, it indicates that a train is on the next block. When it projects in this way, the lower one is also set at "danger" or "caution." As the train leaves the block thus protected, the upper signal falls, but the lower remains at caution until the next block is passed and the train is two blocks distant.

These semaphores are operated by pneumatic pressure, controlled by electricity. Those on one block are insulated from the preceding and following blocks. At the end of the block first touched by a train, the right and left hand rails are connected by a wire placed in circuit with two cells of gravity battery. At the other end of the block the same rails are connected through an ordinary relay. When no train is on the block a current passes through this rail circuit holding the armature of the relay in contact, forming a circuit for the local battery. When a train enters upon the track its wheels and axles short circuit the battery, releasing the armature of the relay and breaking the local circuit, having a battery of 8 cells. The local battery operating the semaphore magnet, when its circuit is closed forces open a valve which admits compressed air into the semaphore cylinder and the piston is driven down, forcing the samaphore into the "safety' position. With the entry of a train upon a block, the relay being thrown out of action, the local circuit is opened and the semaphore is drawn by a weight into the "danger" position. Where the "home" and "distant" signals are both operated under these conditions, the arrangement of circuits is more complicated. The supply of compressed air is furnished by a plant of compressors communicating by pipes with a series of reservoirs placed along the line at the foot of the signal poles, and pipes are connected from there to the semaphore signals. The ordinary ties are found to afford sufficient insulation for the rails, but the fish-plate joints not being of ample conductivity are re-inforced by iron wire connections. Between the blocks the rail ends are insulated.

Mr. Stewart then described the various systems of block signals which had been actually introduced, beginning with the Hall system, which was first used on the Eastern railroads in 1871, and has since been greatly improved. Other systems referred to were the Sykes, used on the New York, New Haven and Hartford Railroad, and the Black mechanical signal, the latter being used on the elevated railroads in New York and Brooklyn. Another form of automatic signals used in this country is known as the Union Switch and Signal Co.'s Block System, which has been introduced on the Boston and Albany, Old Colony, New York, Providence and Boston, and a number of other roads. In 1882 it was adopted on the New York and New England Railroad.

The Chicago, Milwaukee and St. Paul Railway Co. has a block system in operation on 146 miles of their Chicago and Council Bluffs division, using a double arm semaphore placed in a position to be seen from both directions. It is operated by hand in connection with an ordinary Morse telegraph.

The Cable Electrical Signal is being experimented with on the Staten Island Rapid Transit Road.

The Chesapeake and Ohio Railroad use a system similar to that of the Pennsylvania Railroad, covering all tunnels and trains going down both sides of the Allegheny mountains, using the Hudson semaphore signal.

The Chicago, Burlington & Quincy Railroad have practically three different systems in use, all non-automatic, the difference being mainly in the manner of connection between offices. The main line from Chicago to Pacific Junction, 482 miles, is now operated under what may be called the "permissive" block. The New York Central Railroad has begun the introduction of a pneumatic-electric system on that part of its track between Woodlawn Junction and the Harlem River, the same as that used on the Central Railroad of New Jersey. The New York Central is also equipping fifteen miles of track near Poughkeepsie with the Hall system. The New York, Lake Erie and Western Railroad uses a block system on 232 miles. Other railroads using various block systems, are the Boston and Maine; Philadelphia, Wilmington and Baltimore; the Missouri Pacific; the Canadian Pacific and the Lake Shore Railroads.

A signaling system operating a visible and audible signal in the cab has recently been introduced by the Desart Electric Co., of Columbus, Ohio. It is used on the suburban road north of the Harlem River. Another electric block system is owned by the Pennsylvania Steel Co.

In closing his explanatory paper, Mr. Stewart said that the system of blocking trains has been, and could be, improved, and that the time is not far distant when upon all the main trunk lines of the country the business will have grown to such an extent that in order to move all trains at a higher rate of speed, especially freights, it will be necessary to locate signal towers at such distances as will permit the use of the "absolute" block to govern all their movements. Speed and safety were so closely allied in the successful operation of railroads that whatever tends to their accomplishment the progress of the times would not permit to be ignored. If a simple and inexpensive automatic system could be devised for operation between the main block stations, a long step in advance would be taken. "Permissive" signaling might then be used with absolute safety at the main stations, as the auxiliary would act as an "absolute" intermediate block.

Mr. Charles Selden read a paper upon the increased adhesion between the wheels of a locomotive and the track, caused by the passage of electricity based upon the experiments and patents of Elias E. Ries, of which the following is an abstract:

From competent authorities on motive power, it has been determined that a locomotive, having a weight of 100,000 pounds, has a tractive power upon the rail, when in best condition, of but 25,000 pounds. And when the rail, by reason of the weather, is in a bad condition, the tractive power amounts to only about what an engine of 15,000 pounds weight should have. In other words, on good rail, by non-adhesion, the locomotive gives but twenty-five per cent., and, on bad rail, but eighteen per cent. of the power which, theoretically, should be had from it.

Efforts were made some fifteen years ago by an Englishman named Werderman, to overcome the non-adhesion, by winding the spokes of the driving wheels with wire, thus making a magnet of the wheel, with the view of attracting the wheel to the rail by magnetism, thus increasing the friction, and, thereby, the adhesion to the rail on the part of the locomotive. Having but a primary battery, it is plainly to be seen that the results were so slight as not to be appreciable. Another objection, even had the dynamo been used, was that, in order to secure sufficient magnetism to be of benefit upon such an immense machine as a locomotive, the magnets would have to be very large, and the winding upon the spokes of the drivers would have necessitated a change in the construction of the engine, so that as the bobbin was being revolved by the wheels there would be room to clear the firebox on the inside and the side-rods of the locomotive on the outside. This, of course, would render necessary a longer crank pin for the bars, and, being longer, it must necessarily be stouter in order to stand the increased leverage, so that a device of this character for the locomotive engine would not be economical, and would necessitate the reconstruction of all locomotives using it. This inventor filed patents in this country and several others followed in his foot-steps, but nothing practical has yet been evolved from that method.

Recently Mr. Elias E. Ries, an American inventor, secured letters patent upon his method of increasing the adhesion of the locomotive to the rail, by the use of electricity, and he took a wide departure from the path pursued by former inventors. Mr. Ries proceeded upon the hypothesis, that an electric current of large volume, if properly employed, could be used to weld metals. Acting upon this theory, he proposes to arrange upon a locomotive, a dynamo of sufficient power, to be run by a small auxilliary engine, and to pass the current from the dynamo to the driving wheel of the engine, along the rail to the next driving wheel, through its axle and the other wheel to the other rail and back to the first driver, thence to the dynamo; thus making a local circuit, so to speak, which would travel with the locomotive, passing a current through the drivers and along the rail as indicated; and for this purpose, by a very simple method, he insulates one pair of the driving wheels. By this means the inventor proposes to cause an incipient weld between the driving wheels and the rails. I say incipient because the wheels, being in motion, the weld, if any, is being made and broken by the revolution of the wheels; therefore, a perfect weld is not obtained; nor, of course, would it be desirable except for brake purposes, as in descending a grade for instance.

If the theory advanced by Mr. Ries can be made a success, practically, it means a great many things to the railroad world. If, by means of this invention, the tractive power of a locomotive is increased, say even twenty-five per cent., it means ten additional cars on a forty-car train. It means a large gain in the hauling capacity on high grade railroads; it means increased speed for passenger trains; it means a saving, indirectly, of fuel; it means the employment of lighter locomotives to do the same amount of work as the heavier ones, thus being easier on the road-bed and bridges, and the mounting of grades that would not be considered possible at the present time. All this, provided, that in practice, on a locomotive, the theories advanced shall hold good.

Another feature of this invention is that it is not necessary to keep the current flowing all the time unless you need it, but when you stop the train and want to start it, your locomotive at that time not being in motion, a more perfect weld is obtained, thus enabling you to start at once without slipping, and after you have gotten your train under headway, your current, if desired, may be switched off; so much for the pulling power and so much for the motor.

The statements made by Mr. Selden were questioned by Mr. Nichols, and a model motor and track were introduced to prove the assertions claimed by the inventor. The experiments made were entirely satisfactory and convincing to the most skeptical—the only question being as to the practicability and economy of the application on a large scale.

Mr. W. F. Taylor followed with a paper on "Lighting at Wrecks." After referring to the importance of powerful artificial lights to facilitate the clearing away of wrecks at night, Mr. Taylor gave a description of the electric light car used upon the Pennsylvania Railroad.

The car itself was an ordinary box car, having an end door with a small extended platform and windows, A 15 h. p. boiler is at one end, surrounded with water tanks of 800 gals. capacity. Near this is a coal box holding two days' supply of fuel. At the opposite end of the car is a 15 h. p. Westinghouse engine, making 300 revolutions per minute. Near the centre of the car is a 10-light Weston dynamo making 1,000 revolutions per minute. Suitable receptacles are provided for tools, lamps, etc. On one side of the car two reels of wire are permanently fastened, one of which contains a wire that is run out as a feed wire, the other being connected to the last lamp of the circuit and is used as a return wire. The lead wires are connected with a brush which connects with the axles of these reels, thus giving a path for the current. Upon the top of the car are carried tripods and tools for hanging the lamps. The car is manned by a crew of one engineer and four linemen. In starting for a wreck the regular crew is always preferred, as they are thoroughly drilled. Arriving upon the ground the first thing is to locate the car; then determine the number and location of the lamps. Then a man is started out with the end of the wire from the small reel, followed by another carrying pole, spike and hammer, or tripod, as required; then the third man with the lamps and a short section of wire; continuing till the last lamp is reached, when the wire on the larger reel is run out and connected with the last lamp, thus completing the circuit. The lamps are swung from the most available points, portable poles being used if necessary. These are usually made of 4″ x 4″ hickory, 18 feet long with the lamp. At the bottom a piece of 1″ gas pipe is clamped to the pole. To erect the pole a steel bar is driven into the ground, and the pole is then lifted up so that the gas pipe will go over the steel bar. In the bracket at the top of the pole is a pulley through which a rope passes and thus draws up the lamps. The pole is more easily handled than a tripod.

The time occupied in starting up the lights is shown in the following instances: Wreck No. 1, 7 lamps, ⅜ mile of wire, started in 1 hour; No. 3, 7 lamps, ¼ mile wire, 1¼ hours; No. 4, 6 lamps, ½ mile wire, 35 minutes. The cost of equipping a car ready for service was about $2,500. In operation it costs about $1 per lamp per hour, but even if it cost $5 per hour it would be worth it.

Mr. Taylor gave descriptions also of the Lucigen and the Wells lamp, both of which used petroleum. The Wells light is now being used by the Pennsylvania Railroad, and both styles were in use after the Johnstown flood.

Papers were read by Mr. M. B. Leonard, on "Electric Lighting in Railway Service;" by Geo. C. Kinsman, on "Train Despatching, Its Uses and Abuses;" by Prof. H. S. Pritchett, of Washington University, St. Louis, on "Correct Time, How Shall We Maintain It?" The meeting adjourned Thursday evening to meet next year at Cincinnati.

There was a larger number of exhibits than usual, among them being that of the Hall Signal Company, the Edison Phonoplex System, the Edison-Lalande Battery, the Electric Secret Service Company, the Pennsylvania Steel Company, the Molecular Telephone Company, P. B. Delany, the O'Neill Crossing Signal, and the Desart Electric Company, W. T. Brown, president and general manager, and the Brown Electric Protective Company, of Philadelphia, Pa.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

MAGNETISM AND FLUORESCENCE.

[130.] If any of your readers have made or have heard of any investigations as to the action of a powerful magnet on phosphorescence or fluorescence, I will consider it a great favor if they will publish the facts, or communicate with me, in your care.

BOSTON.

Trial Trip of the Tripp Manufacturing Company's New Eight-Wheel Car.—Legislative Investigation of Methods of Securing Elevated Railway Franchises.—Thomson-Houston Dividend.

By invitation of the Tripp Manufacturing Company, a number of gentlemen representing the Tripp Company, the Thomson-Houston Company, the West End Street Railway Company, and other electric railways, were present at the trial trip of their new car on the lines of the West End Company. The car started from the Grove Hall stables at 7.30 P. M., and reached the Tremont House at 8 o'clock, whence it made a trip to Allston and back. The car has already been described in these columns, but a repetition may not be inappropriate at this time. The car, which was built by the Newburyport Car Manufacturing Company, is mounted on double trucks and has eight wheels. It is 28 feet long from door to door, 7 feet, 3 inches wide, 7 feet, 9 inches in height from floor, and has seating capacity for 46 passengers. Each truck has four steel wheels and one 15 h. p. Thomson-Houston motor. The car is provided with vacuum and hand brakes, and the brakes are operated by a toggle joint arrangement, giving immense power. The Tripp anti-friction bearings are used throughout, and the car is hung on trucks of an entirely new design (on which patents are pending), the equalizing bar being connected to the journal boxes underneath, instead of passing around the top as hitherto. The car is also provided with the Jewett frictionless car centres, which carry the weight of the car on frictionless rollers that move with the slightest strain, permitting the car to adjust itself to the movement of the trucks. There are less parts and fewer bolts about the new Tripp truck than on any other form of truck, and they leave plenty of room for the application of the motors and electrical apparatus. The trip was entirely satisfactory, except in rounding some of the sharper curves, where considerable difficulty was experienced owing to the trolley wheel coming off the trolley wire; but a few changes which are contemplated will undoubtedly overcome this difficulty.

The official investigation into the alleged irregularities in the methods of several of the elevated railroad companies to obtain a franchise in the city of Boston, has been thoroughly pushed this week and is still in operation. No decision has, however, as yet been arrived at, and the flood of testimony goes to show that no actual corruption of members of the legislature exists, though large entertainment is fully and freely admitted by the West End and other companies.

The Thomson-Houston Co. has declared a semi-annual dividend of 3½ per cent. on the preferred stock, payable July 1. On the same day dividends will be paid on series C and D securities in amount not yet determined, but contingent upon negotiations for the sale of securities liable to culminate before the payment falls due.

Boston, June 21, 1890.

BALTIMORE.

City Electric Lighting.—New Deals and New Companies.

The all absorbing topic in Baltimore just now is how and by whom the city electric lighting is to be done. The situation is rendered more interesting by the purchase of the Waterhouse and Brush Electric Companies by the Westinghouse Electric Company —this combination being one factor in the fight—and the acquisition by the Fort Wayne Electric Co., of Mr. J. Frank Morrison, so long and well known in electric lighting circles through his connection with the Brush Electric Company, of Baltimore, and his management of the Baxter Electric Motor and Mfg. Co., lately re-organized under a slightly different corporate name.

The Fort Wayne Company has certainly secured an effective champion in Mr. Morrison, as the exciting incidents of the past few weeks have shown. After a brisk struggle, the Baltimore Common Council passed an ordinance, giving the Brush Company authority to light the city of Baltimore for a period of five years at 40 cents per light. At this juncture, Mr. Morrison has succeeded in impressing the mind of the Mayor with the idea that it would be an injustice to the city of Baltimore to bind itself for so long a period at this price when the Fort Wayne Company in the course of four months stand ready thoroughly to equip a plant capable of doing the same work and at 30 cents per light. The Mayor's impression would not be of such vital importance were it not for the fact that incidentally it carries with it a refusal of his signature; so the end is not yet.

The Brush Company contend that their investment should be protected, that the company who risked its all in the establishment of Baltimore's first electric light industry, when electric lighting was in its infancy, should have the co-operation of the city, especially after the faithful performance of its contracts for so many years; while the new company say that the name of Mr. Morrison is sufficient guarantee that they are in earnest, that the city should not shoulder an unnecessary expense, when only a few months will develop an opportunity for retrenchment. At a meeting of the Council Committee before whom the whole matter was discussed a few days ago, some of Mr. Morrison's friends good-naturedly twitted him of playing the part of "Ajax defying the lightning." This was because he appeared single-handed in joint debate before this Committee, with the officers and board of directors of the Brush Company, the company whose manager he had been until recently. In view of the unanimous passage of the ordinance in favor of the Brush Company and against Mr. Morrison and the Fort Wayne interests, it seemed as though the simile was well drawn; but now that the Mayor sturdily refuses to sign the ordinance under any circumstances, it begins to look as though the "Ajax" might come out ahead of the lightning after all. It is claimed by those who are familiar with the situation that if the Brush Company had long ago taken Mr. Morrison's advice and consolidated with the Waterhouse interests, Mr. Morrison would still be at the helm and there would have been no split. However, it remained for the Westinghouse Company to show the shrewdness to make the consolidation by purchasing these companies outright, and at this juncture Mr. Morrison severs his connection with the Brush interests and champions the new cause. The situation is being watched with great interest and the denouement will end for a time one of the most exciting political and corporate contests that Baltimore has seen for many a day. Probably the contest never will be really ended, as in such a political cauldron as is Baltimore, it will always be impossible for any effervescing reaction to precipitate the salt of indifference.

Baltimore, Md., June 21, 1890.

PITTSBURG.

Motors in Mining Work.—New Works of the Standard Underground Cable Co.—The Allegheny City Plant.

The Hercules Mining Machine is rapidly coming into general use in the coal district of the Monongahela Valley. Owing to the fact that the miners are getting scarce here, coal operators hail with great satisfaction this new electric mining machine. At the Summerhill mines, near Woodville station, five of the machines have now been in use for several months, and they have been a thorough success there from the very start. The Hercules Mining Machine is operated by the Tesla alternate current motor of the Westinghouse Electric Company. The motor and the system have given such good satisfaction that Messrs. Armstrong & Co., the owners of these mines, are now putting an alternate current electric light plant in the mines. Since the introduction of the Hercules mining machines in the Summerhill mines, each machine has produced on the average for every working day, 48 tons of coal, and if the fact is taken into consideration that it only requires one man to operate the machine, an idea may be had of the great saving. Several of the machines are now being put in the mines of the Monongahela Gas Coal Company.

A manufacturing plant for the production of iron electric light poles has been established here under the name of the Whitmore Mfg. Co. The firm finds the field a comparatively new one and reports a large number of orders ahead.

Another of the Westinghouse industries is about to remove its manufacturing plant from this city into the country. This time it is the Standard Underground Cable Company, for which a large tract of land has been secured at Brinton, on the P. R R., about 12 miles from Pittsburg, and a mile from Wilmerding, the new home of the Westinghouse Air Brake Works. There will be six buildings comprising the entire cable plant, two of them with dimensions of 60 by 276 feet and the remainder 60 by 80 feet. All the buildings will be of brick and stone. A town is also being laid out near the works for the accommodation of the employes. This town will have the peculiarity of having all its streets named by electrical expressions, for instance, there will be Electric avenue, Volt street, Dynamo way, and so on.

On the first of July the Allegheny City electric light plant will commence operations. The power house is now completed and all the wiring of the lines, the putting up of the towers and mast arms has been finished. The plant has a capacity of 3,000 incandescent lamps and 450 arc lights. The Westinghouse alternate current system of incandescent and arc light apparatus are to be used here. The power house is probably one of the most comprehensive structures for its purpose in this country. It is only two stories high and the entire machinery is placed on the ground floor, which affords an easy observation of the entire plant. At the very rear of the building is the boiler room with 6 Erie boilers and a Roney stoker each. The latter is an economic appliance for the use of coal. The engine capacity is composed of seven 100 h. p. compound engines, one 50 h. p. and four 15 h. p. engines of the Westinghouse standard type. These engines are belted to the three 1,000 incandescent dynamos, two exciters and nine 50-light arc machines. The lights are distributed throughout the town by 52 towers and 25 mast arms. The Allegheny people are congratulating themselves upon the prospect of the new light and there is no doubt that the city will be one of the best lighted in the country.

Pittsburg, June 21, 1890.

LITERATURE.

Electric Light Installations and the Management of Accumulators. By Sir DAVID SALOMONS, Bart. London, WHITTAKER & Co.; New York, D. VAN NOSTRAND Co., 1890. 334 pp. Price, $1.50. Second notice.

THIS volume, considerably revised and enlarged, is a fifth edition of the well-known little work on accumulators first published about four years ago. Each edition as it has appeared has been partially rewritten and amplified until the present volume has entirely outgrown the scope of the original work, which consisted mainly of a description of the interesting installation at the author's residence at Broomhill. Already French and German translations of the earlier editions have been published which, with the appearance of a fifth edition so soon, indicates an extensive circulation, partially attributable, no doubt, to the monopoly of the subject matter which the book has so far enjoyed.

The author himself remarks with surprise that up to the present time no other book has been written on the special subject of the management of accumulators, and suggests a very remarkable explanation of the cause. According to Sir David there are only two classes of persons who are interested in the subject, viz., the manufacturers and the users; and as the former cannot be expected to know very much about batteries, their knowledge being confined to laboratory tests, and few of the latter having either the necessary experience or time to write on the subject, the requisite qualifications are only possessed by the few scientific observers who may happen to become users. Very likely some of the men who have devoted their energies to improving accumulators, and who have borne the brunt of introducing them into commercial service, will be inclined to take exception to this very peculiar reasoning.

It is rather remarkable, nevertheless, in view of the many articles that have appeared from time to time in the electrical journals, and the numerous papers read before electrical societies on the subject of accumulators, that no comprehensive treatise embracing the theory, applications and management of accumulators has yet appeared. The works of Reynier and Tamine, published respectively in 1884 and 1885, describe various practical forms of secondary batteries which had been introduced up to that time; the little work of Gladstone and Tribe contains an excellent account of the chemistry of secondary batteries, while the articles and papers referred to have touched upon almost every application of such batteries to the arts; yet, notwithstanding the abundance of material, such a compilation is yet to be forthcoming.

The author of the present volume has not made use of much of the rich matter at hand, but has preferred in the main to confine himself to the records of his personal experience and observations, which, however, have not been inconsiderable. This experience has been gained during several years past in equipping and operating an accumulator plant for lighting the author's private residence. Upwards of $40,000 has been expended in the construction of this installation, of which a considerable part has been sunk in experiments. The work is divided into two main divisions, the first treating of the forms and actions of accumulators, and the second being descriptive of working installations. While the first part is so written as to give the reader a very clear idea of the peculiar nature and actions of a secondary battery and the conditions under which such a battery should be set up and operated, the second portion of the book, on the other hand, is rather too limited and vague in its descriptions of circuit connections, making it somewhat difficult for anyone not previously acquainted with the devices to obtain what may be called "working" knowledge of the systems described.

The several chapters comprising the first division of the volume are devoted respectively to a general description of cells, setting up of cells, charging, discharging and probable causes of failures and their remedies. The batteries described are those manufactured by the Electrical Power Storage Company, and those of the Elwell Parker types, both of which embody the essential features of most commercial accumulators. The construction of these cells, and the general principles governing their actions, with rules for their management during charge and discharge are explained in a simple and practical manner, and much useful information relating to the setting up and manipulation of an accumulator battery is embodied.

The first chapter of the second division indicates the main requirements and some of the more essential minor details for gas, oil and steam engines suitable for driving dynamos for moderate sized lighting plants, and describes many of the more recent improvements which have been made in such engines. Among these may be mentioned a novel boiler feeder and a new automatic drip cock for attachment to engine cylinders. Several forms of English dynamos and motors are illustrated, and the operation and handling of the same explained in a very practical manner. Much information regarding the erection of shafting and the care of machinery generally is also included. In the following chapter various switches and indicating instruments employed in accumulator installations are illustrated and described, as well as various forms of incandescent lamps and fittings and methods of wiring. The prevention of fire risks forms the subject matter of the next chapter in which the rules and regulations issued by the Society of Telegraph Engineers and Electricians are printed in full.

Methods of automatically governing the operation of combination plants, and the actions of secondary cells when worked in conjunction with dynamos are discussed at some length in Chapters IV and V. The behavior of the cells during charge and discharge is explained very clearly, but the great number, and the expensive character of the instruments employed to effect automatic regulation, and the complexity of the system as a whole, give a very erroneous idea of the simpler requirements of an ordinary plant. The author's main potential regulator which is the essential feature of the automatic system described, is, unfortunately, not illustrated, and the description of this instrument is so vague that those unfamiliar with its general design will be likely to obtain an imperfect idea of its character. Although foreign to the scope of the book, the general principles of the alternating current system are next explained, and after brief chapters on testing and estimates, the work is brought to a close by a brief account of the installations at the author's town and country residences.

The book is illustrated by nearly 100 engravings, but it is to be regretted that it does not contain more diagrams which go so far towards explaining clearly the methods of working accumulator installations. On the whole the volume contains a great deal of useful information, and we hope the author may in a subsequent edition find room to cover the whole field of the subject in the manner hinted at above.

REPORTS OF COMPANIES.

MR. VILLARD'S NORTH AMERICAN COMPANY.

The following important circular has been issued to the stockholders of the Oregon & Transcontinental Co. by Mr. Henry Villard, president. It will be seen that the new "North American Company" is to pay its attention to electric light and power :—

The Board of Directors have much pleasure in informing you that they have succeeded in making provision for the payment of the outstanding bonds of the Company. The Northern Pacific Railroad Company having agreed to place at our disposal a sufficient amount of its consolidated 5 per cent. bonds for that purpose, a contract has been entered into with a strong syndicate under which the payment of the bonds under the terms of the mortgage on November 1, 1890, is assured. The syndicate includes Messrs. Drexel, Morgan & Co., J. S. Morgan & Co., of London, Drexel & Co., Speyer & Co., Brown Bros. & Co., Kuhn, Loeb & Co., L. von Hoffman & Co., J. & W. Seligman & Co., Winslow, Lanier & Co., Edward Sweet & Co., Lee, Higginson & Co., John D. Rockefeller, the Deutsche Bank, Berlin, Jacob S. H. Stern, Frankfort-on-the-Main, and L. Speyer-Ellissen, Frankfort-on-the-Main.

The main obstacle to the reorganization of the Company having thus been removed, your Board were enabled to determine the definite course of procedure to that end under the authority vested in them at the meetings of the stockholders of June 17, 1889, and November 5, 1889, and now lay before you the reorganization programme decided upon.

It is proposed to form a new corporation, whose charter will more certainly give us the desired powers than the existing one does. After careful consideration of all the questions involved by ourselves and by counsel, it has been decided to reorganize under the laws of the State of New Jersey, and that the name of the new Company shall be The North American Company.

It was first contemplated to reorganize with a smaller capitalization than the present one, but a very large majority of the stockholders objected to a reduction. With the ascertained consent of fully three-quarters of the stockholders, it is intended to make the authorized capital of the new company the same nominal one as that of your company, viz.: $50,000,000, but of which only $40,000,000, corresponding to the outstanding stock of your company, shall now be issued.

The new company will offer to exchange, share for share, four hundred thousand full-paid shares of its stock of the par of one hundred dollars each, for the outstanding four hundred thousand shares of your stock.

Thirty days will be allowed for effecting the exchange. Your Board will arrange so that stockholders who do not make the exchange shall have their share of the assets of the Company either in kind or in cash at an appraised value. In order to obtain a valuation, the fairness of which no one shall be able to dispute, the Presidents of three of the leading Trust Companies of New York city will be invited to make it. Should a partial sale or distribution of the assets become necessary, the Company will have to be placed in a state of liquidation, which can be done at any time under the direction of the Board of Directors, as authorized by the stockholders at their meetings.

Due public notice will be given of the successive steps in the reorganization, as explained in the foregoing, by this Company, as well as by the new Company.

We do not hesitate to strongly recommend in advance to all stockholders to come into the new Company, for the following reasons:

(1.) There is every ground to believe that the career of the new Company will be a prosperous one from the outset. There will be among its stockholders individuals and firms in this country and Europe of large influence and resources, and it can rely upon the support of strong financial groups here and abroad.

(2.) It is intended that the company shall operate mainly in two special fields. One is that of railroad financiering. As we are certain of the regular custom of several large and prosperous railroad systems, we can confidently look forward to an extensive and profitable business in this connection. The other field will be the promotion of electric light and power enterprises. The substitution of the electric light for other illuminants, and of electric for steam power in manufacturing and transportation, that is now progressing all over the civilized world, and nowhere more rapidly than in this country, offers the greatest opportunities for the lucrative employment of large capital. It is expected that the company will have the closest affiliation, as a stockholder and otherwise, with the Edison General Electric Company and the Thomson-Houston Electric Company, which two powerful corporations do most of the electric lighting and nearly all the business of equipping electric railroads in the United States. The general public have but a limited understanding of the great growth already attained by the industries devoted to the practical application of electricity and the enormous development of which they are capable. But we feel sure that the use of your capital in this direction will bring large returns.

More detailed information regarding the new company will be submitted in its formal invitation to you to become stockholders in it.

THE STATUS OF THE CONSOLIDATED ELECTRIC STORAGE COMPANY.

THE Consolidated Electric Storage Company, of this city, have just issued the following important circular defining their status and their plans as manufacturers of the Julien battery and the exclusive licensees for the United States of C. F. Brush's storage patents:—

We take this means of informing you that this company has been organized for the manufacture and sale throughout the United States of the Julien Storage Battery. To that end, it has acquired those storage battery patents which, in its opinion, control the manufacture and sale of storage batteries for the United States.

In order that you may understand the scope of those patents, we will describe in a few words what constitutes a storage battery as at present universally made.

Gaston Planté, whose storage battery was the first to attract public attention, used the following method. He employed two plates of lead, which he immersed in a solution of sulphuric acid and water; he then applied a current of electricity which had the effect of creating on the surface of the plates, by disintegration of its substance, a spongy substance, known as *active matter* or *absorptive material*, being spongy reduced metallic lead on one plate and peroxide of lead on the opposite plate. This process required several weeks and sometimes months of charging, involving too much labor and expense to make the Planté battery one of commercial value. Radical and fundamental improvements were needed to make the storage battery what it is to-day. To Charles F. Brush, of Cleveland, Ohio, has been awarded, both by the United States Patent Office and the United States Circuit Court,[1] priority of invention of those improvements. Mr. Brush obtained the same technical results as Mr. Planté by applying the active matter to the plates *mechanically* before immersing them in the solution. He also made *receptacles* in the plates and *mechanically* filled those receptacles with lead oxides (active matter) by *pressure*. He then put the plates into the solution and subjected them to a charging current, by means of which he obtained in a few hours the results which Planté reached only in weeks or months of charging. The battery thus made had, moreover, much greater capacity than those of the Planté type. This method has, for obvious reasons, superseded that of Planté, and since Mr. Brush's invention (1879) all commercial storage batteries are made by applying the active matter mechanically to the plates. The plate, wall or support to which the oxides are applied is known as the *support plate* or *conducting support*, and the oxides applied to the conducting support are generally called the *active matter* or *absorptive substance*. The solution in which the conducting support, with the absorptive substance applied thereto, is immersed, and which usually consists of sulphuric acid and water, is called the *conducting liquid* or *electrolyte*. Mr. Brush applied for patents for his inventions. He was put in interference with Camille A. Faure, who made similar claims to invention,[2] and after a long and bitter contest for a period of four years before the patent commissioners, Mr. Brush was awarded priority; and on March 2, 1886, United States Patent No. 337,299 was issued to him. This patent covers broadly the *mechanical application* in any form (whether powder or paste) of the *active matter* or *absorptive substance* to a support plate. This is the decision of the United States Circuit Court in the case referred to. Any method of application by hand or machine is "mechanical." The court also decides that the words "active matter" and "absorptive substance," as used by Mr. Brush, are synonymous, and include not only lead oxides but every other substance that is absorptive (and it must be absorptive to be of any value), applied to a conducting support." It does not matter what shape or size the conducting support may take, whether it be smooth, perforated, woven wire, flat, cylindrical, etc.; so long as it is a "conducting support," it is an infringement of the above patent.

In addition to this broad invention, this patent also covers, expressly and by specific claims, the support coated with mechanically-applied metallic oxide, oxide of lead or equivalent lead compound, and red lead; and also such a support when provided with "receptacles" filled with the mechanically-applied oxide of lead or other "active material."

The word "receptacles" was found by the Court to include perforations extending through the plate.[3]

This patent has nearly thirteen years still to run and is controlled by this company. Another important patent now controlled by this company was sustained by the United States Circuit Court, viz.: Patent No. 266,090, covering a support with "cells," "cavities," "slots" or "perforations," and the words "cells or cavities" were held by the Court to include perforations as well as cavities of other forms.[4]

Patent No. 260,654, also controlled by this company, covers the application of the "absorptive substance" to the "conducting support" by "*pressure*," whether exerted by hand or a machine.

The batteries made by the Gibson Company, The Electrical Accumulator Company, The Pumpelly Company, The Woodworth Company, The McLaughlin Company, The Anglo-American Company, and others, consist, all of them, of a "conducting support" and "absorptive substance" mechanically applied thereto, and are clear infringements of the Brush patents.

This company has also acquired United States Patent of Edmond Julien, No. 347,300, covering an "inoxidizable" "conducting support." Experience has shown that the "conducting support" is so influenced by the electric current as at an early stage to oxidize and become disintegrated. Mr. Julien, who was one of the first inventors and workers in the field of the storage battery, has discovered a certain alloy of lead and other metals, whereby this defect in the plain lead support is overcome. It is regarded as a most valuable invention. The patent has ten years to run.

To guard against imposition by persons who may pretend to have discovered a new battery, we wish to inform the reader that it is universally admitted that so far as scientific research has gone, only the metals and their salts (metallic oxides), may be employed to make a commercially useful storage battery, and only those metals and their salts may be employed which are practically insoluble in the electrolyte. The elements or electrodes of a commercially useful storage battery consist of two parts, first, a "support," and second, an "active" or "absorptive" substance applied and secured to the support. Gold and platinum, but for their costliness, would be the most useful metals to employ for the support, as they are practically inoxidizable in the electrolyte, or exciting fluid or solution of the battery. Of all the cheaper or base metals, lead possesses in the highest degree this immunity from attack by the exciting fluid or solution, and for this reason it has been chiefly employed where a simple metal has been used for the support plate.

The alloy of lead, antimony and mercury patented to Edmond Julien is, however, far superior to lead in this respect, and approaches more nearly than any other metal or alloy, the cost of which would permit its use, to gold and platinum.

Many attempts have been made to use various metallic compounds for the active or absorptive substance to be applied to the supports. These have been applied in various ways, but no commercial success has yet been reached by any experimenter in the use of any substance or by employing any method of application except reduced (or spongy) metallic lead and its oxides, mechanically-applied and secured to the support plate.

Time would be wasted in listening to the pretensions of any inventor who professes to have contrived a commercially useful storage battery the elements of which do not consist of a metallic support practically inoxidizable in the electrolyte or solution, having mechanically applied to or secured thereon either reduced spongy metallic lead or one of the oxides of lead, or equivalent lead compound.

This company has also acquired United States Patents No. 383,757 and 408,986, of Henry G. Morris and Pedro G. Salom. Messrs. Morris & Salom have been engaged, for some years past, in devising suitable machinery for the effective and economical manufacture of storage batteries. These patents cover a machine known as the Mechanical Filler. Prior to the invention of this machine, the active matter was applied to the "conducting support" by hand. The method was laborious and expensive and the work generally uneven and unsatisfactory. The mechanical filler obviates all these difficulties. By its use each machine dispenses with the labor of from thirty to forty men, and fills the plates uniformly and far more effectually than can be done by hand. It is the first and only machine of the kind that has ever, so far as we can learn, been invented or claimed to have been invented, and as it is both novel and highly useful, we deem the validity of the patents unquestioned. These patents have about sixteen years to run. It will be seen from the above that agents and electric companies, in recommending the batteries of this company to their customers, will be freed from the annoyance of litigation.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The following gentlemen were elected to associate membership in the Institute, by the Council, on June 17:—

Cleveland F. Dunderdale, agent Westinghouse Electric Company, 146 Adams street, Chicago, Ill.

Eugene R. Holcomb, electrician, agency Thomson-Houston Electric Company, 234 Montgomery street, San Francisco, Cal.

H. A. Sinclair, electrical engineer, The Tucker Electric Company, 950 Bedford avenue, Brooklyn, N. Y.

F. H. Chamberlain, electrician, Metropolitan Railroad Company, 2411 P street, N. W., Washington, D. C.

George Cutter, dealer in electrical supplies, 192 Fifth avenue, Chicago, Ill.

John S. Cobb, with S. R. Krom, general manager and mining engineer, 151 Cedar street, New York.

J. P. B. Fiske, electrical engineer, Thomson-Houston Electric Company, Lynn, Mass.

H. G. Reist, electrical engineer, Thomson-Houston Electric Company, 113 Franklin street, Lynn, Mass.

James B. Cahoon, electrical engineer, Thomson-Houston Electric Company, 257 Washington street, Lynn, Mass.

Axel Ekstrom, electrician, Thomson-Houston Electric Company, Lynn, Mass.

R. B. Owens, superintendent, Greenwich Gas and Electric Light Company, Greenwich, Conn.

Geo. L. Colgate, electrical engineer, Bedford Electric Company, Bedford City, Va.

George Francis Myers, laboratory of Wm. Stanley, Jr., U. S. Electric Lighting Company, Newark, N. J.

Augustè F. Mason, general manager, Simplex Electric Company, 620 Atlantic avenue, Boston, Mass.

Harvey L. Lufkin, general agent, "C. & C." Electric Motor Company, 404 Greenwich street, New York.

William H. Powell, New Britain, Conn.

M. J. Francisco, president and general manager, Rutland Electric Light Company, Rutland, Vt.

Messrs. A. J. Lawson, C. H. Davis, M. Brooks, D. C. Jackson, F. E. Jackson, T. Stebbins and Dr. L. Bell were transferred to full membership.

The last meeting of the Institute of the season was held on June 17, when papers on alternating current work were read by Prof. H. J. Ryan and Messrs. Powell and Humphreys, all of Cornell University.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

At a meeting of the Executive Committee, held Monday, June 16th, it was decided, as stated by us last week, to convene the Twelfth Convention of the National Electric Light Association at Cape May, New Jersey, on Tuesday, August 19th. Full details of the arrangements made for the Convention will be published at a later date.

Mr. Allen R. Foote entered upon the duties of Secretary and Treasurer of the Association on Tuesday June 17th.

Mr. J. E. Lockwood, chairman of the committee on papers, has issued a circular inviting papers as well as likely names and topics.

THE ORDER OF RAILWAY TELEGRAPHERS.

The Order of Railway Telegraphers, which is credited with a membership of 8,000, has been holding a convention in this city during the past week, some 70 divisions being represented. It was the fifth annual convention of the order. The order is essentially benevolent, and while it seeks to promote the general welfare of its many members. its constitution declares that a forfeiture of membership shall be incurred by any member who shall instigate a strike.

LEGAL NOTES.

THE THOMSON VAPORIZING METER IN THE PATENT OFFICE.—THOMSON vs. TAVENER.

In the interference proceedings between Prof. Elihu Thomson and Tavener relative to the electric meter in which current is measured through the medium of a liquid vaporized by a heated conductor in circuit, the examiner granted the motion of Prof. Thomson's counsel and held that the British patent did not disclose or illustrate an operative device, for which reason he dissolved the interference. It was strenuously contended by counsel for Tavener, at the hearing before the primary examiner, that the defects of the British patent were immaterial, but the examiner held otherwise.

Prof. George Forbes also claims to be the inventor of the method of measuring electricity consisting in vaporizing a liquid by the heating effects of the current and then measuring the amount of vaporization. This is the subject of his patent No. 387,505, August 7, 1888. This invention is claimed by Prof. Thomson as his own, and an interference is now in progress in the Patent Office between the patent of Forbes and an application of Prof. Thomson. The examiner attempted to place the burden of proof upon Thomson in this interference, but upon appeal, the Commissioner by a recent decision shifted the burden of proof from Thomson and placed it upon Forbes, Thomson having been the first to file an application in the Patent Office showing and describing the invention. The counsel for Prof. Forbes have recently made a motion for re-hearing, which will be heard by the Commissioner shortly.

THE SHALLENBERGER METER.—THOMSON vs. SHALLENBERGER.

The Shallenberger patent of November 5, 1889, No. 414,595, for the Shallenberger meter, has been placed by the Patent Office in interference with an application of Prof. Thomson, which was pending in the Patent Office at the same time with the application of Shallenberger. The parties will shortly begin to take their testimony.

PLATINUM.

The demand of the electrical industry for platinum is making that already precious metal more precious. The price, it is announced, has already risen 100 per cent. in value within the last year, and it is expected to continue in its upward course, never, perhaps, to be cheaper. It would be a small fortune to the chemist who could provide a substitute.

INVENTORS' RECORD.

Patents issued June 17, 1890.

Alarms and Signals:—*Combined Fire-Alarm and Gas-Lighting Device*, C. H. Crockett and C. C. Allen, 430,175. *Burglar-Alarm*. S. Broichgans 430,378.

Conductors, Conduits and Insulators:—*Insulator*, S. Oakman, 430,296. *Underground Electric Cable*, W. R. Patterson, 430,297.

Distribution:—*Method of Synchronizing Alternate-Current Machines*, E. W. Rice, Jr., 430,320.

Dynamos and Motors:—*Regulator for Dynamo-Electric Machines*, E. Thomson, 430,327. *Alternate Current Motor*, E. Thomson, 430,328.

Galvanic Battery:—*Voltaic Battery*, T. A. Edison, 430,279.

Lamps and Appurtenances:—*Manufacture of Incandescent Lamps*, W. L. Voelker, 430,156. *Arc Lamp*, A. C. Alcock and H. Galopin, 430,260. *Electro-Magnetic Cut-Out for Electric Lamps*, E. Thomson and E. W. Rice, Jr., 430,326. *Electric-Arc Lamp*, E. Thomson, 430,357. *Incandescent Lamp*, F. C. Rockwell, 430,437 and 430,485.

Measurement:—*Electric Meter*, J. Oulton and J. Edmondson, 430,432. *Electric Meter*, G. H. Wade, 430,551.

Metallurgical:—*Magnetic Separator*, T. A. Edison, 430,275 and 430,280. *Process of Melting or Reducing Metals by Electricity*, T. J. Willson, 430,453.

Telephones and Apparatus:—*Telephone*, J. H. Irwin, 430,128. *Phonogram Blank*, T. A. Edison, 430,274. *Phonograph*, T. A. Edison, 430,276 and 430,278. *Automatic Determining Device for Phonographs*. T. A. Edison, 430,277. *Coin-Controlled Telephone Guard*, S. M. Dowst and F. H. Hosmer, 430,569. *Phonogram Blank*, T. A. Edison, 430,570.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

SOME NEW WESTINGHOUSE INSTALLATIONS.

A few days ago the Westinghouse Electric Company received cable advice from England that it had been awarded the contract for furnishing a complete outfit of its alternate current apparatus for the establishment of a plant in Barnsley, Yorkshire. At a recent meeting of the town councils, that body decided to discontinue the use of gas as an illuminant of the town and substitute the modern method of lighting. The plant is to have a capacity of six thousand 16 c. p. incandescent lamps and one hundred arc lights of the new Westinghouse alternating current arc lighting system. The contract is said to have been obtained in the face of the keenest competition.

The Hamilton Electric Light Company of Hamilton, O., has contracted for a 500 light Westinghouse alternating current incandescent dynamo to its plant.

The electric light company at Newport, R. I., which has heretofore been operating the Edison direct current system of incandescent lighting has closed a contract with the Westinghouse Electric Company for one of its 500 light alternating current dynamos.

The electric light has evidently found favor in Washington state. A company which started in the town of Tacoma less than a year ago, with a 750 light plant, has already been obliged to make arrangements for an increase of its capacity. A contract was awarded the Westinghouse Electric Company for alternating current apparatus of 1500 lights capacity.

The Westinghouse Electric Company has received the contract for the installation of an alternating current dynamo of 750 lights in Saginaw, Mich., where an electric light company was recently organized.

Vinton, Ia., is one of the latest central station plants to be furnished with the Westinghouse alternate current apparatus. This plant will start with a capacity of five hundred 16 c. p. lights.

Hiawatha, Kan., is to have an electric light plant of 500 lights. The Westinghouse system of alternate current incandescent lighting will be operated in the plant.

The Cincinnati Zoological Gardens, a public resort, which has justly became famous the world over, not only on account of the magnificent gardens and the romantic scenery, but also for the valuable collection of animals it contains, is about to be illuminated by electricity. The Westinghouse Electric Company received the contract a few days ago to instal one of its 40 light dynamos of the Westinghouse alternating arc light system within the Zoo.

THE CONSOLIDATED ELECTRIC STORAGE COMPANY.

The important circular issued by this company from its offices, 120 Broadway, is printed elsewhere in this issue. To the New York headquarters all communications as to agencies and licenses should be addressed. All orders and inquiries for batteries should be addressed to the company, 926 Drexel Building, Philadelphia. The Atlantic Trust Co., trustee, representing more than two-thirds of the stock of the Julien Electric Traction Co., offers to the remaining outstanding minority stockholders of the said company the privilege of exchanging their stock, share for share, for Consolidated stock, without payment of assessment or expense. The Consolidated Company has a capital stock of $3,000,000 in shares of $25. It has no bonds and no preferred stock, and as is well known, controls the Brush fundamental storage patents.

MORE ELECTRIC CARS FOR RICHMOND.

The city of Richmond, Va., will always be remembered by street railway men as being a place where the superiority of electricity over other methods as a means for propelling street cars was first demonstrated. Although the apparatus installed at Richmond for street railway work was almost the first which had been designed for operating a street railway of any considerable size, the results, as our readers well know, were such as to call forth the admiration of street railway and electrical engineers, and were the direct precurser of the great impetus in electrical equipment which has since followed.

Experience has taught a great many things, and there have been a large number of changes made in the design of electrical apparatus, but it is interesting to note that Richmond is still enthusiastic over electric traction, and that the two other important roads in the city of Richmond, the Richmond City Railway and the Richmond & Manchester Railway have decided to supplant animal power by electric power.

These contracts, one with the City Railway Company, being for 10 cars, and the Richmond & Manchester Road, being for 5 cars, were closed by the Sprague Electric Railway and Motor Company during the last month.

Those who remember the newspaper stories and attacks on the early work at Richmond, when nothing seemed too bad to say of the apparatus, will be interested in the following report from Mr. David Mason, of June 11:—"The cars are running smoothly here at present, though they are carrying very heavy loads. On the 29th of May, the day of the unveiling of Lee's Statue we carried, with an average of twelve cars on the main line, fourteen thousand and eight hundred and forty-five people who paid fares, and probably two thousand people who did not pay fares, and that with old No. 5 motors. Summer cars would have from one hundred to one hundred and fifty people on at one time. Several conductors collected sixteen fares on the roof of the cars. Every inch of room on the cars was occupied."

THE BAXTER ELECTRIC MOTOR COMPANY.

The following circular has just been issued by the Baxter Electric Motor Co., of Baltimore, Md., to the users of electric power:—

"We take pleasure in informing you that the Baxter Electric Motor Company has been organized and has purchased the extensive shops, valuable machinery, patents and other valuable rights and franchises of the late Baxter Electric Manufacturing and Motor Co. and is supplied with sufficient capital to fully guarantee to every company or individual desiring motors, that from this date, there will be no delay or difficulty in furnishing machines or duplicate parts. We especially desire to call the attention of our patrons to the complete equipment of motors for elevator (passenger and freight), street railway service, mining generators, for complete power plant, always proving themselves economical, durable and reliable, as well as up to the rated power. The superior qualities of the Baxter motor have gained for it a standard reputation in electrical and mechanical efficiency which is beyond all competitors The services of a competent and first-class corps of experts have been obtained, and no expense will be spared to win the patronage of those using or contemplating the use of electrical power. The mechanical devices used in the construction of these motors have lessened the cost of manufacture, and we are thus enabled to defy competition. We invite inquiry and will take pleasure in quoting on our regular line of goods; particularly on special construction."

ISOLATINE.

The well known firm of Roessler & Hasslacher Chemical Co., 73 Pine street, this city, are introducing on this market a new insulating material of remarkable qualities invented by the prominent German chemist, Dr. Kunheim. They say of it: "Dr. Kunheim's Isolatine is the most effective electric insulating material known. It is a bituminous viscous liquid mass unexcelled for the coating of wires and cables, for filling in tubes and boxes wherein electrical conductors are placed, for preparing insulating layers, and, in short, for all purposes of protection to electrical conductors against the escape of electricity. The merits of Isolatine are its withstanding all aerial and subterraneous influences (moisture, changes of temperature, sewer and coal gases and acids) as also its unchangeable toughness. It does not grow brittle or porous but retains its elastic gum-like consistency under all conditions."

The Isolatine comes packed in barrels of about 500 lbs.

THE ELECTRICAL SUPPLY CO., CHICAGO.

This enterprising and successful company has recently secured the services of Mr. Charles Wirt, who has resigned his position as Chief Inspector to the United Edison Manufacturing Co., and has already moved to Chicago to assume his new duties. Mr. Terry has done well to associate so able and conscientious an electrical engineer and worker with him, and the new departure will enhance the reputation of the company for good, solid and progressive work.

SCHIEREN BELTS IN THE UTICA ELECTRIC RAILWAY PLANT.

Chas. A. Schieren & Co. of 45-51 Ferry street, this city, say:—"We have just received a report in regard to the five double 'Electric Perforated' belts which we furnished the Utica Belt Line Railroad Co. at Utica, N. Y., viz., that they are the best belts in the opinion of the superintendent that he ever saw, and we think we can conscientiously claim superiority for our 'Perforated Electric' belts over any unperforated belt for this electric power especially. The 'Perforated' belts will run with less tension than an unperforated belt; they can be run very slack and because of this fact they are well adapted to the uneven strain of an electric railway. Electric power is different from electric light, in respect to the fact that it is uneven, sometimes the full force will be on, and at other times thrown off suddenly, and because of the fact that the belts run slack they will adapt themselves to this uneven change more readily than if belt were kept at a tight tension all the time."

GALLANT WORK OF AN EDDY MOTOR.

An interesting episode in which an Eddy motor played the title role, is thus described by the *Toronto Empire* of May 29 :—

Some consternation was caused in the works of the Barber & Ellis Manufacturing Company, on Bay street, yesterday morning, by the breakdown of the engine. As the break was rather serious it was thought that the fifty or so hands which the firm employ would have to remain idle for three or four days until repairs were made. Luckily, however, an "Eddy" electric motor stationed on the third flat, which has done service for a section of the works on night shifts, was brought into use. The experiment of driving all the machinery on the three flats of the building by this motor occurred to the superintendent, Mr. L. P. Bouvier, and its application was attended with the most successful results. Although the motor at 220 volts, develops only five-horse-power, it did the work equally as well as the seventeen horse-power engine with its cumbersome gearing, and the entire staff continued to work the whole day. The current was got from the Toronto Incandescent Electric Light Works on Terauley street. The only stoppage was that of the elevator, it being feared that this would overtax the little "hummer." An idea of the serious loss that would be sustained by the firm if the works had been stopped may be had when it is said that the turn out of envelopes alone is 900,000 per day. A large number of patent machines are used in the manufacture, and they are attended by girls. The machinery driven by the "Eddy" motor on the three flats yesterday included fifteen envelope machines, three cutting presses, eight glueing machines, two box-covering machines, two scorers, three cutters, one embossing press, one corner cutter and five ruling machines. The connections included 800 feet of shafting. Operations in the building yesterday were so satisfactory that it is likely electricity will be adopted as the motive power in the future.

THE COMPLETE ELECTRIC CONSTRUCTION COMPANY.

On June 11, the fine plant of the Manhattan Electric Light Co. in this city was struck by lightning. The switchboard was burnt out, and no fewer than 32 Ft. Wayne dynamos were disabled. Mr. Leslie, the manager, immediately went to work, however, to meet the emergency. He was able, with the help of other local companies, to supply many of his customers, and with the help of the Complete Electric Construction Co., of 24 Cortlandt street, which put a large gang of its handiest men at his disposal, he was able to get all his circuits going last week and to take care again of 20,000 lights. The work thus effected classes with the quickest on record, and Mr. Leslie is entitled to no little credit for the pluck and promptness with which he faced the disaster. The Complete Electric Construction Company now have over 200 men at work.

THE PITTSBURGH REDUCTION COMPANY'S ALUMINUM.

While it is generally understood in a vague sort of a way that aluminum is some day destined to be the all-pervading metal—that on account of its lightness, ductility, malleability, conductivity, etc., it will find its way universally among the arts, it is not generally known that a real live company is turning out the metal at the rate of a ton a week, which out-put is sold weeks and even months in advance.

The Pittsburgh Reduction Company, of 95 Fifth avenue, Pittsburgh, Pa., have recently issued a pamphlet which is not only comprehensive and well conceived, but at the same time really instructive, and which will repay careful perusal. The processes used by this company are those perfected under the patents of Charles M. Hall, by means of which they are capable of offering aluminum in ingots at the very low rate of $2 per pound in lots of one thousand pounds and over ; $2.25 per pound in lots of 500 pounds and over, and $2.50 per pound in lots of 100 pounds and over. Their price list does not stop here, but goes into the details of prices of sheets, rods, wires, and various forms of the metal, besides giving a general dissertation on its properties and a statement of the different uses to which it is particularly adapted. Throughout the catalogue there are interspersed little tables which are exceedingly interesting. For instance, on page 5 we learn that a cubic foot of cast iron weighs 444 pounds, with a tensile strength per square inch of 16,500 pounds ; while a cubic foot of aluminum weighs only 168 pounds, with a tensile strength of 26,800 pounds per square inch. Then follow tables giving the behavior of aluminum after fracture compared with that of other metals, its elasticity, conductivity, etc. On page 12 is an interesting statement to the effect that the Eureka Tempered Copper Co., of North East, Pa., has succeeded in hardening castings of aluminum in the same way as it hardens copper. The most careful and delicate tests have failed to show the slightest hardness given to aluminum by the process of chilling as practised with cast iron. One of the best features of the pamphlet is that aluminum is not made out to be a *perfect* metal—its bad points are indicated as clearly and dwelt upon as strongly as its good ones—all of which imparts an air of refreshing candor, which should be appreciated by the student of commercial literature. The conductivity of aluminum appears to be about three-fifths of that of pure copper wire at a temperature of 57° F., and about one-half of that of copper at the temperature of 170° F. This makes the conductivity of annealed aluminum wire many times that of iron wire, either plain or galvanized. The Pittsburgh Reduction Company is about to expand in order to take care of its increasing orders, and it is not unlikely that a month or two will see its present output of a ton per week doubled and perhaps quadrupled.

THE GREAT WESTERN ELECTRIC SUPPLY CO.

This company are now getting in excellent shape to handle a large supply business, and are ready to receive and execute with the greatest promptitude the largest orders. They have put in a very large and extensive stock of electric and combination fixtures of the handsomest design and workmanship. Mr. Crolius, an expert in this line will have charge of the fixture department. Their handsome suite of offices are now well advanced, and will be ready for occupancy very shortly. The beautiful antique finish which has been employed throughout their construction makes a remarkably attractive appearance. Mr. Chas. G. Armstrong has been appointed manager and electrician of the house goods department, and no more timely and excellent selection could have been made, and he will be a most valuable addition to Mr. Cutter's staff. Mr. Armstrong was for some time superintendent and electrician for G. A. Harmount, who formerly represented the New Haven Clock Co., and is now known in connection with the Monitor Electric Company. All the electrical work in the famous Auditorium building with the exception of the electric lighting plant, was improvised and installed by Mr. Armstrong, who is well known amongst the electrical fraternity as an electrician of the highest ability. He is also the inventor of a new District Telegraph system which will be handled by the Great Western Electric Supply Co., and numerous other important and novel electrical appliances. Mr. C. A. Robinson, formerly of the Sprague Equipment Co., has also placed his valuable services with the company, and is manager of the Electric Street Railway supply department. With such a staff as this under the able leadership of Mr. George Cutter, naught but an immense success awaits the company.

GAS ENGINES IN ELECTRIC LIGHTING.

President Joseph Barstow, of the Atlantic City, (N. J.) Gas Company, is very much elated, says the *American Gas Light Journal*, over the economy that has resulted in the electric lighting department of the company's business as a consequence of the partial displacement of steam power by gas power in the dynamo room. A 50 horse-power Otto engine has been installed in the works on Michigan avenue, and its operation is pretty close to perfection. The company, which has the contract for the public electric lighting of the city, operates the Thomson-Houston system of full arcs and has over 100 lamps in circuit, with the probability that that number will be doubled by July 15th. By the way, the rate charged for arc lighting on public account is very reasonable—25 cents per lamp per night.

"LOCOMOTIVE TELEPHONES."

The idea of portable telephones is by no means new, but a novel application of it is thus recorded in the Washington *Star* of June 7 : "A test was made this afternoon of the electric railway signal of the Universal Electric Railway Signal Company of Richmond, Va. About three miles of the track on the Baltimore and Ohio has been provided with this signal system by way of experiment. The apparatus consists of an electric circuit formed by a single iron rod, which is laid between the tracks, and a wire brush attached to each engine in connection with an electric gong and telephone. Two engines approaching each other on the same track come into circuit at the distance of one mile and a-half or more, according to strength of the battery, and at once the telephone bells ring. This is a signal for the trains to stop, and the engineers may talk with each other on the telephone to discover the trouble, whatever it may be. Two trains were sent out on the Baltimore and Ohio this afternoon with a party, including several gentlemen from Washington and Virginia and correspondents of newspapers in different parts of the country. The tests were made and proved extremely satisfactory."

ELECTRIC MOTORS FOR THE ERIE CANAL BOATS.

An electrical engineer of Buffalo suggests what seems to be a practical plan in reducing very largely the cost of transportation on the Erie Canal. His plan is to adapt the trolley system now generally in use on street railways to the canal. If the overhead trolley system can be applied to street railways at a cost of about half that of horse power, he argues, why can it not be made to take the place of canal mules with a similar reduction in cost? The poles and other appliances for the overhead wires, and in fact the whole plant, covering the entire length of the canal, could be readily arranged without hindrance to navigation. The span would not be too wide at any point. Power stations could be so located as to operate sections of thirty miles on either side, being sixty miles apart, and at some points water power might be utilized.

The great objection to the propeller system would, of course, be the damage to the canal banks through the action of the wheels, but the promoter of this scheme suggests the use of a twin screw wheel or a wheel working low in the water. A motor of smaller size than that used on street cars would certainly accomplish more than six mules now used in caring for two boats, granting that all else was equal. The electricity might be used to light the canal as well as the boats, and a telegraph system could be arranged on the poles used in supporting the trolley wires. One man aboard any of the boats could handle the trolley, and at the same time care for the rudder. The scheme altogether appears practicable. It would also be feasible to use electric motor tugs for the same class of work.

THE EDISON GENERAL ELECTRIC COMPANY.

The Edison General Electric Company has been taking steps for the closer organization of its business and the consolidation of its manufacturing interests. Mr. Samuel Insull has been elected Second Vice-President and entrusted with the direct supervision of the manufacturing and sales departments, and this change has already gone into effect.

PERRET MOTORS FOR MINING WORK.

The Elektron Manufacturing Company of 79–81 Washington street, Brooklyn, have recently experienced a brisk demand for their motors for mining work. Mr. F. A. Perret, their electrician, has just returned from a flying trip West with an order for seven 15 h. p. motors to be used in the mining of coal, in combination with one of the best undercutting machines in the market. Their low speed multipolar type of motor is meeting with great success, as might be expected, the recommendations of such a machine being numerous and often unequaled.

THE WESTERN POWER CONSTRUCTION COMPANY.

The most recent organization, and the only one in Chicago devoting itself entirely to the construction and equipment of steam plants for electric lighting and power work of all kinds is the Western Power Construction Company incorporated by capitalists in Chicago with a paid up cash capital of $500,000. This powerful organization will make its principal business the construction of power plants throughout the entire west, without reference to any special electric system, it having no connection whatsoever with any particular company, but open for business and work of the highest class to all irrespectively. The success of the company is assured from the start and the limit of its operations is still to be found. Mr. Waldo P. Adams has been appointed general manager of the company, a man of immense ability and wide experience in electrical and steam engineering all over the country. The principal offices are located at 144 Adam street in the Rookery. Mr. J. E. Wilson, formerly of J. A. Grant & Co., Boston, is associated with the new concern and will occupy a prominent position therein.

SIMPLEX ELECTRICAL COMPANY'S NON-INDUCTION WIRE.

The Simplex Electrical Company are developing a large field for their non-induction wire for telephone and signal work, and are receiving some good orders since putting up a few months ago the first demonstrative lines. They are also in receipt of some very warm testimonials, and Mr. R. F. Ramsey, treasurer of the Federal Street and Pleasant Valley Passenger Railway Company, Pittsburg, in a recent letter says in relation to its qualities, as follows:—

"It affords us pleasure to say that we have found the anti-induction telephone wire furnished us by your company for our private telephone lines, all and more than was claimed for it. Our system consists of a central station, comprising 14 telephones, and 10½ miles of wire. The wire is placed upon the same iron cross arms, and iron poles, upon which are placed the feed wires from our power station, through which we operate 20 miles of road, and 50 motor cars. We find the service perfect, and disturbance from induction or other cause, entirely absent."

LATTICED IRON POLES.

The Electric Merchandise Co., 11 Adams St., Chicago, are the agents for the "Latticed Iron Poles" manufactured by the Wisconsin Bridge and Iron Co., which are being so largely introduced for street railway work on account of their numerous advantages. The company is in receipt of the following letter from Mr. A. M. Hinckley, Supt. of the Milwaukee Electric Railway Company:—

"To whom it may interest we would say that the latticed iron poles furnished to us by the Wisconsin Bridge and Iron Co. are giving us the very best of satisfaction. We believe them to be the strongest and best pole ever made for this purpose. They are strong and ornamental in appearance and hold the trolley wire up in the very best of shape. We intend to use this kind of pole in all our future construction. We now have over 500 of the poles in use." Such tokens as these speak very highly for the article. We would call the attention of our readers to the announcement in our advertising columns.

TELEPHONES FOR EXPORT.

Mr. James H. Howard, general manager of the Tropical American Telephone Company, sends us a communication calling attention to a new pamphlet entitled "The Telephonic Rights of the Tropical American Telephone Co., Limited," recommending a careful perusal of it. Mr. Howard claims "that neither the Western Electric Co., nor the American Bell Telephone Company ever had any telephonic rights in South or Central America, the West Indies or Mexico but simply in the United States. For convenience sake and to save expenses of experiments, etc., the Tropical American Telephone Co., buys its telephones and transmitters and patented apparatus of the American Bell Telephone Co., *for export to its countries*, and no one else has any right or authority to export them to these countries without permission of the Tropical American Co., and all export orders should be addressed to it direct."

Mr. Howard also states that "The Tropical American Telephone Company has arranged with the well-known Hannover, Germany, house of J. Berliner, brother of Emile Berliner, the inventor, to sell his improved telephonic instruments in Central and South America. Mr. Williams, who has examined the instruments, pronounces them equal to any he ever made for the American Bell Telephone Company in the United States."

TELEPHONES FOR CUBA.

The Compañia Electrica de Cuba of New York, continues to supply telephones for export to Cuba. This company, organized in 1881, purchased in that year from the owners all patent rights in the Island of Cuba, under the Spanish telephone patents of Bell, Blake and others. They furnish telephones—transmitters and receivers—coming direct from the American Bell Telephone Company.

THE CUTTRISS CALCULATING DISC.

This calculating disc is an improved form of slide rule, by means of which a great variety of mathematical calculations can be performed. The instrument consists of a thin metal disc, round the circumference of which slides a ring of corresponding thickness, both the disc and the ring having scales engraved upon them. Two scales are engraved on the disc, and two on the ring, and by placing the scales in definite relative positions with each other, calculations can be readily performed, involving multiplication, division, proportion, vulgar and decimal fractions, powers, roots, and a large variety of problems. With a little practice and by the aid of simple constants many problems specially useful to electrical engineers may be rapidly worked out. The very portable and simple nature of this calculating disc seems to render it eminently suitable for use in outdoor work.

HUNTINGTON SEARCH LIGHTS ON SOUND STEAMERS.

Some weeks ago we illustrated the Huntington search light. The steamer "Connecticut," of the Providence and Stonington Line, has recently been equipped with one of them. Men have been employed on the big boat for the past few months installing the light and getting it in running order. They accomplished their task only a few days ago, and now the big steamer can forge its way through Long Island Sound during nights when fog dims the eyes of the ever watchful pilot without much fear of collision. The wonder is how Long Island steamers ever managed to do without the search light. The search light is situated on top of the pilot house, and is played on any quarter desired by the pilot within. At his will he can throw the powerful light toward the sky or water, and all by the means of a little wheel with a switch. On a very dark night objects at a distance of two miles away can be seen quite plainly. When fog is dense the light is thrown a distance of half a mile. The light, as located on the top of the pilot house, is connected with the regular incandescent system of the boat. By means of a weight that may be operated by a magnet, the steam fog horn of the vessel is brought under the control of the electric current. In the pilot house there are four switches controlling the circuit that runs to the search light and the fog horn, and by means of these switches the pilot can start the search light so that it will flash at regular intervals automatically; or it may be made to burn steadily; or it may be made to flash automatically at the instant the fog horn begins to bellow, and cease to flash when the bellow ceases; or the horn may automatically bellow alternately with the flashing of the light; or the flashing and bellowing may be done alternately or simultaneously by hand. No such use of electricity was ever made before. The "Connecticut's" search light was manufactured by the Scott Electrical Works, and is of 5,000 candle power. The "Rhode Island's" search light is of 4,000 candle power.

THE WENSTROM CONSOLIDATED COMPANY'S NEW FACTORY.

The Wenstrom Consolidated Dynamo Company have bought forty acres of land at Calverton, a suburb of Baltimore, for the erection of their new plant. On this property there is water-power varying from three to five hundred horse-power, the fall being 105 feet. It is the intention to sell as much of this power as will not be needed in their own factory. A considerable amount of it has already been subscribed for at $100 per horse-power year, enough they believe to pay the dividends on the whole power investment. They have also made arrangements to duplicate this hydraulic plant with steam plant so that in case of failure of the water they may be prepared. The building they are now at work on is to be 100 feet wide, and 250 feet long, two stories high, and arranged with galleries for light work. There is a basement of 100 feet square for testing, and a sub-basement of 40x100 for steam boilers, and the four Leffel turbines.

The shop is to be equipped with an electric crane, and will have the most improved machinery throughout. A large number of lathes have been ordered from the Bridgeport Machine Tool Works, also some vertical boring mills. The Betts horizontal boring mills are to be used, Browne & Sharpe milling machines, Newton's special milling machines, and a variety of other tools by various makers. It is the intention to commence work shortly upon the foundry which will have a capacity of five tons per hour.

Work on the new street car motor has already been commenced. The magnetic circuit external to the armature will be in a single casting. The motor is of the four-pole type, with the regular "Wenstrom" armature, the speed being 400 revolutions with an output of 25 horse-power, and the weight 2,000 pounds.

ELECTRICITY FOR MAGNETIC ORE MINES.

A party just in from Mesambria, the newest of the Lake Superior ranges, reports the discovery of a vein of black magnetic ore at a depth of seventy-five feet. The vein is thirty feet wide and has been traced more than a mile. An assay shows 63 per cent. of iron. The mines are located half-way between the Wisconsin Central and the Rhinelander branch of the Lake Shore. The Mesambria range people expect to get a road built down there and begin shipping from half a dozen mines this season. Mines of this class of ore are especially valuable, as the large amount of iron contained in tailings and small pieces of the rock, which has heretofore been cast aside as worthless, can now be economically utilized by means of an electrically operated magnetic separator, which divides these iron particles from the useless substances associated with them.

HEINE BOILERS FOR ELECTRICAL PLANTS.

The Columbus, (Ohio) Electric Railway Company has ordered Heine water tube steel safety boilers for its electrical power station. The Edison Electric Light Company, Chicago, Ill., has ordered 1500 horse-power of Heine water tube steel safety-boilers for its station in that city. The company has been using this type of boiler several years. R. M. Huston, 45 Broadway, New York city, is agent for these boilers.

THOMSON-HOUSTON ROADS IN BOSTON.

The West End Company still continue to increase their electric equipment, and are now engaged in laying new rails on Washington street, south of Elliott street, and on Elliott street. It is their intention to run an electric line of cars from Franklin Park through Shawmut avenue and Elliott street, to Park Square, turning about the Lincoln monument on the return. Current is now being regularly supplied from the Edison station on Head place.

A BIG NEW SWITCHBOARD FOR BOSTON.

The New England Telephone and Telegraph Company has quite outgrown its quarters at No. 50 Pearl street, and welcomes the near completion of the American Bell Telephone Company's new building at the corner of Milk and Oliver streets. The operating room of the New England Company will be on the ninth floor of the new building and will be fitted with new multiple switchboards of the latest pattern, which are now being manufactured by the Western Electric Company, of Chicago, and will accomodate 5,000 subscribers. This new multiple board will cost in the neighborhood of $100,000. The general offices of the company are to be on the eighth floor, giving a grand view of the harbor and the surrounding shores. The wires will all enter the building by underground cable, and will extend to the operating room through a large shaft or well hole. The work of removal will be arduous, but without interruption of the service.

NEW ELECTRIC ROADS FOR ST. LOUIS.

The Missouri Railroad Company, who lately increased their capital stock from $900,000 to $2,400,000, have purchased the Forest Park, Laclede and Fourth Street Railroad. Plans for their power house have been completed. A contract has been closed with Rohan Brothers, of St. Louis, for four boilers 22x60 feet, with eighteen 6 inch flues, to be arranged in two batteries. Contracts have also been closed for two Harris Corliss engines, each 30x60 feet. The countershaft will be 88 feet in length and 8 inches in diameter, fitted with Hill patent clutches. The engines will be geared to the countershaft by means of extra heavy Munson belting and 800 h. p. friction clutches. Floor space will be provided for six Thomson-Houston 75.000 watt generators, five of which will be installed at present. Thirty-six motor cars will be supplied by the Brill Car Company. Motors will be fitted in the cars at the factory before shipment.

The down-town section of the Union Depot Railroad began operation June 1st. Work on the Union Market loop and all other portions of the system is being rapidly pushed to completion. The system will embrace some twenty-two miles of track.

On account of cabling the St. Louis Railroad, the Short electric cars on the south end of that road have been laid up for a month past. The cable work is now nearly finished, and the operation of the Short electric cars will be resumed. Eight motor cars, each fitted with two new Short-Brush motors, are now ready for trial.

The St. Louis Railroad Company are contemplating a plan for operating their Seventh street section and the Cass Avenue and Fair Ground Road—which is controlled by the same syndicate—as a through line. The Short system will probably be adopted.

W. H. GORDON & CO.

The business established not long since under the above firm name by Mr. W. H. Gordon, at 115 Broadway, has already turned the corner of success, and is now handling a large and expansive trade. The company are New York agents for the Simplex wires and cables, and have found a ready appreciation of them not only in the older fields, but in the newer departments of work. Mr. Gordon deals also in a large and well selected line of electrical specialties, and is ready to give immediate quotations upon all classes and quantities of electrical goods.

THE CROSBY DRY BATTERY.

In our advertising columns this week will be found the announcement of the Crosby Electric Company, of the "Judge" Building, Fifth avenue, this city. In that card a number of interesting particulars and technical details are given, and it will be seen that the battery is strongly recommended for certain classes of work. There can be no doubt that for many special uses, the dry battery has very high qualities of advantage, and the Crosby Company proposes to meet the demand.

WHAT THE MOTOR COMPANIES ARE DOING.

In an article in the New York *Sun*, of June 21, on electric power, an idea is given of what the motor companies and their allies, the local lighting companies, are doing in familiarizing the public with the uses of electricity. One part of the article sums up the work of the ubiquitous motor as follows :—"In some cities so far has the use of electric motors gone that it is possible for a man to-day to drink at breakfast coffee ground and eat fruit evaporated by electric power. During the morning he will conduct his business with electrically made pens, and paper ruled by electricity, and make his records in electrically-bound books, his seventh-story office in all probability being reached by an electric motor elevator. At luncheon he will be able to discuss sausages, butter and bread, and at night eat ice cream and drink iced water due to the same electrical energy. He will ride all about the place in electric cars, wear shirts and collars mangled and ironed by electric motor, sport a suit of clothes sewn and a hat blocked by the same means; on holidays ride a merry-go-round propelled by electric motor, or have his toboggan hauled up the slide with equal facility, be called to church by an electrically-tapped bell, sing hymns to the accompaniment of an electrically-blown organ, be buried in a coffin of electric make, and last of all, have his name carved on his tombstone by the same subtle, mysterious, all-pervasive and indefatigable agency. This may sound like a wild and exuberant flight of fancy, but it is simply a faithful statement of the manner in which electricity is being applied to every one of the necessities and luxuries of life in America."

WESTERN TRADE NOTES.

The Ft. Wayne Electric Company are shipping apparatus of 4,000 lights capacity of the Slattery induction system to Duluth, Minn.

Keelyn and Van Denburg have purchased valuable franchises granted in Hyde Park for electric lighting and will immediately commence operations thereunder.

Mr. H. P. Lucas, of the North-Western Electric Construction and Supply Company passed through Chicago this week on his way to St. Paul, returning from an extended and highly successful business trip.

The Elgin Electric Light and Power Company have organized with $100,000 capital and have placed contracts with the Ft. Wayne Electric Co. for an installation of 5,000 Slattery induction system incandescents, and 300 new Wood arc lamps. This plant will be operated with water power.

Mr. Thos. G. Grier, one of the managing electrical and mechanical engineers of the National Engineering Bureau of Chicago, will in future take charge of the electrical department of the editorial work of our esteemed contemporary, *Electrical Industries*. The management of this journal are to be congratulated on their selection, and Mr. Grier may certainly feel satisfied with his connection.

Mr. J. E. Keelyn, of the Ft. Wayne Electric Company's Chicago office, has closed a contract with the Citizen's Electric Light and Power Co., of Hyde Park, for a central station plant of 120 arc lights and 1,200 incandescent lights. The new Wood arc and Slattery induction incandescent systems will be adopted in this station throughout. The central station is situated in Pullman, Ill., and will furnish service for lighting Pullman, Kensington, Roseland, Riverdale and other sections of Hyde Park.

The New Slattery Alternating Current Motor is spoken of as the greatest advance in this direction ever accomplished. It is now in operation in Ft. Wayne. Important features are claimed for it, notably that it will start from rest either with or without the full load and does not need to run synchronously with the generator but as regards operation and efficiency is exactly similar to the ordinary continuous current motors so widely used at the present day.

The Illinois Electric Material Co., 841 Rookery, Chicago, are now comfortably settled in their new offices and thoroughly ready for business in all kinds of electric light, power, and other supplies. They will be pleased to receive a call from their many friends and patrons and show them their numerous specialties. They now carry in stock ready for immediate shipment a full line of Bishop rubber covered wires and cables so widely known in every central station and many isolated installations. Their present excellent facilities enable them to fill orders right away upon their receipt, which is quite an important feature and much to be desired in the supply business, and one which is also highly appreciated by customers.

Mr. W. H. Harding, formerly secretary of the Baxter Electric Motor Co. of Baltimore, Md., has taken charge of the South Side Electric Company's new central station in Chicago. The plant is located on the corner of State and 20th streets, and will be equipped in the most modern and approved manner, everything pertaining to the best and latest ideas on central station building being added, and the station is expected to be a model one in the thoroughness and excellence of its steam and electrical equipment. It will have a capacity of 10,000 incandescent lights of the Ft. Wayne Electric Company's system so well and favorably known throughout the whole country. Already more than 2,000 lights have been applied for and the company are now covering the residence district of the aristocratic quarter.

The Detroit Motor Co., through Mr. W. S. Armour, their Chicago agent, have recently consummated one of the largest motor deals known. This outfit of motors is for the Columbia Theatre, and comprises one 10 h. p. for elevator work ; one 5 h. p. operating a 60 inch exhaust fan, one 5 h. p. running a 48 inch exhaust fan, these two running at a speed of from 500 to 600 revolutions per minute ; one 2 h. p. operating a 72 inch exhaust fan at a speed of 230 revolutions per minute, and 2 small fan outfits for the managers office. Among other sales is a 15 h. p. motor. This company has also placed a 5 h. p. machine in Wm. Switzer's machine shop at 22 and 24 Fourth avenue, and a 1 h. p. motor in Cutter & Crossett's factory on Franklin street, and also three 1 h. p. motors to run silver buffer and 36 inch exhaust fans.

The J. C. Walsh Gasoline Torch Mfg. Company are now in shape to fill the largest orders at shortest notice and are receiving numerous orders which they push through as fast as they come in. Great improvements have been made in the construction of their torches which are now made of one solid spun box, thereby obtaining a more perfect and handsomer article and one of greatly increased durability. When these torches were first placed upon the market, it was supposed that the main and principal channel of supply would be to the plumbers, but the promotors are agreeably surprised to find that their product is employed by every one for the finest and most delicate soldering work, which it performs in the best manner. In electrical work it fills a long felt want, making finer joints with ordinary solder than were heretofore obtained even with the employment of bismuth solder, which on account of its high price is almost prohibitive for ordinary work.

NEW ENGLAND TRADE NOTES.

The Thomson-Houston Electric Company is putting up a building at Lynn which will be devoted entirely to the manufacture of electric mining machinery.

Mr. Fritz Goldenzweig, a prominent electrical engineer, of Vienna, Austria, has been in Boston this week for the purpose of investigating electric light and railway appliances, with a view to the introduction of the best system in Vienna. He reports that Vienna intends in the near future to have an electric railroad system of from ten to fifteen miles.

The Essick Printing Telegraph continues to attract general attention, and this week a successful experiment was made of connecting Washington with Boston. Between New York and Washington, and New York and Boston, there have been instruments working perfectly for some time. A number of the railroad companies have carefully examined it, and are only waiting to have their orders filled. They see a great possibility for this instrument in helping them with their multitudinous correspondence along their various lines of railroad.

The Electric Gas Lighting Company of Boston, has secured the agency for Eastern Massachusetts of the well-known Perret automatic electric motors for all work, manufactured by the Elektron Manufacturing Company of Brooklyn, N. Y., and they intend to introduce them in connection with the Mason primary battery, for which they have also recently secured the agency for New England. They are now making arrangements for quite an elaborate display in their store to show off the merits of this excellent motor and the battery, and are already in receipt of several orders.

H. E. Swift & Company have been increasing their business so rapidly that they have found it necessary to seek larger quarters, and have taken a factory and offices at 34 Oliver street, Boston. The offices will be on the second floor and the factory, large enough to accommodate 100 hands, which is double of their present accommodation, will be on the top floor. Messrs. Swift & Company have recently admitted Mr. Walter L. Boyden as partner, and will continue the general manufacture of rosettes, fuse boxes, cut-outs, safety appliances and all incandescent light supplies in porcelain and wood. They are also at present introducing the Brodie "Tree Insulator," and have a large demand for it.

The American Circular Loom Company, of Boston, manufacturers of an improved insulated line wire, have received an order for nine miles o wire from No. 0000 to 0, from the Duquesne Traction Company of Pittsburg, Pa., for use on the Thomson-Houston Electric Railway in that city. The insulation in this wire is woven on instead of braided, which gives it a peculiarly tough finish, and makes it capable of withstanding an immense amount of abrasion. It has the appearance of a stout canvass sheathing around the conductor. The saturation of the cotton by the compound is also very thorough, and is fireproof as well as waterproof. The American Circular Loom Company bid fair to develop into one of the large insulated wire companies in a very short time, and have already a large amount of orders on their books.

The Eastern Electric Light and Storage Battery Co. of Lowell, chartered in November, 1889, was organized for the purchase of patent rights of the "Sorley" storage battery for the territory of New England, and since that purchase they have bought the one-fourth interest which the Anglo-American Co. of New York held in the Eastern Electric Light and Storage Battery Co. Increasing business made it imperative that the company should be in a position thoroughly to equip electric light plants, and with that end in view propositions were made to the firm of L. H. Derby & Co., electricians, at Lowell. The negotiations resulted in the purchase of the entire plant, and the firm, consisting of L. A. Derby, F. A. Derby and C. F. Morse, have entered the employ of the Eastern Electric Light Co., each assuming the heads of their respective departments, as heretofore. A few of the places that have been equipped by them are the Lowell Bleachery, the Lawrence Co., White Bros. & Co., tanners ; the Traders and Mechanics Insurance Co., J. Montgomery Sears' country residence, Southboro, Damon Safe Works, and several of the largest buildings in Boston.

EXCELSIOR ELECTRIC CO.

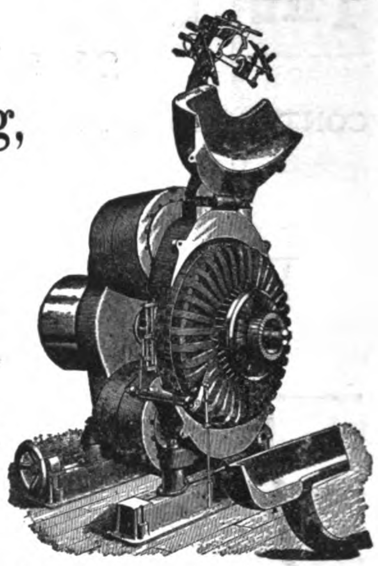
(HOCHHAUSEN SYSTEM.)

MANUFACTURERS OF

Arc and Incandescent Apparatus for Lighting,

ARC and INCANDESCENT MOTORS,

Electro-Plating and Electro-Deposition Machines.

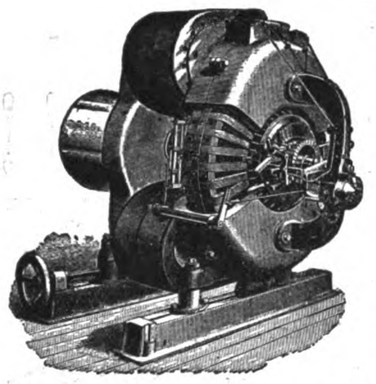


DISTINCTIVE FEATURES:

Lightest Weight, Largest Output,
Least Power Required,
Highest Efficiency and Least Floor Space.

MOST PERFECT AUTOMATIC REGULATION.

The New Arc Lighting System of this Company is the MOST SIMPLE, PERFECT and ECONOMICAL on the market.



For estimates and other information, address:

INTERIOR CONDUIT AND INSULATION COMPANY.

A NEW DEPARTURE IN INSULATION.

THE OLD PRACTICE abandoned because UNSAFE, UNRELIABLE, INACCESSIBLE and COSTLY.

THE NEW METHOD accepted instantly, because SAFE, RELIABLE, ALWAYS ACCESSIBLE and CHEAP.

A SIMPLE SOLUTION OF THE WIRING PROBLEM.

Electric Light Companies, Wiring Contractors, Architects, Builders, Insurance Inspectors and Owners

TAKE NOTICE!

You have one and all been asking for a System of Wiring that would relieve you from the annoyance, discredit and cost of existing methods. Such a System is hereby presented to your attention, and you are invited to give it your careful consideration.

UNDERGROUND CONDUITS.

THIS Conduit has been adopted for UNDERGROUND WORK as promptly as for Interior wiring, with not less REVOLUTIONARY and SUCCESSFUL results.

Cheapness, High Insulation and Durability Afforded.
Total Abandonment of Costly, Cumbersome and Perishable Cables.
Your Investment is in Copper Only.

THE INTERIOR CONDUIT AND INSULATION COMPANY are Manufacturers. Their Policy is to Deal only with the Trade, Selling on Commercial Discount Basis to all, without Restriction of any kind.

For Price List, Samples and General Information, address

ANOTHER TESTIMONIAL.

NEW BEDFORD GAS LIGHT COMPANY,
NEW BEDFORD, MASS., May 18, 1889.

A. F. Mason, General Manager:

DEAR SIR: Yours of May 9 is at hand. You ask me in regard to our opinion of the Simplex Wire, its economy, etc. In answer, I would say that our experience of the past year has taught us the necessity of the best insulation for both arc and incandescent wires, both in economy of coal consumed and in safety to life and property.

We have used your "Simplex Wire" on this account, and are perfectly satisfied, in fact I think our immunity from any accident the past year on the lines is largely due to your insulation. Yours truly, ROBT. B. TABOR.

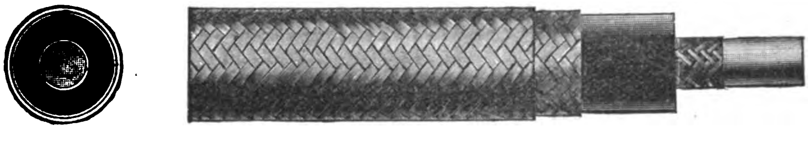
The "CLARK" WIRE



INSULATION GUARANTEED WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:
"A THOROUGHLY RELIABLE AND DESIRABLE WIRE IN EVERY RESPECT."

THE rubber used in insulating our wires and cables is especially chemically prepared, and IS GUARANTEED TO BE WATERPROOF, and WILL NOT DETERIORATE, OXIDIZE or CRACK, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, which is water, oil, acid, and to a very great extent fire-proof. OUR INSULATION WILL PROVE DURABLE WHEN ALL OTHERS FAIL. We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a WHITE OUTSIDE FINISH for ceiling cleat work as well as our standard color.

CLARK JOINT GUM should be used for making water-proof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass.

FOR RAILWAY AND MOTOR use, we make all sizes of stranded and flexible cables with Clark insulation. Wire Tables and price-list will be furnished on application to

HENRY A. CLARK, General Manager.
HERBERT H. EUSTIS, Electrician.

EASTERN ELECTRIC CABLE COMPANY,

ELECTRIC LIGHT.

The Standard Electric Company of Vermont has put in over forty plants during the past year, aggregating 10,450 lamps.

Navasota, Tex.—It is proposed to put in an incandescent plant in connection with the new water works, of which E. H. Haver is superintendent.

Braddock, Pa.—The Citizens' Electric Light Company, of Braddock, Pa., intend building a new station and will increase their plant by a Westinghouse 750 light alternating incandescent and a 50 light Thomson-Houston arc. W. S. Kuhn is the secretary of the company.

Pensacola, Fla.—The Pensacola Electric Light and Power Co. is doubling its plant, of the Thomson-Houston system, run by Ball engine and Schieren belting. Mr. E. G. Quina is the secretary and treasurer. The company has in use about 7 miles of circuit of underwriters' wire.

ELECTRIC RAILWAYS.

Japan.—K. Nakamura of Japan, is in this country to purchase equipment for a street railway at Tokio.

Milwaukee, Wis.—The consolidation of the Milwaukee City and Cream City railways has been effected. Both roads are owned by Eastern syndicates, and the deal is said to have been consummated in the East. It is reported that the Hinsey electric line is also included in the consolidation, but this is denied by Mr. Hinsey, who returned lately from the East. Both the Cream City and Milwaukee City lines will now be transformed into an electric system. The National Home and North Greenfield railroad company and the Milwaukee and Wauwatosa Motor line are about to pool issues and operate both systems under one management. The new deal contemplates the building of eleven miles of extra main and spur tracks at an additional cost, including equipment, of about $250,000.

CHICAGO. SAN FRANCISCO. DENVER. TORONTO, CAN.

ELECTRIC LIGHT.

Woodsville, Pa., is to have electric lighting.

Lansdale, Pa., is to have an electric lighting plant.

Keeseville, N. Y. is to have a Thomson-Houston plant.

Fort Worth, Tex.—Heck & Baker have a contract for street lighting.

Fairbury, Neb.—The City Council contemplates putting in an electric light plant.

Malvern, Pa.—An Edison Company is to be formed. It is promised a franchise.

Gordon, Pa.—Hon. D. D. Phillips is interested in a plant to be put in at a cost of $10,000.

Tarpon Springs, Fla.—The Occidental and Improvement Co. will put in an electric light plant.

Paducah, Ky.—The Paducah Gas Light Company is putting in a Thomson-Houston plant of 50 arcs.

Quitman, Ga.—A local company is to be given a 10 years franchise, and city lighting at $1800 a year.

Lock Haven, Pa.—Blanchard & Shultz, of Philadelphia, propose to establish a plant at Lock Haven.

Stuart, Ia.—N. Wilkin, of the Hawkeye Electric Manufacturing Co. proposes to start a plant at Stuart.

Blaine, Wash.—The Blaine Electric Light and Power Co. has been formed, with a capital stock of $50,000.

Como, N. J.—H. H. Yard is to put in a plant at Como, for lighting that place, Belmar, Spring Lake and Sea Girt.

East Forks, N. D.—L. P. Ordway, St. Paul, has made a proposition to furnish any electric light plant and water works.

Haywards, Cal.—The Haywards Electric Light Works have been started by S. D. Ingram, J. H. Farrell and D. Chisholm.

Dayton, Wash.—The Dayton Electric Light Co. has begun work on its station, and will put in a plant of 50 arcs and 600 incandescents.

Media, Pa.—The Media Electric Light Company will increase its plant this fall by putting in another dynamo and an engine of 50 h. p., etc.

The Wightman Electric Manufacturing Company has been formed at Scranton, Pa., by Merle J. Wightman and others, with a capital stock of $30,000.

Hoquiam, Wash.—The Aberdeen and Hoquiam Electric Railway Company will establish an electric light plant in connection with its street railway system.

Lake Geneva, Wis.—The Lake Geneva Water and Light Co. has been formed, with a capital stock of $40,000, by J. E. Heg, E. P. Wheeler and J. C. Reynolds.

Greenwich, Conn.—The Greenwich Gas and Electric Light Co., R. B. Owens, superintendent, has started up its Thomson-Houston plant very satisfactorily.

Milwaukee, Wis.—The Milwaukee Light and Power Company will put up a power house on Commerce and Galena streets, which is to be in readiness by September.

Louisville, Ky.—The Louisville Gas Company will locate the station it proposes to build for electric lighting on the site of the First Presbyterian Church, on Green street.

Chester, Pa.—The Chester Electric Light and Power Company of Chester, Penna., is increasing its facilities by putting in a larger engine and two additional dynamos.

Johnstown, N. Y.—The Johnstown Electric Light and Power Company has secured the contract for two years, at $75 per light per year, the company to supply 50 lamps or more.

Westerly, R. I.—The Westerly Gas and Electric Light Co. has elected for the current year E. Babcock, president; A. Perry, secretary and treasurer; and J. H. Hodgson, superintendent.

Elizabeth, N. J.—A syndicate of wealthy New York capitalists is said to have obtained control of the plant of the Schuyler Electric Light Company of Elizabeth, N. J. It will increase its capacity thrice.

Las Vegas, N. M.—J. H. Gates, Westinghouse agent, has secured an order from the Las Vegas Gas Co. for 40 arcs and 750 incandescents, both machines alternating, and for a 100 h. p. Westinghouse compound engine.

Rock Hill, S. C.—The Rock Hill Electric Light Co. has a capital stock of $10,000. J. M. Cherry has been elected president and D. Hutchison, secretary and treasurer. The company has not bought a plant yet, and is in need of a complete outfit.

New York City.—Judge Coxe has declined to grant the motion of the Brush Electric Light Co. for a rehearing on his recent decision in favor of the Brush-Swan Co. as sole agent in this district for apparatus and machinery manufactured by the defendant company.

Pittsburgh, Pa.—The Thomson-Houston Co. has closed a contract with the Pittsburgh Plate Glass Co., for its city works, for 1,356 incandescent lights and an electric tramway with four electric locomotives for hauling plate glass through the works. The plant requires 300 h. p. of engine, etc.

San Antonio, Tex.—The San Antonio Gas Co. bought recently the plant of the Electric Light and Power Co. It is remodeling the plant, and has ordered two 750 Westinghouse alternating lighters, a 320 h. p. Westinghouse compound condensing engine and a 700 h. p. Holyoke Deane condenser.

☛ **Binghamton, N. Y.**—The Binghamton Electric Company has been incorporated with a capital stock of $200,000. The corporation is organized for a term of fifty years, for supplying electric light. The following are directors: George J. Morse, Hyde Park, Mass.; Geo. W. Dunn, Geo. F. O'Neil and John Anderson, Binghamton; W. H. Roberson, Harry F. Roberson, Frank Sterry, Albany.

Kansas City, Mo.—The Interstate Electric Company of Kansas City, Mo., has assigned to William Allbritain. The property consists of a number of cells of storage batteries, wires already put up, and poles, office furniture and fixtures, machinery consisting of two steam engines and five boilers, a franchise from the city, some electrical lamps and electrical sundries, and some accounts, a total valuation estimated of $6,000.

Stoneham, Mass.—The reports given by the New England papers as to the rates for lighting the town of Stoneham by the Woburn Electric Light Co. appear to be incorrect. Instead of being 90 cents for a light to 12.30 a. m., the price of arc lights is about $87 per year, and is below the price named for lighting the town of Melrose, referred to at 60 cents a light; while the maximum price showed by the Malden Electric Co. (which lights Melrose) in its operations is $100 per light per year.

Atlanta, Ga.—The newly created Board of Electrical Control, Atlanta, Ga., recently held its first meeting in that city. Alderman J. G. Woodward, a chairman of the Light Committee, became ex-officio chairman; Chief of the Fire Department W. R. Joyn was made secretary; City Engineer R. M. Clayton is the other member of the board. Mr. W. B. Walker was elected superintendent of electrical affairs, and will take charge of all matters pertaining to electric wire and other apparatus that come within the jurisdiction of the city.

ELECTRIC RAILWAYS.

Great Falls, Mont.—The new electric road is to run to the Montana smelter and Giant Springs.

Oakland, Cal.—The Pacific Improvement Co. will change their road on Telegraph avenue either to electricity or to cable.

Salina, Kan.—The street railways are being consolidated by Eastern capital, and the United system is to be operated by electricity.

Columbus, O.—Mr. J. S. Crump will operate his new 4 mile road by horses at first, but it is his intention to adopt electricity ultimately.

Boise City, Idaho.—G. A. Insley, and others, have secured a franchise for an electric road, of which 2½ miles are to be finished within a year.

Atchison, Kan.—An electric railway company has been formed, with G. Storch, president; W. W. Hetherington, treasurer; and G. H. Williams, secretary.

Champaign, Ill.—The Champaign and Urbana street railway, owned by F. L. Jaques, has been granted permission to extend its lines, on condition that it will operate electrically within the next two years.

Danvers, Mass.—At a meeting of the stockholders of the Beverly and Danvers electric road, it was voted to ask the railroad commissioners for permission to increase their capital stock $18,000, making a total of $25,000. It was voted to build an annex to the present power station on Elliott street, for a waiting room and workshop. The directors were instructed to petition the selectmen of Danvers for permission to connect with and run over the tracks of the Naumkeag street railroad from Danversport to the plains. The directors were authorized to lease the road if they thought expedient.

Newark, N. J.—The Philadelphia syndicate which recently acquired control of the Essex (N. J.) passenger railway system and of the Newark and Irvington line has just completed the transaction by receiving nearly all the stock necessary to give them the syndicate ownership. Checks to the amount of $1,650,000 have been paid to John and Robert Ballantine, William Clark, A. Q. Keasbey, S. Battin, Andrew Lemassena, Wolcott Jackson, and others. The price of each share of stock was $350. A temporary organization has been effected, and a permanent organization will be had at a meeting to be held shortly. The new Board of Directors will have three representatives of the old companies.

Orange, N. J.—The Essex Passenger Railroad Company, whose line extends from Newark to Orange, has petitioned the Common Council of Orange for permission to operate its cars by electricity with the overhead system of wires carried on poles. The petition has been referred to the railroad committee, and will probably be adversely reported upon, the public sentiment in Orange, it is believed, being opposed to the overhead system of wires for running cars. The company, however, is going to operate its cars by that system in Newark, as are all the other street railroads there, the city authorities having granted that privilege to the syndicate which owns them, as well as the Essex Passenger Railway Company.

Lawrence, Mass.—One of the most important business transactions of late years was consummated on June 6 in the sale of the Merrimac Valley Horse R. R. to a syndicate of railway men of Boston and Newburyport. It is probable that the concern will be known as the Boston Construction Co. The sale made was of about 720 of the 800 shares of stock, the price said to be $150 a share. The par value is $100, and the last sales were made at $125. The road connects Lawrence with the outlying towns of Andover, Methuen and North Andover, as well as the suburbs, has been in operation 22 years, and under its recent management has greatly extended its track and increased its facilities. Franklin Butler, president of the board of trade, is president; Hon. Byron Truell, of the governor's council, vice-president, and A. C. Butler, cashier of the Arlington bank, treasurer. The sale is supposed to be part of the scheme for a route between Newburyport, Haverhill and Lawrence by a line of electric railway. Two other roads are alleged to be already under the control of the same syndicate. The sale was a great surprise to everybody.

Dublin, Tex.—The new street railway company, formed by A. A. Chapman, and others, has a capital stock of $15,000. The road will be 3 miles long, and it is proposed to operate it at first by mule power.

ELECTRIC POWER.

Chicago.—The Belding Motor and Manufacturing Co. state that they are thirty days behind their orders on motors.

Muskegon, Mich.—The Muskegon Machine and Foundry Company, of Muskegon, Mich., has been formed by the consolidation of two companies, one from Norwalk, Ohio, and the other from Toledo, Ohio, to engage in the manufacture of sewing machines and various kinds of light machines. A leading feature will be the manufacture of sewing machines and an electric motor to furnish power for the same.

TELEGRAPH.

The Telegraph Conference.—A special dispatch from Paris, of June 19, says: The telegraph conference to-day finally rejected the German proposal to double the price of code words; also the Austrian proposal that ten words be the minimum in a message; also the British proposal that five words be the minimum. A reduction of the tariff between England and Malta, Gibraltar, Spain and Portugal was announced.

WATER POWER.

Farmington River, Conn.—The new power company that is to use the power of the Farmington River, ten miles from Hartford, for generating electricity for the Hartford electric light station, has been duly organized. It is known as the Farmington River Power Company, with a capital of $80,000. The undertaking is an extensive one, as it is proposed to transmit a 3,000-volt current ten miles to a 250 horse-power motor in the electric light station at Hartford. The directors: J. L. Howard, E. C. Terry, W. H. Goodrich, L. A. Barbour, E. B. Bennett, Henry Roberts and Atwood Collins.

NEW HOTELS.

Abecon, N. J., is to have a new hotel with electric bells, etc.

Richland, Ga.—A new hotel and bank block is now being erected.

Fort Worth, Tex.—M. B. Lloyd, W. M. Harrison and others propose building a new hotel.

Barrow, Va.—The Barrow Improvement Company will build a $60,000 hotel with electric bells, etc.

Ellicottville, N. Y.—B. J. Crawford will build a new hotel with 61 rooms, and put in electric bells, etc.

Cleveland, O.—Putt & Wilmot's hotel, on Ontario and Prospect, is to be remodeled and to have electric lights, bells, etc.

Crawfish Springs, Tenn.—Gen. J. T. Wilder and others propose building a large hotel at Crawfish Springs, near Chattanooga.

Salt Lake City.—The new Hotel Ontario will be a 5-story building, costing $600,000. It will have electric lights, electric bells, electric annunciators, etc.

Chicago.—S. H. Gwathmey, will build a $100,000 hotel, called the Argyle, on 63d street, near the Eastern Illinois depot, to have electric lights, electric bells, annunciators, etc.

Chicago.—Goeffmey Bros. will build a 5-story and basement hotel on 63d street, near the Illinois Central Railroad depot, to cost $70,000. It will have electric annunciators, electric bells, etc.

Cumberland Island, Ga.—It is stated that T. Henley, G. M. Davis, C. A. Ellis and F. Whitehead, of Macon, Ga., propose building a summer hotel, etc., at Cumberland Island, near Brunswick.

Kensington, Ga.—The Kensington Land Company, F. R. Pemberton, president, is to build a hotel at a cost of $30,000, which will be lighted by electricity and contain electric bells, annunciators, etc.

NEW BUILDINGS.

Aurora, Ill., is to have a $75,000 government building.

Dubuque, Ia., is to have a new court house costing $125,000.

Pittsburgh, Pa.—The Baltimore and Ohio Co. will spend $400,000 on a new depot, etc.

Union City, Ind.—The Pythian Opera House Company will build a theatre and use electric lights in it.

Palmer, Mass.—The Memorial Building is to be equipped with electric lights. Mr. A. Pinney has charge of the matter.

Manitou, Col.—The Manitou Auditorium Co. has been formed to build a large hall, to cost $50,000. J. M. Hulbert is interested.

Findlay, O.—The Brilliant City Brewing Company, J. Stark, president, will build a fine brewery equipped for incandescent electric lighting.

Phœnix, Ariz.—J. D. Monihan is to build a lodge room and office block fitted up for incandescent light. Electric bells, etc., will also be put in.

ELECTRIC LIGHT.

Sherman, Tenn., has been enlarging its city plant.

Selma, Ala.—The Matthews Cotton Mill Company will put in an electric light plant.

Cartersville, Ga., is to have an electric light plant put in by capitalists of Rome, Ga.

Kimball, Tenn.—The Kimball Town Company proposes putting in an electric light plant.

New Decatur, Ala.—The Decatur Electric Light and Power Company will increase its plant.

Milledgeville, Ga.—The Milledgeville Electric Light Company is to put in a new incandescent machine, new engine boiler, etc.

Yazoo, Miss.—C. A. Collins, the chairman of the committee on street lighting, is inviting correspondence on the subject of electric lighting.

Three Forks City, Ky.—The St. Helen's Improvement Company, of 307 West Main street, Louisville, will put in an electric light plant at this new city.

Chicago.—S. S. Beman has made plans for a power house for the Edison Electric Light Co. to be erected on Twenty-sixth and Indiana avenue, 70 x 148 feet, at a cost of $18,000.

Morganton, N. C.—The contract for the electric light plant has been let to the Westinghouse Electric Light Company, of Pittsburgh, Pa. It is to have capacity for 25 arc and 750 incandescent lights.

Birmingham, Ala.—The furnaces of the Vanderbilt Steel and Iron Company, Birmingham, will be lighted by apparatus of the Easton Electric Company, of New York, purchased through the Southern agent, W. A. Wright, Birmingham.

Yazoo City, Miss.—L. M. Fishback, representing the Thomson-Houston Electric Company, of Boston, Mass., will, it is stated, submit a proposition to the town council for the erection of an electric light plant and the construction of water works at an estimated total cost of $40,000 to $50,000.

Concord, N. H.—The foundation for the new electric light station of the Concord Co. has been started. The building will be of brick, one story, the main part 68 x 90 feet with engine room in L. A 100 feet chimney will be erected. The power will be supplied by two new steel boilers, and one additional engine will be put in, besides several new dynamos. The work will be pushed rapidly, and it is expected to have the plant ready for operation by Sept. 15.

Oshkosh, Wis.—The Oshkosh Electric Light and Power Co. now has a capital stock of $60,000. C. C. Paige is president, superintendent, etc. T. D. Grimner is secretary and H. B. Hurshaw, vice-president. The plant is of the Thomson-Houston system, and comprises 300 h. p. of Ball engines, driven by Munson belts. Okonite and simplex wire is used, and there are over 65 miles of circuit. The company now propose extensive additions and are receiving proposals.

Santa Cruz, Cal.—The Swanton & Clark Electric Co. has organized as the Santa Cruz Electric Light and Power Co. H. H. Clark is president; J. F. Appleby, vice-president; A. P. Swanton, treasurer; F. W. Swanton, secretary; C. E. Lilly, electrician. A plant of the Thomson-Houston alternating system has been put in. It comprises also a Fraser Chalmers Corliss engine of 250 h. p., and a Taylor Beck engine of 85 h. p., with 3 Atlas boilers. The "Shield Brand" wire of the Electrical Supply Co. of Chicago is used.

ELECTRIC RAILWAYS.

Beverly, Mass.—The Naumkeag Street Railway Co. have bought the land for their large new power station.

Asheville, N. C.—The Asheville Street Railroad Company will extend its road to Biltmore, the winter seat of Mr. Vanderbilt.

Chicago.—The Cicero and Proviso Electric Street Car Co. have applied for permission to build their road. There will probably be no difficulty in the matter.

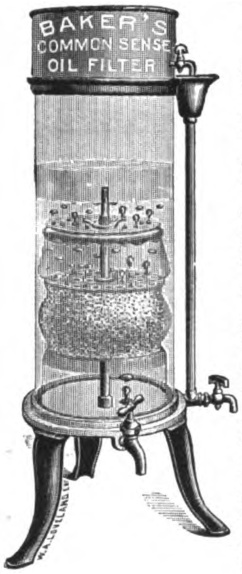
"NOT HOW CHEAP BUT HOW GOOD."

THE BAKER
Common Sense Oil Filter.



10 Reasons Why You Should Buy It.

1.—It will save wasting a large share of your oil, that costs money.
2.—It will allow the operator to use oil as freely as is necessary.
3.—It insures parts running cool that are liable to heat.
4.—It saves extreme close attention, as oil can be fed better in a moderate quantity than when stinted very close.
5.—It saves trouble, stops, and costly delays.
6.—It saves repairs, and extends the life of your machinery.
7.—It filters the oil so thoroughly that it is as good as new.
8.—It allows the same oil to be used from five to forty times.
9.—It is the only Oil Filter that has the whole operation visible, and this makes it an unqualified success.
10.—It will soon pay for itself in $'s and requires little care.

CONNECTORS AND TERMINALS,
For all Electrical Purposes. Incandescent Lamp and Cut-Out Terminals for all makes of Lamps.
General Electrical Supplies.
The C. McINTIRE CO., 13 and 15 Franklin St., Newark, N. J.

Marion, N. C.—The Marion Street Railway and Hotel Company has a capital stock of $100,000, and will build an electric or dummy road one and one-half miles long.

North Yakima, Wash.—W. Ferguson. L. Mac Lean, C. V. Massey, and others, of Spokane Falls, will build an electric road at Yakima, where they are interested in real estate.

Lowell, Mass.—The Lowell and Dracut Street Railway Co. will, it is said, put in a power plant for their road instead of taking their power as heretofore from the electric light station.

The Wheless Electric Railway Co. has been formed at Alexandria, Va., with a capital stock of $1,750,000. Mr. J. L. Beach represents the company, which has been trying its system in Washington with success.

Long Island City, N. Y.—There was to be a hearing at 2 P. M. on June 16 before the Railroad Commission in Albany on the application of the Long Island City and Newtown Street Railroad Company for permission to change its motor power from horses to electricity.

South Baltimore, Md.—The Baltimore, South Baltimore and Curtis Bay Railway Company has been formed, with a capital stock of $50,000, and with W. S. Rayner as president and W. C. Pennington as secretary. It intends building a five mile electric road to Curtis' Bay.

East Orange, N. J.—The East Orange Township Committee is considering the request of the Essex Passenger (horse-car) Railroad Company for leave to extend its lines further through the township, and also to erect poles and wires for the purpose of running its cars by electricity.

Brockton, Mass.—The electric road between Whitman and Brockton is given up for a time, and nothing will be done in carrying out the plans this year. The trouble lies mainly in the slowness of the selectmen in granting a franchise. The road will probably be finished sometime next spring in order to start up for the summer travel.

Electric Light Installations

AND THE

MANAGEMENT OF ACCUMULATORS.

A PRACTICAL HAND-BOOK

BY

Sir David Salomons, Bart. M.A., Asso. Inst. C.E.

Member of Council of the Society of Telegraph Engineers and Electricians. Member of the American Institute of Electrical Engineers.

FIFTH EDITION, REVISED AND ENLARGED.

With 99 Illustrations.

D. VAN NOSTRAND COMPANY,

PUBLISHERS,

23 Murray and 27 Warren Sts.,

NEW YORK.

New Bedford, Mass.—The Union Street Railway Co. of New Bedford is making necessary repairs, previous to operating cars by electricity. No poles have been set yet. The work of laying the ground wire between the rails is progressing. Five new box cars fitted with motors have arrived. No open cars will be fitted with motors for the present.

Topeka, Kan.—General Manager Patten, of the Topeka Rapid Transit Railway, says: "An experience of twenty-five years with horses on roads in the East, and one year with electricity, leads me to believe that for a road having business sufficient for ten cars, electricity is far more economical, efficient and in every way superior to any other known motive power."

THE GETHINS IMPROVED GRAVITY BATTERY

ESPECIALLY ADAPTED FOR CLOSED CIRCUIT WORK.

MANUFACTURED BY

THE GETHINS ELECTRICAL MFG. COMPANY,

620 ATLANTIC AVE., BOSTON, MASS.

The Best Battery in the World for Fire Alarm, Police Signal, Railway Signal and Telegraph Work of all Kinds. Thousands of Batteries now in Use in all parts of the United States, and Giving Perfect Satisfaction.

ATTENTION IS CALLED TO THE FOLLOWING TESTIMONIAL:

POLICE DEPARTMENT OF THE CITY OF BOSTON,
SIGNAL SERVICE OFFICE,
(A) PEMBERTON SQ., April 17, 1890.

To the Honorable the Board of Police Commissioners:

GENTLEMEN:—I herewith report that the Gethins Gravity Batteries placed in Station 10, Jan. 17, 1889, were recharged with new elements of the same kind April 4, 1890, having shown a constant service of fourteen months, eighteen days. As the service of a battery is in proportion to the work done, I would state that during that time there were received 2,357 wagon signals, 12,237 telephone signals, and 198,486 "on duty" signals. As each signal will average ten breaks of the current this would indicate an armature movement of 2,131,160 times. As compared with the Standard Crowfoot battery, the best record in this service is seven months, twenty-three days.

Respectfully submitted,
(Signed) HENRY A. CHASE, Electrician.

PRICE LIST (subject to change).

Glass Jars	.80	Zincs	.85
Porous Cups	.50	Battery containing above parts	1.25
Coppers	.15		

Battery, without 6 x 8 glass jars, 1.00.

Discount to trade. All goods sold ex store, Boston, Mass.

Quantity of chemicals required for running battery 15 months:
Four pounds blue vitriol.
One ounce of sulphate of zinc.
Three ounces of mercury.

We can furnish above supplies if desired at market prices. The company is now prepared to furnish to parties desiring the same composition zincs at forty cents each. These zincs are a composition of zinc and mercury, and when used no mercury is required in setting up the battery, but this zinc should be occasionally amalgamated.

Hamilton, Ont.—The capital stock of the Hamilton Electric Light Co. has been increased from $200,000 to $300,000.

Crosby ✦ Dry ✦ Battery

FOR OPEN CIRCUIT WORK.

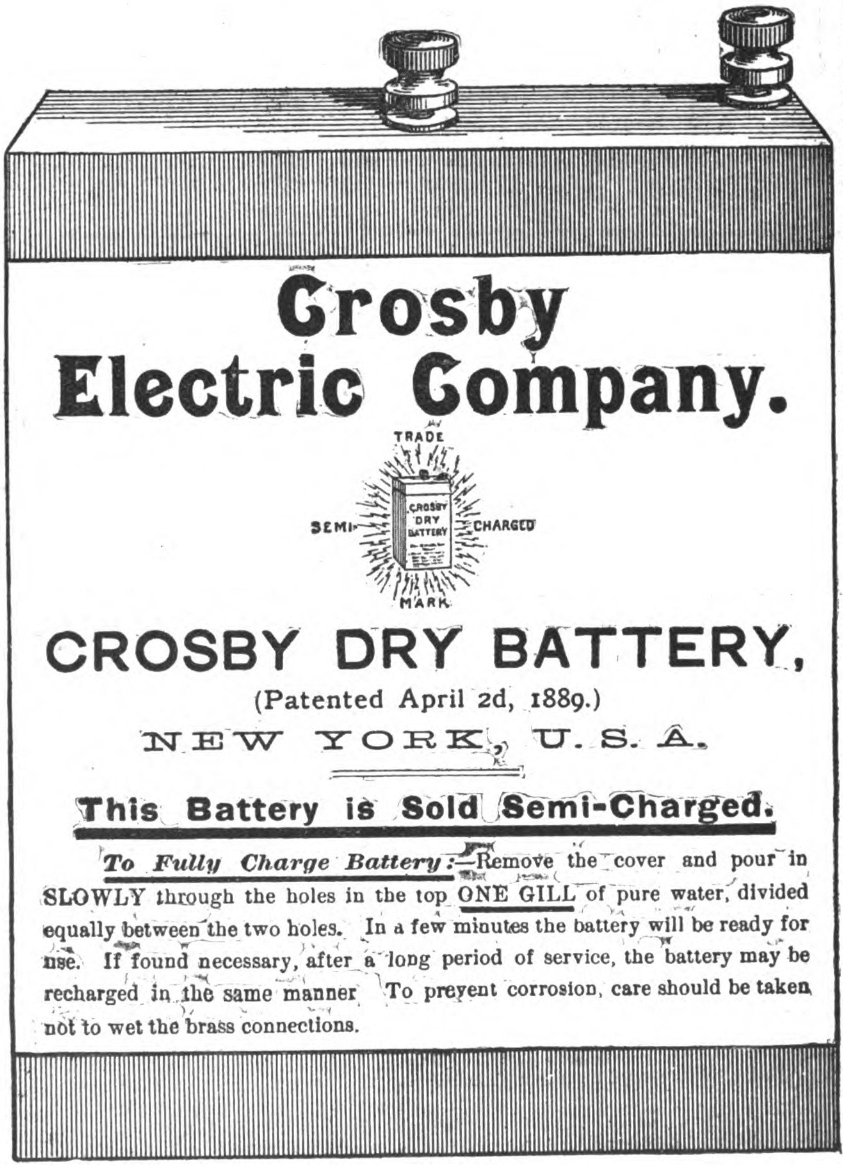
Electromotive Force, 1.55 Volts. **Current, 1 to 10 Amperes.**

Advantages of the Crosby Dry Battery for Open Circuit Work.

The Crosby Dry Battery is the **best Open Circuit Battery in the market.** It possesses all the advantages claimed for any Open Circuit Battery, and is capable of performing more work than any other. In addition to this, it is the **most reliable, most compact, most durable** and **simplest** cell yet discovered It is so constructed that **it is not destroyed** or seriously injured by **short circuiting,** and we are prepared to prove at any time that its **power of recuperation** is proportionately **greater** than that of any other. For Electric Bell, Gas Lighting, Burglar Alarms, Annunciators, Telephones, Microphones, Medical Electrical Purposes, Electrical Clocks and all the uses to which Open Circuit Batteries may be put. **It has no equal,** whether it be compared with **Liquid** or **other Dry Batteries.** We guarantee **depolarization, absence of offensive crystallization and perfect cleanliness.**

The Crosby Battery is the only Dry Battery sold **semi-charged. It does not work until wanted.**

The preference **as between Liquid and Dry Batteries** should always be given to the latter, provided the amount of working power required and a constant current can be obtained. **No form of Dry Battery has as yet been placed** before the public, except the **Crosby Dry Battery,** which will do the work of wet batteries and **give a constant supply of Electricity sufficient for reliable Open Circuit work at all times.** The advantages of a Dry Battery are obvious, because wet batteries, of whatever form, are constantly giving out offensive odors and spoiling everything with which their fumes come in contact. They are disagreeable and uncleanly machines, unsightly in appearance and easily broken and injured. **The Crosby Dry Battery is perfectly clean, emits no destructive gases or acids,** and, after once being properly connected, **requires no attention whatever,** while the liquid batteries are frequently in need of being cleaned, and the solution used must constantly be renewed.



CROSBY DRY BATTERY,
(Patented April 2d, 1889.)
NEW YORK, U. S. A.

This Battery is Sold Semi-Charged.

To Fully Charge Battery:—Remove the cover and pour in SLOWLY through the holes in the top ONE GILL of pure water, divided equally between the two holes. In a few minutes the battery will be ready for use. If found necessary, after a long period of service, the battery may be recharged in the same manner To prevent corrosion, care should be taken not to wet the brass connections.

The Crosby Battery is not affected by temperature; whether hot or cold, it is equally capable of performing the work for which it is intended.

The Crosby Dry Battery is only intended for **Open Circuit Work.** If, however, through an accident, it becomes **Short Circuited, it recoups itself.** This cannot be said with equal truth of any other dry battery known.

The Crosby Dry Batteries are manufactured in different sizes and forms, to suit the needs of different purchasers. The quantity of current required for any given work can be secured by a change in the form and size of the battery. For ringing bells and work of that character, the Cylindrical Batteries are to be preferred; but in instances where very low internal resistance is desired, as in telephone work and for medical electrical purposes, the Rectangular form is the better.

The quantity of current in the **Crosby Dry Batteries varies from one to ten amperes,** according to the size and shape, while the electromotive force remains constant at 1.55 volts

---

[*Copy.*]

OFFICE OF FLEMING'S ELECTRO-MEDICAL INSTRUMENT M'F'Y. No. 1009 Arch St., Philadelphia, March 8, 1890.

CROSBY ELECTRIC COMPANY, NEW YORK.—*Gentlemen:* The opportunity of expressing to you my views in reference to the Dry Cells made by your firm gives me great pleasure, and I do not hesitate in describing my experience with some of them. I charged and connected one of your No. 2 square cells with one of my rapidly interrupted 4-ohm resistance primary coils, starting it Jan. 28, 1890, at 4 P. M., kept running all night and following day, Jan. 29, when at 4 P. M. it became accidentally short-circuited, remaining so until 6 P. M. The cell was then released and allowed to recuperate till Jan. 30, 7.30 A. M., started again, **and left running until Feb. 13, stopping during night time. Thus, in defiance of a two-hour short circuit, this cell functioned = 371 consecutive hours, a result never before attained in all my experience with open circuit battery cells. The same cell, being recharged afterwards, still retains its working capacity, apparently as good as previous to its testing.**

Very respectfully,
(Signed), OTTO FLEMING.

JAMES H. MASON, MANUFACTURING ELECTRICIAN,

Office, 63 Broadway, New York.

THE attention of all dealers in electrical supplies, electric lighting and power companies, contractors, etc., is called to our

TESTED FUSE WIRE,

AND

AMERICAN SAFETY FUSES.

Aware of the trouble caused by the unreliability of the fuse wires now on the market, we have decided to introduce a superior grade of TESTED FUSE WIRE and FOIL FUSES.

Every spool of wire supplied by us has been tested at several points and its actual fusing point under varying conditions and advisable carrying capacity determined. These tests are made in the testing department of this company and a certificate accompanies each spool or coil sold, giving the results of the test. This wire is sold by the foot or pound. In ordering state the carrying capacity desired.

Our FOIL FUSES are made of an alloy foil mounted on asbestos and coated with an asbestos compound.

The ordinary fuse wire or foil has a fusing point varying with its length, position (open air or closed box), and the temperature of the surrounding air. Our foil fuses, called the

AMERICAN SAFETY FUSES,

are by their construction entirely independent of these conditions.

They are packed in boxes of various lengths and grades for all the smaller carrying capacities, carefully tested, and the boxes marked with the results of the tests. Send for prices.

Owners of the only Protector which received the **unqualified official approval** of the Boston Board of Fire Underwriters.

BOSTON BOARD OF FIRE UNDERWRITERS, 55 KILBY ST., Room 63,
ELECTRICAL SAFETY CO., H. E. TOWNSEND, Esq., *Treasurer.* BOSTON, April 21, 1890.

DEAR SIR:—In reply to your favor of this date, permit me to say that the Cartwright Electrical Protector submitted by your company at the recent test of Electrical Safety Devices made by the Boston Fire Underwriters' Union, is reported to us as having met, in a satisfactory manner, all the conditions of the test, and the use of the said Protector will be approved by our Inspectors.

I am, yours truly, (Signed) OSBORNE HOWES, JR., Secretary.

Liberal arrangements made with responsible parties desiring to form sub-companies for certain specified territory.

146 FRANKLIN STREET, (Room 21), BOSTON, MASS.

WILL YOU BUY

AN Incandescent Lamp, claimed to take a SMALL AMOUNT of CURRENT at first, but which really takes DOUBLE THAT AMOUNT after a comparatively SHORT SERVICE;

OR

AN Incandescent Lamp taking a MODERATE and UNIFORM AMOUNT of current, and giving LONG LIFE at its rated candle power

?

THE

Westinghouse Electric Company's

ALTERNATE CURRENT SYSTEM OF

INCANDESCENT ELECTRIC LIGHTING

WARRANTS YOUR MOST CAREFUL INVESTIGATION.

Three years ago half a dozen Central Station Companies running a few thousand lights had adopted it. To-day it is in use in three hundred towns and cities, and about 600,000 sixteen candle-power lamps is the aggregate capacity of the three hundred plants.

The first dynamos the Westinghouse Electric Company made are still in operation, but the improvement since that time has been great. Electrically and mechanically perfection has been attained.

The converters of The Westinghouse Electric Company have the highest attainable efficiency and are from ten to fifteen per cent. better in this respect than those of other manufacturers.

No central station can be operated to advantage without the Shallenberger Meter. No gas company, however small, would think of operating a station without meters, and the same reasoning is applicable to all electric light plants. Send for special circular on the Shallenberger Meter.

The Westinghouse Electric Company was the pioneer in the manufacture of Alternate Current Dynamos in America, and all of its apparatus is celebrated in this country and abroad for its durability, efficiency and the satisfaction it has given to purchasers.

The Westinghouse Electric Company has recently utilized the alternating current for Arc Lighting. Send for special circular just issued. A simple single carbon lamp runs four nights without renewal of carbons. Dynamos of the following capacities constantly kept in stock, together with a full outfit of detail apparatus and lamps:

25, 40, 60, 125, 250.

No wall fixtures are required in the Alternating Arc System.

The machine is inherently self-regulating from full load to short circuit.

Ampere Hours Can be Read Off the Dials, same as a Gas Meter.

COUNTERS ARE SENT OUT ALL READY TO SET UP, BEING FULLY TESTED AND GUARANTEED CORRECT.

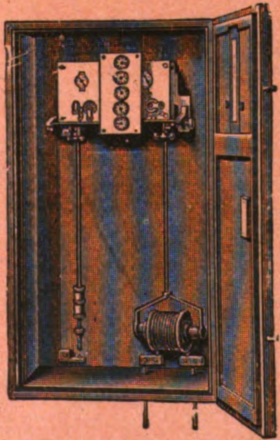
No Chemical Analysis. **No Photo Process.**

Opinions of Electric Light Companies.

NEW HAVEN, CONN., May 13, 1890.

We beg to state that the Aron Meters furnished this Company have given good satisfaction, and after testing them for nearly a year, we are satisfied that they are accurate in their measurements, and not liable to get out of order.

NEW HAVEN ELECTRIC Co.



MONTREAL, May 12, 1890.

I have much pleasure in stating that the Aron Meters for alternating currents which you sold me, one of which is in use in the Bank of Montreal, have proved the most accurate and reliable of three kinds of which I can speak from personal experience. The Aron Meter possesses the very important advantages over others that, no matter how great the range of the instrument, it commences to register with one lamp in circuit, it does not whirl along registering for some time after the lights have been shut off, and it consumes less energy than any other recording instrument of which I have knowledge.

A. J. LAWSON.

MANCHESTER, Conn.

We find that the Aron Counters register as accurately as is necessary for the purpose to which such meters would be applied. We have perfectly satisfied ourselves of their adaptability.

PROF. WM. A. ANTHONY,
Mather Electric Light Co.

BROOKLYN, N. Y.

We have four Aron Counters in use for some months, during which time no trouble has been experienced in regard to care of same, and satisfactory readings have been obtained.

C. J. FIELD, Gen. Man. Edison Illuminating Co.

Every large user of Electric Light should demand the use of this Counter.
